1.0 TRANSMISSION SYSTEM PLAN

The sections contained in this Exhibit form Hydro One's consolidated five-year Transmission System Plan ("TSP") for the 2020 to 2024 period (the "planning period"). The TSP has been prepared in accordance with Chapter 2 of the Ontario Energy Board's *Filing Requirements for Electricity Transmission Applications*, issued on February 11, 2016, with further guidance from Chapter 5 of the OEB's Filing Requirements (*Consolidated Distribution System Plan Filing Requirements*), issued on March 28, 2013 and revised on July 12, 2018 (together, the "Filing Requirements"). To assist parties in their review of the TSP, Hydro One has provided the applicable references to the Filing Requirements in brackets in the heading titles throughout the TSP.

On March 16, 2018 the OEB issued a letter setting out its expectations regarding future distribution rate and transmission revenue requirement applications by Hydro One. The letter directed Hydro One to file a transmission revenue requirement application for a four-year period from 2019 to 2022. Subsequently, Hydro One experienced organizational changes in July and August, 2018, which included the appointment of a new Board of Directors. As a result, Hydro One took the opportunity to re-evaluate its transmission business plan to balance the needs of customers, system reliability and overall stewardship of its assets with a particular focus on increasing productivity and minimizing rate increases.

To permit this review to occur and adhere to the OEB's objective of a combined transmission and distribution application in the future, Hydro One adopted a two-step approach. First, Hydro One filed an application for a one-year mechanistic adjustment to Hydro One's 2019 revenue requirement (EB-2018-0130). Second, Hydro One filed this 3-year Custom Incentive Rate- Setting (IR) application with a 2020-2022 test period to allow alignment with the OEB's expectation that Hydro One file a single application for distribution rates and transmission revenue requirement for the period 2023 to 2027.

Consistent with Chapter 2 of the Filing Requirements, Hydro One's TSP includes a summary of capital expenditures for five future years. However, this Application seeks approval for a revenue requirement only in respect of the 3-year period of 2020-2022. The terms "planning period" and "test period" are used accordingly throughout the TSP.

The table of contents for the TSP is provided below.

1.1 (5.2.1) TRANSMISSION SYSTEM PLAN OVERVIEW

1.1.1 (5.2.1 A) INTRODUCTION

This is the first 5-year Transmission System Plan ("TSP") prepared by Hydro One Networks Inc. ("Hydro One"). It covers a planning horizon from 2020 to 2024. Hydro One has prepared this TSP in accordance with Section 2.4 of Chapter 2 (Revenue Requirement Applications) of the Ontario Energy Board's (the "OEB" or "Board") *Filing Requirements for Electricity Transmission Applications*, issued on February 11, 2016, with further guidance from Chapter 5 of the Filing Requirements (Consolidated Distribution System Plan Filing Requirements), issued on July 12, 2018 (together, the "Filing Requirements"). The references in heading brackets denote corresponding sections of the Filing Requirements.

Consistent with the Filing Requirements, this TSP provides a consolidated set of documentation concerning Hydro One's asset management process and capital expenditure plan for its transmission system, using a standardized approach and structure. This TSP also provides related information about Hydro One's efforts to coordinate its planning with third parties, identify and take into account customer preferences, as well as measure performance to support continuous improvement.

This TSP provides a comprehensive and detailed explanation of Hydro One's capital investment plan for its transmission system in respect of the 5-year period from 2020 to 2024. Based on OEB Staff input from its letter dated March 16, 2018, and in light of subsequent organizational changes experienced by Hydro One in July and August 2018, Hydro One adopted a two-step approach. First, on October 26, 2018, Hydro One filed an application for a one-year mechanistic adjustment to determine Hydro One's 2019 revenue requirement (EB-2018-0130). Second, Hydro One is submitting this 3-year request for revenue requirement covering the period 2020-2022. This is done to align the completion of the transmission revenue requirement period with that of the Hydro One Distribution application filed on March 31, 2017 under case number EB-2017-0049, which aligns with the OEB's expectation that Hydro One file a single application for distribution rates and transmission revenue requirement with a test period commencing in 2023. For clarity, while the revenue requirement application covers the period 2020-2022, this TSP, and the capital investment plan discussed herein, covers the 5-year period from 2020-2024 in accordance with the Filing Requirements.

This plan demonstrates how Hydro One has aligned its investment planning processes and intended outcomes with the principles and expectations articulated by the OEB in the *Renewed Regulatory Framework* ("RRF"),[1] namely by focusing on identified customer preferences; continuous improvement in productivity, reliability and cost performance; public policy responsiveness; and financial performance.

To prepare this TSP, Hydro One engaged its transmission customers, its Executive Leadership Team and employees from across the company, including functions such as Planning, Customer Care, Finance, Transmission and Stations, System Operations and Regulatory Affairs. Through this significant effort, Hydro One has endeavored to carefully consider and set out, in extensive detail, its proposed transmission investment plans over the course of the planning period, along with the myriad of processes, methodologies and other considerations that, together, have enabled Hydro One to ensure its investment plans are appropriate in their focus, scope and pacing, having regard for the needs of the system, the company and its customers. Hydro One engaged in benchmarking and third party assessments to provide feedback on the condition of its assets, the strategies and approaches it employs to manage those assets and to ensure that a consistent and thorough planning process is in place. The assessments demonstrate that

[1] OEB, Report of the Board - Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach, October 18, 2012.

recent enhancements to Hydro One's planning practices and processes address gaps identified both internally and by the OEB in the Prior Proceeding, and that the investment planning process is aligned with industry best practices.

1.1.2 (5.2.1 A) FORMAT OF THE TSP

Consistent with the Filing Requirements, Hydro One's TSP is organized into three chapters, as follows.

- **Chapter 1 – Transmission System Plan** – This chapter provides an overview of Hydro One's transmission system and the various factors and outcomes that were considered by Hydro One in developing its capital expenditure plan.
- **Chapter 2 – Asset Management Process** – This chapter reviews Hydro One's asset management and life-cycle optimization strategies, as well as its investment planning process, which determines the appropriate portfolio of investments having regard to the specific outcomes that Hydro One seeks to achieve;
- **Chapter 3 – Capital Expenditure Plan** – This chapter details Hydro One's capital expenditure plans for its transmission system for the period 2020-2024 and compares Hydro One's historical capital spending to past OEB-approved forecasts. The capital expenditure plan is the product of the investment planning process and asset management strategies described in Chapter 2, as informed and guided by the various drivers described in Chapter 1. This Chapter includes a number of Investment Summary Documents, which provide details regarding large projects with forecast spending over $3 million[2] in any given year of the 2020-2024 period.

A Table of Concordance, which aligns the sections of this TSP with the Filing Requirements, is provided in Appendix 'A'.

Unless otherwise specified, the asset information contained in this TSP is taken as of December 31, 2018. Forecast costs for the 2019 to 2024 period are as forecast in Hydro

[2] Hydro One's materiality threshold is $3 million as determined Section 2.1.1 of the OEB's Filing Requirements for Electricity Transmission Applications, dated February 11, 2016.

One's 2019-2024 Transmission Business Plan.[3] 2018 costs are based on Hydro One's Q3 forecast of 2018 and will be updated with actuals in a Blue Page update to be completed in mid-2019.

[3] The Transmission Business Plan, dated December 14, 2018, is provided as Attachment 1 to Exhibit A, Tab 3, Schedule 1.

1.1.3 RESPONSIVENESS TO OEB DECISION IN EB-2016-0160

The OEB's findings and directions in its Decision and Order on Hydro One's last transmission revenue requirement application (EB-2016-0160), have informed the preparation of this TSP. Table 1 below identifies the OEB's TSP-related areas of concern in that proceeding and describes at a high level how Hydro One has responded to that feedback in preparing the present application. Each of these aspects is elaborated upon throughout this TSP.

Table 1 – Summary of Responses to OEB Feedback on TSP in EB-2016-0160

AREA OF CONCERN	OEB FEEDBACK	HYDRO ONE ACTIONS TAKEN
Customer Engagement	The investment plan did not adequately use customer engagement feedback	Earlier, more comprehensive customer engagement Customer engagement feedback results used to inform and update risk taxonomies in line with customer needs Increased Customer Participation: Representatives from 103 customer organizations participated in the 2017 survey, relative to 62 organizations in the 2016 survey
Deficiencies in Prioritization	Questioned prioritization and optimization process	New taxonomies drive investment scoring and prioritization and optimization; Risk scores used to maximize risk mitigation per dollar spent
Asset Condition Assessments	Need a comprehensive asset condition process that informs the prioritization	Risk scores tied back to available condition assessments; Updated inventory of assets and condition assessments with identified opportunities; Third-party assessments and data initiatives performed.

AREA OF CONCERN	OEB FEEDBACK	HYDRO ONE ACTIONS TAKEN
Value Added in Review	The investment plan did not change over seven months of review	Enterprise Wide Review: Multiple challenge sessions are now held to provide a fact-based and structured approach to define the investment portfolio, with the focus on ensuring that the most valuable work to customers is included in the plan.
Sequencing	Plan was submitted for rate filing before Hydro One Board approval	Sequencing issues addressed for this filing. Plan submitted to Hydro One Board of directors in December 2018, in advance of filing
Internal Audit	Planning process had outstanding internal audit items to address	All original internal audit items are now complete; Follow up internal audit shows lower overall risk level
Work Program Delivery	Hydro One had not historically delivered its capital and OM&A programs to OEB approved level	Enhanced upfront engineering and planning deliverables; Increased governance throughout investment lifecycle; Improved estimating and scheduling tools and processes Delivered In Service Addition ("ISA") approved in 2017 rate order (872M vs. 868M) 2016 Bridge year ISA presented as part of EB-2016-0160 (910M vs. 912M)

1.1.4 (5.3.2 A, B) HYDRO ONE'S TRANSMISSION SYSTEM

This section of the TSP provides a high level description of Hydro One's transmission system, its role in Ontario's electricity system and the customers it serves. This description is provided, in part, to provide insight on how the transmission system differs from distribution systems and their associated distribution system plans. Chapter 5 of the Filing Requirements for distribution system plans was used to prepare this TSP, however, the unique aspects of Hydro One's transmission system were also necessarily taken into account in developing this TSP. Key aspects to consider include:

- Hydro One's transmission system extends to most of the province and operates in diverse geographic and climatic conditions, unlike distribution systems which generally serve smaller and more localized service territories;
- Hydro One's transmission system is a critical asset for the province, with a particularly high level of criticality for certain areas and facilities, such that significant and far-reaching impacts are likely to result from outages;
- one particularly critical aspect is the part of Hydro One's transmission system comprising the bulk electric system, which requires compliance with reliability standards established by the North American Electric Reliability Corporation ("NERC") to ensure the integrity of the interconnected North American Bulk Electric Systems;
- as the lead transmitter for most regions in the province, Hydro One must take into account Regional Planning requirements and the Long-Term Energy Plan ("LTEP") in planning its transmission investments;
- customers served by Hydro One's transmission system include large industrial end users, which depend on a reliable energy supply and high-power quality to support their facilities and industrial processes, as well as the owners and operators of local distribution systems that in turn serve end-users across the province; and
- Transmission projects tend to be multi-year in nature, as opposed to distribution projects which tend to be completed within a 12-month period.

These aspects are discussed in the sections below.

1.1.4.1 SCOPE OF THE TRANSMISSION SYSTEM AND SERVICE AREA

Hydro One is comprised of over $13 billion of transmission assets and accounts for approximately 98% of the revenues of all licensed transmitters in Ontario. The system transmits electricity throughout the Province of Ontario between supply points (i.e. generation) and delivery points (i.e. load customers). In 2017, Hydro One transmitted approximately 132 TWh of electricity, directly or indirectly, to substantially all consumers of electricity in Ontario.

As shown in the maps provided in Figures 1 and 2, below, Hydro One's transmission service area includes both northern and southern Ontario. Whereas the majority of Ontario's population is located in the south, the northern part of the province is sparsely populated with heavy forestation. The climate across Ontario also varies significantly by location and by season. Hydro One's transmission system is susceptible to a variety of extreme weather conditions, such as blizzards, hail, ice storms, lightning, thunderstorms, extreme heat and tornadoes.

Hydro One operates its transmission system and manages responses to trouble calls from a centralized operations facility known as the Ontario Grid Control Centre ("OGCC"). A Back Up Control Centre ("BUCC") is also maintained in accordance with NERC standard Emergency Operating Procedure, EOP-008-2 "Loss of Control Centre Functionality" and the IESO Market Rules. In the event the OGCC or its computer systems are rendered unavailable, control and monitoring of the bulk electric system or IESO-controlled Grid is transferred to the BUCC. In addition, Hydro One has Service Centres located throughout the province, which serve Hydro One's transmission business as well as its distribution business, provide base locations for field crews and the materials, tools and equipment they rely upon to provide maintenance and restoration services in a timely, effective and efficient manner. Support for Hydro One's transmission system operations is provided by various corporate functions, including executive leadership, finance, human resources, legal and regulatory, which carry on business from Hydro One's head office in downtown Toronto.

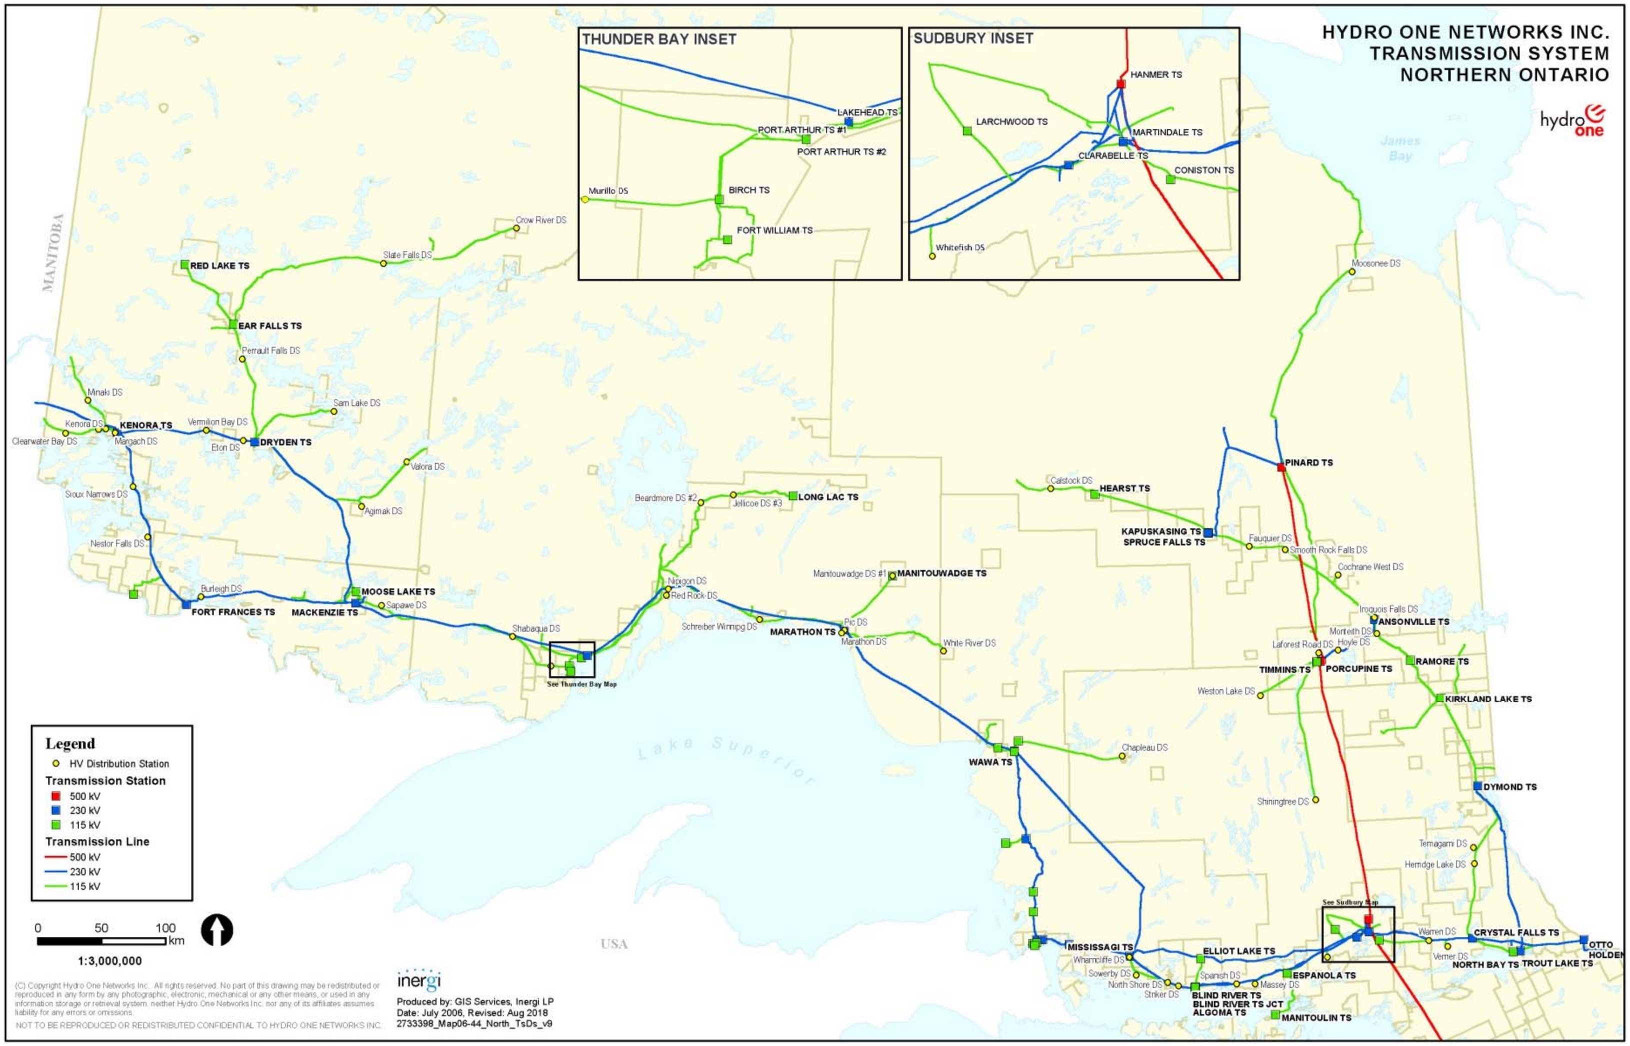

Figure 1 – Hydro One Transmission System in Northern Ontario

Figure 2 – Hydro One Transmission System in Southern Ontario

In addition to providing connections to its customer base, Hydro One's transmission system is connected with and enables the operation of all other licensed transmission systems in Ontario, namely those that are owned and operated by Canadian Niagara Power Inc., Five Nations Energy Inc., Hydro One Sault Ste. Marie LP (formerly Great Lakes Power Transmission LP), and B2M Limited Partnership.

Hydro One's transmission system interconnects with transmission systems in five neighbouring jurisdictions in Canada and the United States (Manitoba, Quebec, Minnesota, Michigan and New York) and enables electricity transactions with those jurisdictions through 26[4] interconnections, as shown in Figure 3, below. Collectively, these interconnections can accommodate theoretical maximum imports of about 6,610 MW and exports of approximately 6,121 MW of electricity in the summer months.[5] Actual import and export capabilities of the interconnections depend on limitations at the interface as well as within Hydro One's system and the transmission systems in other jurisdictions.

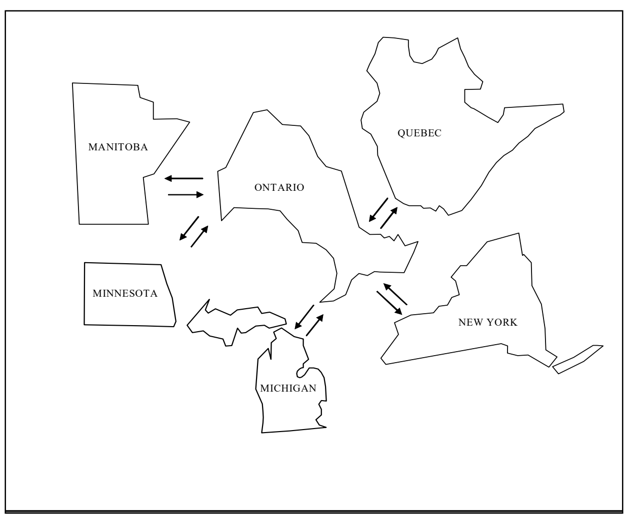

Figure 3 – Existing Ontario Transmission Interconnections

[4] The number of interconnections will increase as a result of the Lake Erie interconnection project (SS-03).
[5] From the IESO Ontario Transmission System report June 20, 2018

Hydro One's transmission system is generally comprised of three types of infrastructure – transmission lines, transmission stations and network operations facilities. A simplified figure showing how the transmission system is configured, relative to the generating stations and distribution systems that it serves, is provided in Figure 4, below.

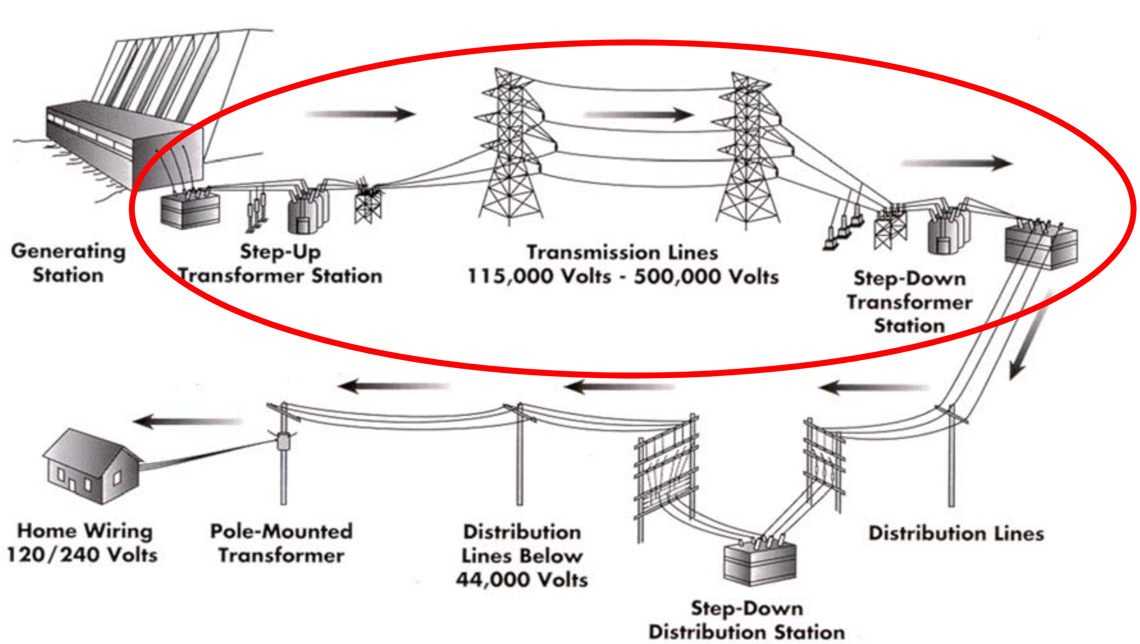

Figure 4 – Schematic Diagram of Hydro One's Transmission System

Hydro One operates transmission lines primarily at 500 kV, 230 kV and 115 kV, with minor lengths operating at 345 kV. These lines are used to transmit electric power to connected industrial and commercial customers, as well as to LDCs who in turn distribute the power to end-use customers. Hydro One's bulk transmission lines (discussed further below) deliver power from generating stations or connections to receiving stations. Area supply lines take power from the network and transmit it to customer supply transmission stations at customer load centres. Almost all of Hydro One's transmission lines are overhead. Approximately 69% of the overhead transmission lines are erected on steel structures with the other 31% supported by wood pole structures (primarily for the 115kV system).

The major components of transmission lines include overhead conductors, underground cables, steel and wood pole structures, foundations, insulators, shield wire, switches and line hardware. Transmission lines are located on lands owned either by the Ontario government, Hydro One or other parties with whom Hydro One has agreements with respect to occupancy and access rights. Approximately 70% of the delivery points on Hydro One's transmission system are multi-circuit delivery points, meaning more than one line is normally available to supply the customers connected to such a delivery point. The remainder of the transmission system features single-circuit delivery points. The high proportion of multi-circuit delivery points on Hydro One's transmission system enables Hydro One to provide a high level of reliability for the customers that it serves.

Along with high voltage transmission lines, transmission stations are the other broad category of infrastructure that is critical to the function of Hydro One's transmission system. Transmission stations are used for the delivery of power, voltage transformation and switching, and serve as connection points for load and generator customers, as well as neighbouring Ontario transmission systems and neighbouring provincial and state jurisdictions.

Hydro One's transmission stations are designed based on a range of transformer and breaker configurations to ensure redundancy, such that a loss of any one element (such as a transformer or a breaker) at a transmission station will not result in the interruption of service to customers under normal conditions. Redundancy also allows for assets to be removed from service for maintenance without an interruption to Hydro One's ability to provide transmission service to customers. This capability helps support reliability. The major components of transmission stations include power transformers, circuit breakers, disconnect switches, bus work, insulators, power cables, surge arrestors, capacitor banks, reactors, station service, grounding systems, protection and telecom systems, site infrastructure and buildings.

Hydro One's network operations are carried out from the Ontario Grid Control Centre, which manages all of Hydro One's transmission operations. As noted, Hydro One's system also includes a Back-Up Control Centre to support reliable operation of the system.

In addition to high voltage lines and transmission stations, Hydro One's transmission business requires a fleet of general plant assets (including real estate and facilities, transport and work equipment, as well as information technology), which do not directly form part of the transmission system but are critical to its function and reliability. A snapshot of Hydro One's key transmission system-related assets is presented in Table 2, below.

Table 2 - Hydro One's Key Transmission System Assets

System Assets	Total
Operating Centres	2
Transmission Circuits (Total Number)	515
Length of Overhead Transmission Lines (Total Circuit km)	29,107
Length of Underground Transmission Cables (Total Circuit km)	264
Transmission Stations (Total Number)	294
Installed Transformer Nameplate Capacity (MVA)	118,735

Data as of December 31, 2018

1.1.4.2 CRITICALITY OF THE TRANSMISSION SYSTEM

Given the scope of Hydro One's transmission system and the scale of the territory that it serves, Hydro One's transmission system is critical infrastructure for the Province of Ontario. The role of Hydro One's transmission system within the province is consistent with the definition of "critical infrastructure" that has been adopted by the Province for purposes of the Ontario Critical Infrastructure Assurance Program, which considers such infrastructure to include "interdependent, interactive, interconnected networks of institutions, services, systems and processes that meet vital human needs, sustain the economy, protect public safety and security, and maintain continuity of and confidence in government".[6] It is because of this critical role in Ontario's electricity system that the transmission system has been referred to as the "backbone" of Ontario's electricity system.[7]

Relative to the numerous distribution systems that serve individual communities throughout Ontario, there is perhaps a greater need to ensure the reliability of Hydro One's transmission system. A strong recognition of this need was a defining characteristic for how the transmission system, which Hydro One inherited from the former Ontario Hydro, was initially designed and it has been a quality that has endured ever since. With this focus and the historical experience of transmission customers in Ontario, these customers have expressed a strong preference for a low frequency of outages and a high level of reliability. These objectives are supported by the high degree of redundancy that is built into the design of Hydro One's system. Hydro One's transmission system, particularly in the southern portion of Ontario, provides customers with a high level of redundancy that ensures a level of reliability that is proportionate to the system's critical role within the province.

In addition to Hydro One's objective of continuing to ensure a high level of reliability for the transmission system to meet customer expectations and preferences, Hydro One's approach to maintaining, managing and investing in its transmission system is driven by its need to comply with a framework of reliability standards that specifically applies to those portions of its system that are part of the bulk electric system ("BES"). Hydro One applies the NERC definition of the BES that was approved by the Federal Energy Regulatory Commission ("FERC") effective July 1, 2014. NERC defines the BES as

[6] See https://www.emergencymanagementontario.ca/english/emcommunity/ProvincialPrograms/ci/ci.html
[7] Ontario's 2010 Long-Term Energy Plan: Building Our Clean Energy Future, p. 41.

including all transmission facilities greater than 100 kV, which encompasses the vast majority of Ontario's (and Hydro One's) transmission facilities.

The reliability framework for Ontario's electricity transmission system is based on the reliability standards established by NERC, which have been adopted and are enforced in Ontario by the IESO. These standards are intended to ensure the integrity not only of the Ontario BES but of all of the interconnected BESs across North America. To achieve this, among its many activities, NERC develops and enforces reliability standards, monitors the bulk power system, assesses and reports on future transmission and generation adequacy, and offers education and certification programs to industry personnel.

NERC works with eight regional entities to improve the reliability of the bulk power system, including the Northeast Power Coordinating Council ("NPCC"). NPCC develops regional reliability standards, monitors and enforces compliance, and coordinates regional system planning, design and operations, and assessments of reliability. Hydro One is a member of NPCC and is registered under NERC's compliance registry.

Following the 2003 Northeast blackout, the U.S. *Energy Policy Act of 2005* authorized the creation of a self-regulatory Electricity Reliability Organization ("ERO") that would span North America, under the oversight of FERC in the U.S. The legislation states that compliance with reliability standards is mandatory and enforceable. In July 2006, Federal Energy Regulatory Commission ("FERC") certified NERC as the ERO in the United States. In October 2006, the OEB signed a memorandum of understanding with NERC recognizing NERC as the ERO in Ontario. According to this memorandum of understanding with NERC and the IESO's Market Rules, only the IESO is directly subject to the Compliance Monitoring and Enforcing Program of NERC and NPCC in Ontario. The IESO through its Market Assessment and Compliance Division, in turn, enforces the NERC reliability standards and NPCC criteria through the Market Rules.

As a licensed transmitter, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards adopted by NERC and NPCC. Hydro One actively participates with the other transmission system owners and operators on NPCC committees and task forces to coordinate planning and operations in the northeast region. There are approximately 90 Hydro One transmission stations[8] that include assets designated as part of the BES. To comply with NERC and NPCC reliability standards, these BES stations are equipped with multiple, redundant and robust protection and control systems to ensure that faults are isolated so as to prevent cascading and damage to assets near the fault. Infrastructure relating to key sites and processes is designed to adhere to NERC Critical Infrastructure Protection ("CIP") requirements. For example, sites subject to NERC and/or NPCC requirements require additional equipment, such as protection systems and station battery systems, and must meet additional CIP requirements, such as physical and electronic/cyber-security to prevent unauthorized network access. Hydro One's maintenance and investment plans are prioritized so as to maintain compliance with these requirements.

1.1.4.3 (5.2.1 G) CONSIDERATION FOR REGIONAL PLANNING AND LTEP

One of the key guiding principles from the Board's RRF is that planning transmission infrastructure with key stakeholders in a regional context helps promote the cost effective development of electricity infrastructure in Ontario. The RRF states that infrastructure planning on a regional basis, between licensed transmitters and distributors, is to be undertaken to ensure that regional issues and requirements are integrated into the utility's planning processes.

Consistent with the important role that Hydro One's transmission business plays in Ontario's regional planning process, as well as in bulk system planning, the Chapter 2

[8] Designation of BES facilities is based on the BUS structures. Some Hydro One stations contain more than 1 BUS network.

Filing Requirements identify distinct elements that must be included in a TSP but which are not required in a distribution system plan. The TSP reflects the company's discussion of needs identified through the regional planning process, the needs and preferences of customers, overall system planning policy objectives, and commitments arising from the Long Term Energy Plan. With respect to regional planning, a TSP is specifically required to include lead transmitter documentation for all applicable regions.[9]

There are a total of 21 regional planning zones in Ontario.[10] Given Hydro One's role as the lead transmitter for 19 of these regional planning zones, the extent to which regional planning has been considered in preparing this TSP is greater than the effect of regional planning on a typical distribution system plan. As described in TSP Section 1.2, there are a total of forty-six transmission investments arising from Hydro One's involvement in regional planning initiatives that it proposes to put into service during the 2020 to 2024 planning period. In a distribution system plan, a distributor is expected to describe its involvement in any regional planning initiatives and provide a copy of the final deliverables from such initiatives or the status thereof. Whereas Ontario's distributors may be involved in regional planning initiatives in respect of perhaps one or two regional planning zones, as the upstream transmitter for all of the regional planning zones, Hydro One has participated in regional planning working groups for 19 of the 21 regional planning zones. As such, Hydro One's transmission business is actively involved in the regional planning process and leading the development of regional infrastructure plans.

1.1.4.4 (5.2.1 G) TRANSMISSION-CONNECTED CUSTOMERS

Another important distinction between Hydro One's transmission system and the distribution systems that are the subject of the distribution system plans that the OEB typically reviews is the range of customers served. Whereas an LDC typically serves a

---

[9] Chapter 2 Filing Requirements, Section 2.4.2, p. 14.
[10] See Appendices 3 and 4 in Planning Process Working Group Report to the Board – The Process for Regional Infrastructure Planning in Ontario, May 17, 2013.

range of customers including residential, commercial, municipal and smaller industrial customers, and small embedded generation facilities, the customers served by Hydro One's transmission system are comprised of large electricity generators, large industrial end-users, and Ontario's LDCs. In addition, Hydro One's transmission system includes inter-jurisdictional interties that are relied upon by the IESO to balance electricity supply with system demand.

Depending on the configuration and ownership of a customer's facilities, Hydro One provides its transmission customers with one or more of the following transmission services:

- Network Connection Service – for use of assets built for the common benefit of all customers;
- Line Connection Service – for use of facilities that step down the voltage from above 50 kV to below 50 kV;
- Transformation Connection Service – for all other assets not included in the Network Connection or Line Connection pools – generally those assets built for use by a specific customer(s); and
- Wholesale Revenue Meter Service – for parties that purchase electricity in the IESO-administered markets or directly from a generator.

A profile of the customer base connected to Hydro One's transmission system is presented in Table 3, below.

Table 3 – Hydro One's Transmission-Connected Customers[11]

Customer Type	Number Served
Generators	131
End Users (Large Industrial Customers)	84
Local Distribution Companies	42

Generation customers that are directly connected to Hydro One's transmission system have a combined generation capacity of approximately 35,441 MW, which represents approximately 96% of the total generation capacity[12] in the Province of Ontario. These vital assets include most of Ontario's hydroelectric generation facilities, all natural gas fueled generation facilities, large renewable generation facilities and all of Ontario's nuclear generation facilities. A transmission outage affecting service to one of these facilities affects the generation supply for Ontario, which can affect the reliability of supply and the price of electricity for all Ontario customers. Moreover, transmission outages can affect generation facility equipment and cause those stations to shut down for extended periods at a significant cost to generators, which costs may ultimately be borne by ratepayers. These customers are actively engaged in the energy sector and, as such, are sophisticated and well aware of the trade-offs between cost and reliability risk.

The large industrial customers that are directly connected to Hydro One's transmission system are a critical part of Ontario's economy and, together, accounted for 1,785 MW of electricity demand in 2017, with an estimated 4% direct contribution to Ontario's GDP and a 28% contribution to Ontario's industrial GDP. These include, for instance, customer facilities for steel production, auto manufacturing, pulp and paper, chemical processing and mining. Typically, reliability and power quality for these large industrial customers are significant factors for their decisions to locate in and remain located in

[11] The number of customers in this table is based on the number of Transmission Connection Agreements (TCA) as required by the Transmission System Code ("TSC") with the exception of LDCs that are based on their Electricity Distribution License as of December 31, 2018. This differs from the number of business entities surveyed in the Customer Engagement survey, 156, as many entities hold multiple TCAs.
[12] Total Generation Capacity of Ontario is 36,928 MW (Source: IESO Reliability Outlook Winter 2018, December 17, 2018).

Ontario. Transmission outages or power quality issues can cause significant and costly interruptions to industrial processes and customer equipment, which in turn can affect company safety, performance, and employment. Hydro One developed a plan that brings reliability and power quality to these customers and which supports their businesses and Ontario's economy. These customers are sophisticated and well aware of the trade-offs between cost and reliability/power quality risk.

The LDCs that are served by Hydro One's transmission system serve most of Ontario's residential, commercial, institutional and small industrial end-users. The end-user facilities that are indirectly affected by the reliability and performance of Hydro One's transmission system include critical infrastructure such as telecommunications systems, water and wastewater treatment facilities, hospitals and other health care facilities, airports and transportation systems, schools and universities, as well as financial services systems. Like Hydro One's generation customers, these LDC customers are actively engaged in the energy sector and, as such, are sophisticated and well aware of the trade-offs between cost and reliability risk. So too are the neighbouring Ontario transmitters that are connected to Hydro One's transmission system, who would themselves have customers that include generators, large industrial customers and LDC customers.

1.1.5 (5.2.1 A) SUMMARY OF THE INVESTMENT PLANNING PROCESS

This section provides a summary of Hydro One’s investment planning process, including (i) Hydro One’s strategic priorities and the key elements of the OEB’s policy framework that have informed the process, (ii) the outcomes that Hydro One seeks to achieve by implementing the investments identified through the process, (iii) the manner in which Hydro One has engaged with customers and factored the resulting feedback into its process and investment plans, (iv) the manner in which regional planning considerations have been addressed, (v) the key steps and outputs from its investment planning process, and (vi) the key aspects of the proposed capital expenditure plan arising therefrom.

1.1.5.1 STRATEGIC OBJECTIVES

The investment planning process that has informed this TSP was guided by a list of strategic priorities. These priorities are as follows:

Strategic Priorities

- **Employees**
  - Maintain a safe and inclusive workplace for all employees
  - Foster a high level of employee engagement throughout Hydro One through a new engagement approach focused on developing company –wide action plans ("Time for Action")
- **Customer Experience**
  - Deliver industry-leading customer service, in response to identified customer preferences
  - Foster innovation in the business to adapt to changing customer requirements and market opportunities
  - Advance reconciliation and work proactively to build relationships with Indigenous peoples and communities based on understanding, respect and mutual trust
- **Operational Effectiveness**
  - Invest in grid infrastructure and grid modernization to deliver a high level of reliability and quality to our customers
  - Focus on continuous improvement in productivity and operating efficiency to maintain lowest possible costs
- **Government and Regulatory Relationships**
  - Maintain and build constructive, transparent relationships with governments and regulatory entities in all jurisdictions where we operate
  - Deliver on obligations mandated by government through legislation and regulatory requirements
- **Financial Strength**
  - Maintain a strong balance sheet to support continuing investment in our business
  - Invest in assets to better serve customers

SAFETY COMES FIRST | STAND FOR PEOPLE | EMPOWERED TO ACT | OPTIMISM CHARGES US | WIN AS ONE

Figure 5 – Hydro One's 2018 Strategic Priorities

Figure 6 highlights the close alignment between Hydro One's planned transmission investments and the company's strategic priorities.

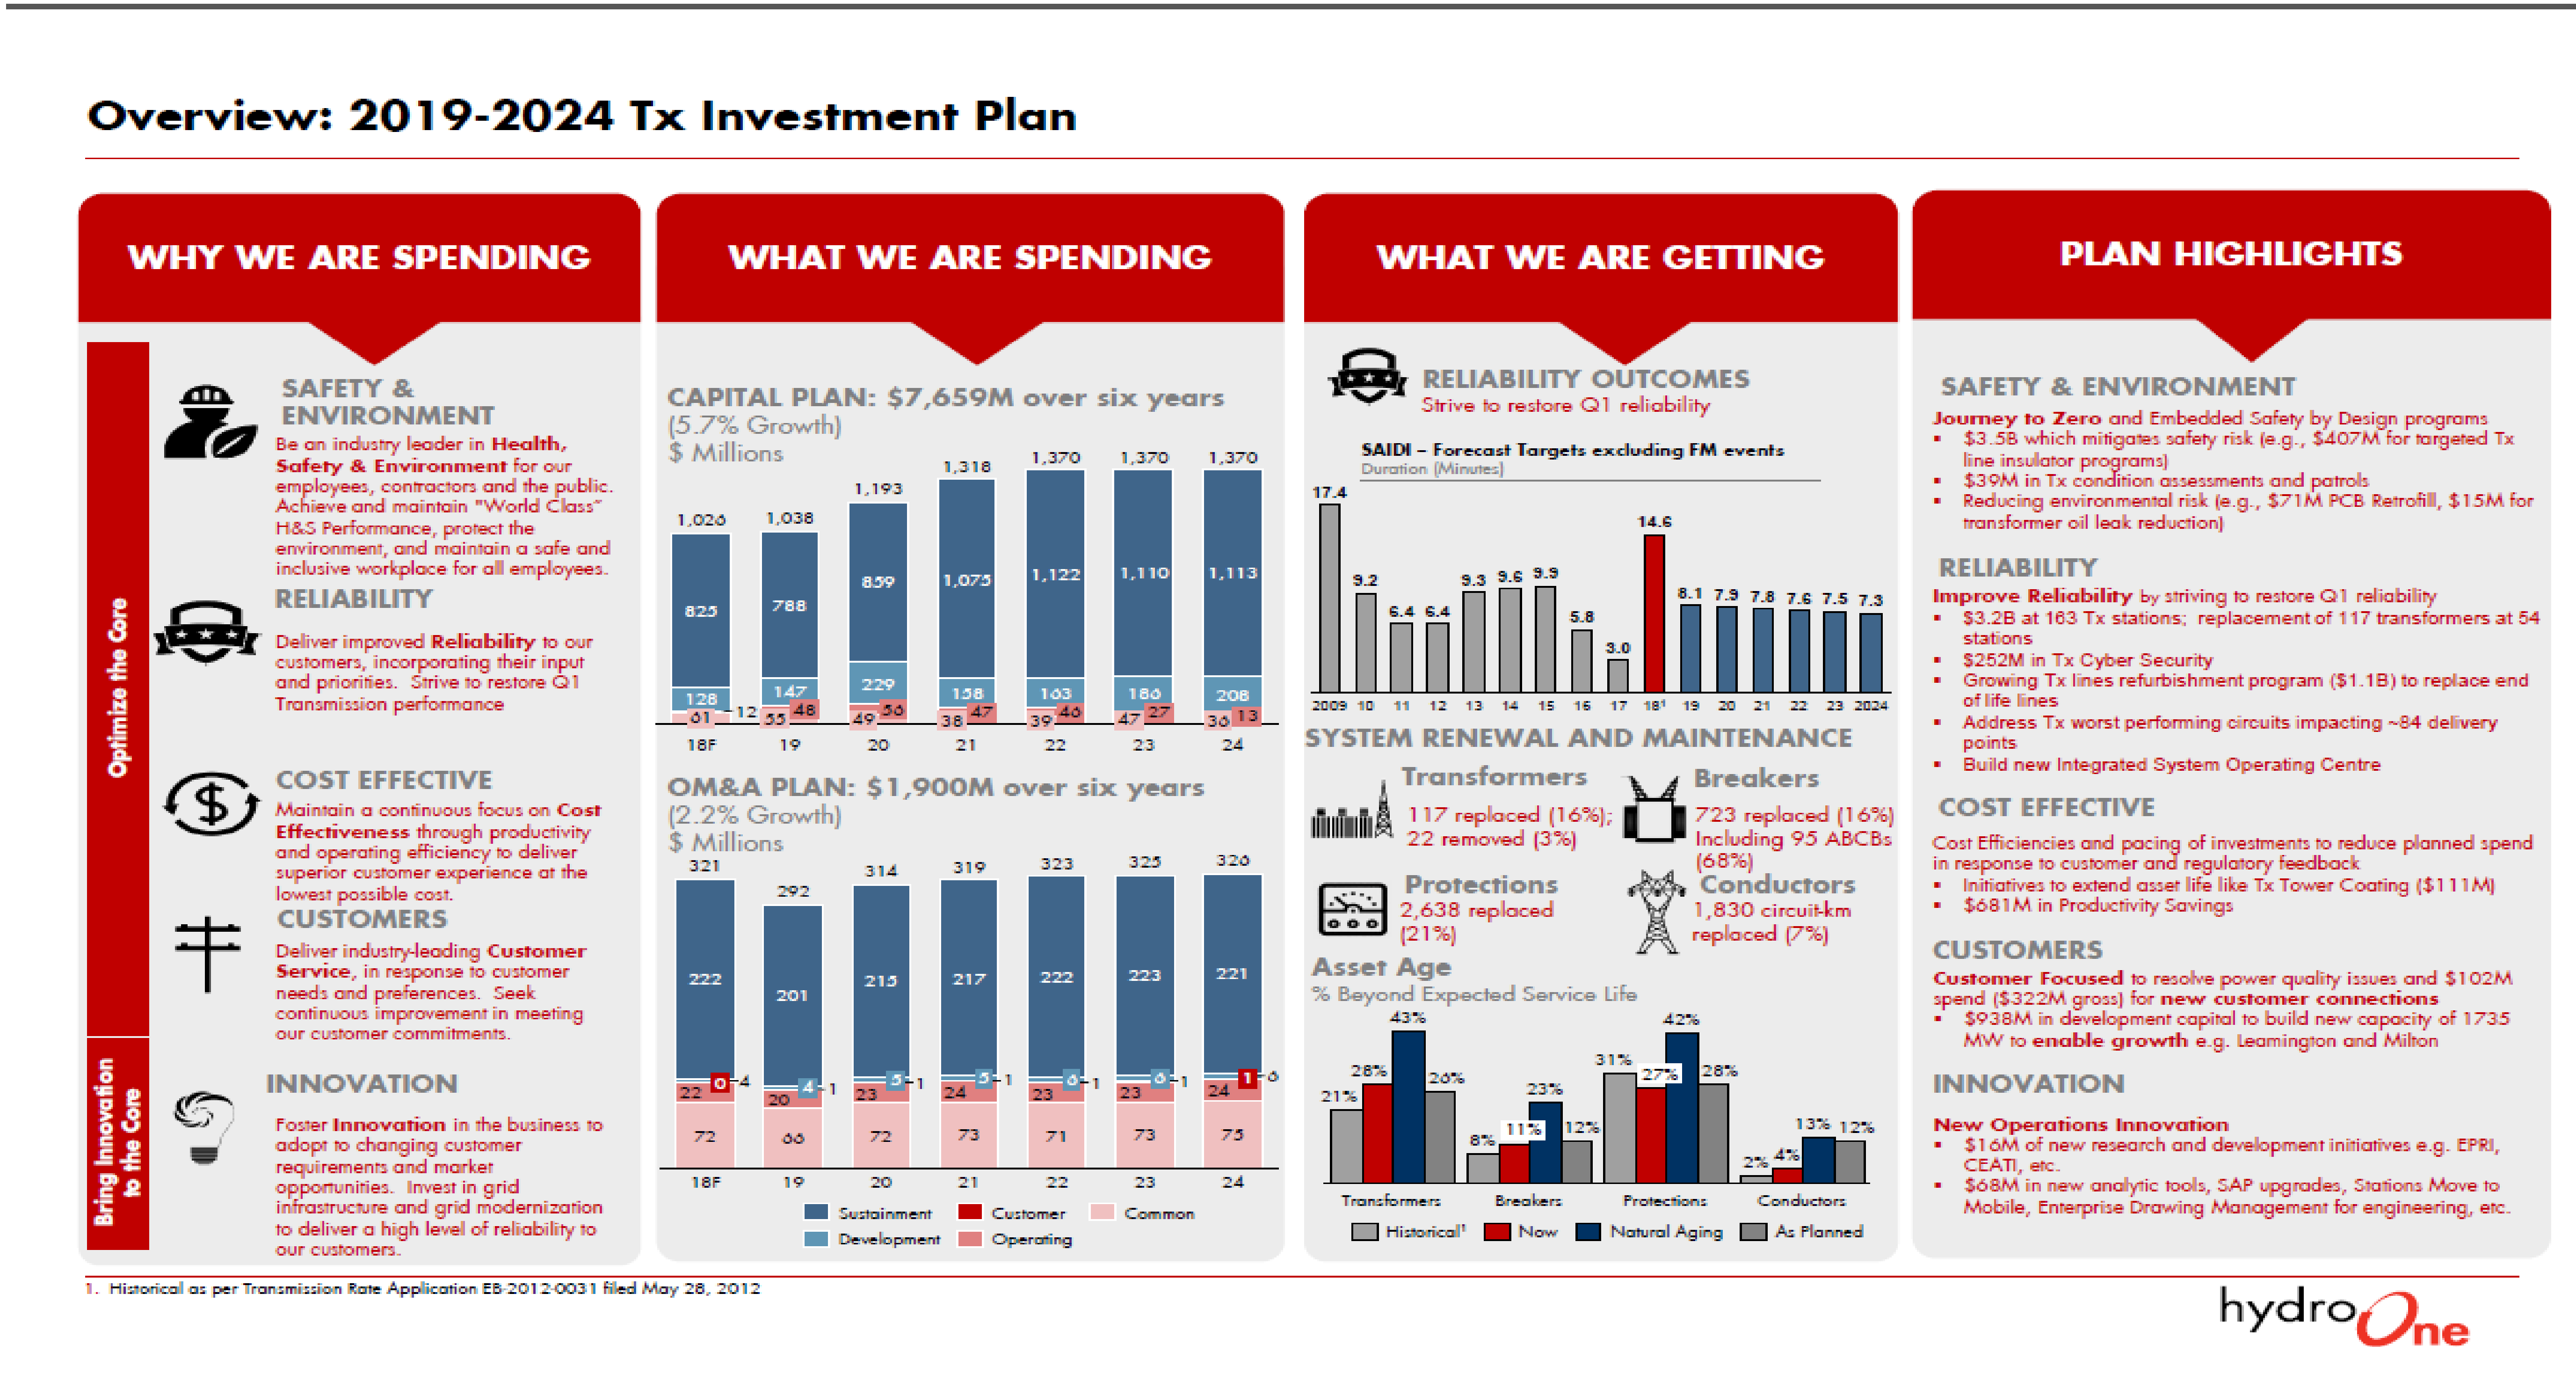

Figure 6 - Alignment Between Strategic Priorities and Planned Transmission Investments

These strategic priorities and objectives, together with the guidance provided by the OEB's policy framework, in particular, customer engagement, helped inform the investment plan that is included in this TSP. Moreover, there is close alignment between the company's priorities and objectives and the themes and outcomes that the OEB has articulated through its policy framework, discussed below.

1.1.5.2 POLICY FRAMEWORK

In this TSP, Hydro One recognizes and seeks alignment with the policy framework established by the OEB through the RRF and related guidance. Hydro One understands, and has made significant efforts to embrace, the objectives of the RRF in planning and operating its transmission system. In particular, Hydro One has developed an outcomes-based plan that provides value to its transmission customers by being responsive to their identified needs and preferences, addressing regional and bulk system needs and specific system access requirements, driving productivity improvements and promoting innovation and continuous improvement.

Through this approach, Hydro One is confident that it has achieved an appropriate balance between the imperatives of meeting its compliance requirements, providing prudent stewardship over its transmission system assets, responsibly managing health and safety risks, responding to customer needs and preferences, and achieving sustainable financial performance.

Accordingly, the TSP in general, and the asset management process and capital expenditure plan in particular, demonstrate Hydro One's orientation around the following outcomes identified by the OEB in the RRF:

- **Customer Focus*:*** Services are provided in a manner that responds to identified customer preferences;

- **Operational Effectiveness***:* Continuous improvement in productivity and cost performance is achieved, and utilities deliver on system reliability and quality objectives;
- **Public Policy Responsiveness***:* Utilities deliver on obligations mandated by government (e.g., in legislation and in regulatory requirements imposed further to Ministerial directives to the Board); and
- **Financial Performance***:* Financial viability is maintained, and savings from operational effectiveness are sustainable.

1.1.5.3 OUTCOMES TO BE ACHIEVED

The key outcomes that Hydro One seeks to achieve through implementation of the asset management process and capital expenditure plan as set out in this TSP include, but are not limited to:

- **Customer Focus**: power quality improvements; improve customer reliability
- **Operational Effectiveness**: an injury-free workplace, minimized long-term costs to maintain the transmission system infrastructure and improve reliability, and restore top quartile reliability performance by mitigating risk arising from asset deterioration;
- **Public Policy Responsiveness**: continued compliance with regulatory requirements and applicable reliability standards; and
- **Financial Performance**: manageable and stable rate impacts over the course of the planning period.

The close alignment between the RRF outcomes and the outcomes that Hydro One seeks to achieve through implementation of this TSP is demonstrated from the following summary of the company's transmission business values and objectives, which is included in its 2019-2024 Transmission Business Plan and in TSP Section 1.5.

Customer Focus	**Customer Satisfaction**	• Improve current levels of customer satisfaction
	Customer Focus	• Engage with our customers consistently and proactively • Ensure our investment plan reflects our customers' needs and desired outcomes
Operational Effectiveness	**Cost Control**	• Actively control and lower costs through OM&A and capital efficiencies
	Safety	• Drive towards achieving an injury-free workplace
	Employee Engagement	• Achieve and maintain employee engagement
	System Reliability	• Provide top quartile reliability relative to transmission peers
Public Policy Responsiveness	**Public Policy Responsiveness**	• Ensure compliance with all codes, standards and regulations • Partner in the economic success of Ontario
	Environment	• Sustainably manage our environmental footprint
Financial Performance	**Financial Performance**	• Achieve the ROE allowed by the OEB

Figure 7 – Hydro One's Transmission Business Values and Objectives

1.1.5.4 (5.2.1 B) CUSTOMER ENGAGEMENT

Hydro One undertakes a broad range of ongoing customer engagement activities in connection with its transmission system and incorporates the feedback it receives from these activities directly into its investment planning process, both at the outset and throughout that process. Hydro One's understanding of its customer needs and preferences is derived largely from six sources, as follows.

The first source is the Large Customer Account Management Group. The Large Customer Account Management group provides a single point of contact for customers for all types of interactions other than real-time operations, operating events and outage planning. This group facilitates direct communications with transmission customers on a variety of matters including customer connection requests, sustainment and system development plans and projects, and concerns regarding service level or power quality. Communication with this group prior to the Investment Plan prioritization and optimization process enabled Hydro One to identify investments that were aligned with key customer priorities such as improving reliability and power quality. This aspect of the investment planning process is described in Section 1.3.

The second source is the OGCC's Customer Operating Support Group. The OGCC's Customer Operating Support Group has direct communications with transmission customers regarding real-time operations, the coordination of planned outages, responses to unexpected outages, and the coordination of switching activities. This group also organizes bi-annual customer meetings to coordinate outage planning and, on a weekly basis, sends individual customers reports of planned outages affecting their specific delivery point, as well as post-event investigation reports following unplanned outages. In addition, this group holds transmission-connected customer conferences to share information about Hydro One's plans for the year ahead. The key messages derived from customers through these efforts are shared with Hydro One's Large Customer Account Management group so as to help inform the ongoing tracking of customer needs and priorities.

The third source is a Large Customer Conference which is held annually for all of Hydro One's large transmission and large distribution customers. At the conference, customers are presented with information about significant Hydro One initiatives, upcoming technology changes, and other initiatives that might affect them. Specific sessions, including interactive panel discussions, are held during which Hydro One presents an overview of its upcoming investments and activities. Customers also have an opportunity to meet with and provide input and share concerns with Hydro One staff and members of the senior leadership team. Hydro One obtains initial indications about customer needs and preferences by soliciting input for the conference agenda. In addition, Hydro One's Planners attend the conference, meet directly with customers and receive a summary of feedback received through a post-conference survey.

The fourth source is a series of oversight committees established by Hydro One to actively track areas of high customer interest, where careful ongoing coordination of effort with other entities is valuable, and/or where coordinated health and safety oversight is of benefit. Committees include representatives from the various affected stakeholders and meet periodically. These are focused on Sarnia area reliability, OPG and Bruce Power switchyard oversight, Toronto Hydro, Hydro Ottawa, Metrolinx, Alectra project impacts and an LDC working group. Deliverables from these oversight committees provide Hydro One Planners with additional information to support investment candidate selection decisions.

The fifth source is customer satisfaction research. Hydro One obtains customer input by means of a formalized customer satisfaction research process that has been ongoing since 1999. All research is conducted by independent expert consumer research firms, most recently by Innovative Research Group ("IRG"), a third party research firm. Hydro One's Overall Customer Satisfaction was 90 per cent for 2018. Perhaps the most significant benefit of the survey is the comments provided by customers. These comments help Hydro One understand those areas which require investment focus over the planning cycle.

The final source is a customer survey. In anticipation of this Application, Hydro One undertook a Transmission Customer Engagement Survey to identify the needs and preferences of its transmission-connected customers. Content for the survey was the result of preliminary work performed by Hydro One to address lessons learned from the 2016 Transmission Customer Engagement effort, feedback received from intervenors in the last Transmission survey, and work performed with IRG. The objective was to craft a framework through which Hydro One could obtain information to guide its investment and business plans in an unbiased manner.

The Transmission Customer Engagement Survey was carried out on Hydro One's behalf by IRG. Customers participated in the survey through a customized website created and hosted by IRG to ensure that all data was collected in a private and secure manner. Hydro One and IRG made efforts to contact all Hydro One transmission customers to participate in this engagement, either by email, phone call or in-person. As indicated in the IRG Report, a copy of which is included in TSP Section 1.3.7, the results represent the opinions of the majority of customers as the survey response rate was 66%, or 103 of 153 customers. Response rates were 51% higher than those of the 2016 Transmission Customer Engagement that was reported on in Hydro One's last transmission rate filing (EB-2016-0160). In addition, a portion of the LDCs who participated in the survey based their input on the results of their own customer engagement activities so that feedback from LDC end-users is also reflected in the TSP. The resulting customer feedback indicated the following priorities:

- Safety, reliability, and outage restoration are Hydro One customers' top priority outcomes.
- All customer segments prefer to see investments spread out over time versus investing now with higher rates in short term and lower future increases or delaying investments with lower rates in the short term and higher future rates.
- Reducing the frequency of outages is more important than reducing the duration. However, the most important issue is to reduce the number of day-to-day interruptions.
- When presented with several investment scenarios, the majority of customers preferred investment levels in line with the investment plan that was before the OEB in the 2017 to 2018 proceeding[13] by at least a three to one margin. It is seen as

[13] The total 5 year capital investment plan associated with Scenario C was $6.6B from 2019-2023. The total 5 year capital investment plan included in the 2017-2018 transmission rate application was $6.1B.

reflective of the current approach which has served the system well, and a less risky option.

- About half of end-user participants (19 of 38) rate power quality as an "extremely important" outcome.

These preferences have been consistently reiterated in Hydro One's regular touch points with its customers, as described above in this section.

The Transmission Customer Engagement Survey was carried out sufficiently in advance of the present application so as to allow an opportunity for Hydro One management to hold a series of cross functional sessions to review the findings, trends and specific customer needs and preferences identified by the survey. In addition, processes were put in place to ensure that these needs and preferences, as well as those identified through Hydro One's other customer engagement initiatives, have been appropriately captured in the investment planning process to improve alignment between individual candidate investments identified by planners and the outcomes of the customer engagement activities. Feedback obtained through Hydro One's ongoing engagement initiatives since the survey are aligned with these results.

Through the incorporation of feedback received from the broad range of customer engagement activities into the TSP, Hydro One has been able to determine a funding envelope that balances its considerations of rate impacts, customer needs and preferences, as well as operational and compliance needs. These considerations are integral to the review and final approval of the Business Plan by Hydro One's Executive Leadership Team and its Board of Directors.

In addition, the enhancements made to Hydro One's customer engagement process are responsive to the concerns raised by the OEB in its Decision and Order on Hydro One's last transmission rate application (EB-2016-0160), issued on September 28, 2017 and revised November 1, 2017. In that decision, the OEB expressed concerns with certain aspects of the customer engagement process, particularly the need for Hydro One to (i) start its customer engagement process sufficiently in advance of filing its transmission rate application to allow for customer input to be incorporated in a meaningful way and to improve the level of participation, (ii) discuss with LDC customers practical ways to seek input from their end-users, and (iii) present information to customers in a manner that is unambiguous and easy to understand.

As noted, Hydro One's Transmission Customer Engagement Survey was carried out sufficiently in advance of this Application, which allowed an opportunity for a series of cross functional sessions within the company to review findings and ensure that identified needs and preferences have been appropriately captured in investment planning. To support the survey, Hydro One worked with IRG to develop clear materials through which Hydro One could obtain information to guide its investment and business plans in an unbiased manner. In addition, a portion of the LDCs who participated in the survey based their input on the results of their own customer engagement activities so that feedback from LDC end-users is also reflected in the TSP. In response to the OEB's finding that it should seek timely and meaningful input from First Nations and Métis representatives, please see TSP Section 1.3 and Exhibit A, Tab 7, Schedule 2 of the Application.

Moving forward, Hydro One is implementing a new Ongoing Customer Engagement Questionnaire that will quantify transmission customer's satisfaction regarding a number of reliability focused measurements. The questionnaire asks about customer satisfaction with Hydro One's current work program; satisfaction with outages, power quality, and reliability; investment priorities; unplanned outages mitigation and impact; and rate impacts. The results of this annual questionnaire will input directly into Hydro One's Customer Relationship Management system and will inform the planning process. Currently, directly connected transmission customers receive an annual reliability report which summarizes performance at transmission and distribution delivery points. The report summarizes the number of Delivery Point Interruptions each customer has every year, on both the transmission and distribution system. The reliability report will allow customers to provide more informed input into customer engagement, such as Hydro One's new Ongoing Customer Engagement Questionnaire.

1.1.5.5 (5.2.1 A) REGIONAL PLANNING

The policy framework for regional planning and the extent to which it affects investment planning for Hydro One's transmission system is described in greater detail in TSP Section 1.2. The RRF requires that infrastructure planning be undertaken on a regional basis to ensure that regional issues and requirements are integrated into a utility's planning processes. As indicated, Hydro One participated in working groups comprised of representatives from the IESO, LDCs and other stakeholder groups for 19 of the 21 regions across the province where Hydro One is the lead transmitter. Hydro One's participation in these regional planning initiatives led to the identification of over 60 transmission investments, with 46 investments totalling approximately $1.4 billion in gross capital expenditures, which Hydro One proposes to implement and bring into service during the 2020 to 2024 planning period. The remaining 14 projects are planned to go in-service outside of the planning period. The number of projects by Group and Region are identified in Table 4 below, with further details on each of the projects set out in Section 1.2.

Table 4 – Number of Projects Identified in Regional Planning by Group and Region Planned for In Service between 2020-2024

Group	Region	Number of Projects
1	Burlington to Nanticoke	7
	Greater Ottawa	8
	GTA West	2
	Kitchener-Waterloo-Cambridge-Guelph	3
	Metro Toronto	12
	Northwest Ontario	1
	Windsor-Essex	6
2	London Area	2
	South Georgian Bay/Muskoka	4
3	Chatham/Lambton/Sarnia	1
	Total	**46**

1.1.5.6 (5.2.1 F) TRANSMISSION PLANNING PROCESS

Hydro One's Transmission Planning Process is comprised of a comprehensive and sophisticated process for managing its extensive transmission system assets and prudently planning its transmission investments. This process takes into account, and strives to produce, outcomes that are consistent with those identified in the RRF and that include the specific outcomes, identified through customer engagement, as described above and in TSP Section 1.3. The components of the process are set out in Figure 8 below.

Figure 8 – Hydro One's Transmission Planning Process

The core aspect of Hydro One's Transmission Planning Process is its Capital Planning Process. The Capital Planning Process refers to those aspects of the Transmission

Planning Process that involve identifying, developing and scoping investment candidates, prioritizing the portfolio of investment candidates based on risk, culminating with executive approval of a specific capital plan. Within the broader context of the Transmission Planning Process, the Capital Planning Process is informed by Hydro One's investment planning context, which includes Hydro One's strategic vision, planning and other relevant economic assumptions, customer engagement feedback, delivery of key outcomes, and overall assessment of the needs of Hydro One's assets, customers and other stakeholders.

Hydro One's Capital Planning Process consists of two interrelated functions. The first is a thorough and ongoing asset management process that involves monitoring and reviewing transmission assets and assessing their condition, assessing system and customer requirements through the regional planning process and customer connection process, as well as identifying and scoping investment candidates ("Asset Management"). This is followed by a risk-based investment planning process through which investment candidates are reviewed, prioritized and narrowed into an achievable set of planned investments in specific programs and projects that help drive Hydro One towards achieving its intended outcomes ("Investment Planning").

In its Decision and Order in Hydro One's last transmission rate proceeding (EB-2016-0160), the OEB required Hydro One to complete an independent third-party assessment of its TSP, including an assessment of its asset condition assessment and capital investment planning processes. Hydro One engaged Metsco Energy Solutions to review its asset condition assessment process and the Boston Consulting Group to review its capital investment planning process. The Metsco Energy Solutions and Boston Consulting Group reports are discussed and provided in TSP Section 1.4. Generally, Metsco Energy Solutions found that both the Asset Risk Assessment and Asset Analytics align with other asset management frameworks found elsewhere in the industry and are sufficiently rigorous and robust to accomplish their intended tasks from an analytical perspective. The Boston Consulting Group found that Hydro One has implemented a consistent and thorough capital investment planning process that meets or exceeds expectations for an above average utility planning process in all aspects.

Hydro One's Capital Expenditure Plan, as set out in Section 3 of this TSP, itemizes the specific programs and projects that have received executive approval for implementation through the Capital Planning Process. Hydro One's Asset Management and Investment Planning processes are summarized below and are discussed in greater detail in Section 2.

Asset Management

Hydro One's Asset Management process draws upon the company's deep expertise in a variety of disciplines - management, financial, economic, engineering, operations – to monitor its transmission system assets, identify and define needs, and determine the optimal timing for executing maintenance work and capital investments throughout the asset lifecycle. In carrying out this responsibility, Hydro One strives to ensure that it delivers, and can continue to deliver over the long-term, a level of transmission service that is responsive to identified customer needs and preferences, as well as operational needs, while managing risks and mitigating rate impacts.

The Asset Management process encompasses the initial stages of Hydro One's Capital Planning Process. During this process, Hydro One undertakes extensive and detailed technical reviews of its assets to identify a set of investment candidates. Investment candidates are potential programs and projects that are put forth for further consideration during the Investment Planning process, which is discussed in the next section.

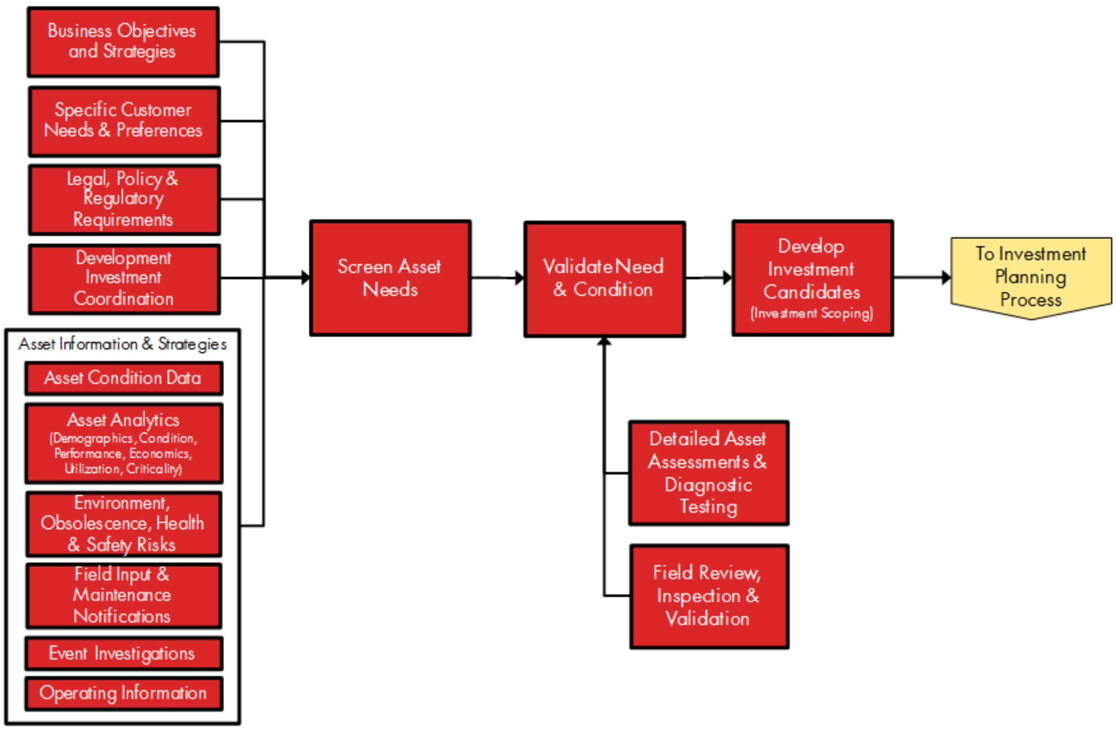

Figure 9 – Hydro One's Capital Planning Process – Asset Risk Assessment

Hydro One's Asset Management process starts with a thorough and systematic review of its transmission asset investment needs, which is reflected in Figure 9 – Hydro One's Capital Planning Process – Asset Risk Assessment. The needs assessment identifies and evaluates individual asset needs that drive the development of candidate investments and includes the collection of data which enables risk scoring to support prioritization and optimization of work undertaken later in the Investment Planning Process. The needs assessment considers (i) asset needs, (ii) customer needs and preferences, (iii) system needs (including those identified through participation in regional planning), and (iv) other external influences. The needs assessment also identifies potential hazards, vulnerabilities, threats or other risk sources that could present obstacles to achieving Hydro One's business objectives.

Hydro One carries out a continuous asset risk assessment ("ARA") process to determine individual asset needs which rely on asset condition data, engineering analysis and other information including the input of experienced planning professionals. An asset analytics system enables Hydro One planners to review aggregated information from various enterprise reporting systems. This drives efficient and effective planning decisions by ensuring a consistent view of asset information for all planners. The information contained within the asset analytics system includes condition information driven by deficiency and preventative maintenance reports, demographic information (including make, model, type and criticality to the transmission system), performance data based on equipment outages, utilization information, and economics. The asset analytics system combines information from various Hydro One databases to provide a common understanding of asset health and aids Hydro One planners in identifying asset risk and optimizing asset lifecycles. Hydro One's planners also take into account additional factors such as load forecasts, equipment ratings, operating restrictions, security incidents, environmental risks and requirements, compliance obligations, equipment defects, obsolescence, and health and safety considerations to ensure capital expenditures target the most appropriate mix of assets.

The ARA process is primarily concerned with the major equipment groups that directly affect system reliability, namely transformers, conductors, breakers and protection and control systems and evaluates them on the following six risk factors:

- Condition - Risk related to the increased probability of failure that assets experience when their condition degrades over time.
- Demographics - Risk related to the increased probability of failure exhibited by assets of a particular make, manufacturer, and/or vintage.
- Criticality - Represents the impact that the failure of a specific asset would have on the transmission system
- Performance - Risk that reflects the historical performance of an asset, derived from the frequency and duration of outages

- Utilization - Risk that reflects the increased rate of deterioration exhibited by an asset that is highly utilized
- Economics - Risk based on the economic evaluation of the ongoing costs associated with the operation of an asset

When assessing individual asset needs, Hydro One's Planners engage in a process of grouping identified needs into logical, functional and geographic groups. For example, a customer need for increased capacity and an asset need to replace transmission station equipment, such as a transformer or switchgear, might be grouped together if the same transmission station is involved. Through this process, diverse individual needs are brought together to form potential projects or programs that may be brought forward as candidate investments. These groupings of potential candidate investments are then scoped and defined based on identified asset needs, customer feedback and other inputs. Following this, Hydro One undertakes a further validation process, described below, to confirm that the need for the project or program is still there, has not evolved and will not be addressed by other means.

As part of investment development, on-site assessments are conducted to ensure site-specific factors such as the physical design, clearances, constructability and safety options requiring geographic flexibility, etc. are considered. During these on-site assessments, planners and field personnel validate and confirm asset condition and related information identified through enterprise reporting systems and asset analytics. Planners will also speak directly with Hydro One personnel who are involved in the day-to-day management and maintenance of the equipment in order to get additional insights into deficiencies and asset needs.

For high-value assets, such as transformers, Hydro One's subject matter experts perform a thorough analysis and advise on issues such as equipment obsolescence, manufacturer support and conduct "repair vs. replace" evaluations. All transformer replacements require review by subject matter experts who prepare Transformer Assessment Reports that are used to validate investment decisions.

These steps inform the development of a set of potential candidate investments. Hydro One's capital investment plans and potential candidate investments are then reviewed with internal stakeholders, such as the company's Customer Service and Transmission and Stations work delivery functions, as well as affected customers. Through this review process, Hydro One ensures that identified customer needs and preferences have been considered and used to inform the development of investment plans and specific candidate investments. Where more than one feasible alternative has been identified for meeting the identified need, a financial analysis (i.e. Net Present Value) is conducted to assist in determining the preferred alternative to put forward as a candidate investment.

The result of the aforementioned ARA process is that a portfolio of specific candidate investments is submitted for further consideration through the Investment Planning process. In that process, specific investments are prioritized to align with intended outcomes based on corporate priorities and strategic objectives, regulatory requirements, investment risks and identified constraints. Before describing the Investment Planning process, the following sections highlight some of the characteristics of asset management relating specifically to each of the main classes of transmission assets – stations and lines.

Stations Asset Management

As noted, Hydro One's transmission system includes 294 stations. Prior to 2014, Hydro One's approach to station asset management was asset-specific. Separate programs were used to consider, plan for and implement replacements for particular asset types (i.e. transformers, breakers and switches) across the province. In 2014, Hydro One transitioned to an integrated approach to station asset management to enable successful delivery of the work program in an efficient manner that minimizes customer impact by requiring fewer planned outages, and optimizing design, execution and operating efficiency. The integrated approach enables work that is required at a particular station to be bundled together and executed at once. Integration of station work and the timing for this work is oriented around key station assets (i.e. transformers, breakers, switches and protection and control equipment).

This station-focused approach addresses infrastructure that is aging and in poor condition, and integrates OM&A and capital programs across multiple disciplines. Hydro One has established a recurring 7-10 year assessment cycle that enables all necessary renewal work to be performed at each of the 294 transmission stations during the cycle. This ensures that asset needs at all stations are reviewed on a recurring basis, which may or may not result in the need for investment after applying the ARA process. By developing and implementing integrated investments for each station, this approach enables Hydro One to efficiently use outages and to minimize the total number of outages required to complete necessary renewal work. The candidate investments identified through the Asset Management process include station-specific packages of work that have been developed in accordance with the established assessment cycle.

Lines Asset Management

Hydro One's approach to asset management for its transmission line assets is shaped by the nature of the specific line assets and their typical service lives. In particular, transmission conductors have an expected service life of 90 years. When a conductor fails or based on its condition, as confirmed by testing, has been determined to have reached end of life, replacement is the only solution. When the conductor needs replacement, this creates a rare opportunity in the asset lifecycle for Hydro One to implement a full line refurbishment of the relevant segment in order to bring the associated assets to a condition that is as close to new as possible. This includes poles, parts of steel structures, foundations and the conductors. Upon completion of a full line refurbishment, the line will be ready to return to service for another 90 years. Other transmission line components do not last this long and are therefore the subject of separate, recurring, asset replacement programs. Such programs are in place for assets such as wood poles, insulators, shield wire, aviation lighting and U-bolts. Program budgets are established through the investment planning process and are typically based on unit costs and the numbers of units that require replacement in a given year. Regardless of the type of transmission line asset, Hydro One's approach to Asset Management is condition-driven such that assets are not replaced unless their condition warrants it.

Investment Planning

Since the EB-2016-0160 proceeding, Hydro One has implemented several changes that address investment planning process concerns raised by intervenors and the OEB. These are summarized in Table 1 above and elaborated on as follows.

In response to concerns raised during the EB-2016-0160 proceeding, Hydro One has implemented an improved eight-step investment planning process. Key improvements to the investment planning process include:

- Consistent scoring for safety, reliability and environmental risk mitigation based on new standardized frameworks;
- Clear definitions of risk impacts to enable consistent scoring across investment types, and calibration sessions to ensure standardized scoring practices; and

Challenge sessions, which are facilitated sessions held with a broad set of stakeholders to (i) review the prioritized portfolio, (ii) confirm non-risk considerations including productivity, (iii) discuss investments on the margin, and (iv) make trade-offs

This process is designed to provide a consistent and common understanding and prioritization and optimization of risk to cost effectively deliver the highest value for Hydro One and its customers. This allows candidate investments to be consistently assessed and prioritized based on level of risk mitigated, cost and value delivered on achieving business objectives.

The process generates an annual budget for work program Operations, Maintenance and Administration ("OM&A") and capital investments, and a six-year planning forecast that allows Hydro One to meet the OEB's filing requirements for a consolidated five-year capital plan.

In summary, the investment planning process consists of the following steps:

1. Investment Planning Context: Hydro One draws on multiple sources of input in the development and prioritization and optimization of the investment plan consistent with Hydro One's Strategic Business Objectives and the OEB's RRF. The investment plan is guided by: (i) strategic vision, (ii) planning and other relevant economic assumptions, (iii) customer engagement feedback, (iv) delivery of key outcomes, and (v) overall assessment of the needs of Hydro One's assets, customers and other stakeholders;
2. Candidate Investment Development: Through the Asset Management process described above, candidate investments are identified, developed and submitted for inclusion in the investment plan;
3. Investment Assessment and Calibration: Investments are scored for safety, reliability, and environmental risk mitigation using a clear and consistent scale based on risk taxonomies. Special, non-risk considerations are also flagged (e.g. Strategic, compliance, customer needs and preferences). Once candidate investments have been scored and flagged, the scores are reviewed in facilitated discussions among investment owners in calibration sessions.
4. Prioritization and Optimization: The results of the risk assessment are translated into risk scores, which are used to generate an initial prioritization and optimization of investments. Following the initial prioritization and optimization, facilitated challenge sessions are held with a broad set of stakeholders to (i) review the prioritized portfolio, (ii) confirm non-risk considerations including productivity, (iii) discuss investments on the margin, and (iv) make trade-offs,

5. Enterprise Engagement: Executing lines of business review the investment plan for operational/execution feasibility, strategic alignment and to challenge investment needs and assumptions;
6. Develop Final Plan: Final decisions are made to arrive at a final version of the investment plan and its outcomes against strategic, customer, and risk considerations;
7. Review and Approval: The investment plan and associated outcomes are reviewed and approved by VPs, the Executive Leadership Team, and the Hydro One Board; and
8. Execution and Performance Monitoring: The execution of the plan is monitored to ensure it is delivered as efficiently as possible.

The Investment Planning process is described in greater detail in Section 2.1 of this TSP.

1.1.5.7 (5.2.1 A) CAPITAL EXPENDITURE PLAN

Based on Hydro One's assessment of its transmission system, a significant portion of its assets have deteriorated to the point where they pose a risk to achieving business objectives for safety, reliability, environment and the customer. Therefore, over the planning period, Hydro One plans to spend approximately $6.6 billion in capital; representing a compound annual growth of 3.5% over five years, to maintain transmission reliability performance, address customer needs and preferences, and mitigate asset and operational risks. This includes delivering $590 million of capital productivity savings improvements (related to the work program) through information technology, procurement, and process efficiency improvements in executing the work.

Hydro One's capital expenditure forecast is $1.2 billion for 2020, increasing to $1.4 billion in 2024. These investments, reflected in Hydro One's TSP, are grouped into four categories: System Access, System Renewal, System Service, and General Plant. Approximately 83% of Hydro One's transmission capital plan is focused on System

Renewal investments. Tables 5 and 6 summarize the capital investment plan based on these four investment categories along with the Progressive Productivity Placeholder savings and Directive Adjustment that are applied as a reduction to the capital expenditures that are sought for rate recovery. Progressive Productivity Placeholder savings are explained further below.

Table 5 – 2020 – 2024 Capital Spending Forecast ($ Million)

Category	Forecast (Planned $M)				
	2020	**2021**	**2022**	**2023**	**2024**
System Access	24.8	11.3	11.7	12.7	4.1
System Renewal	865.2	1,103.1	1,172.8	1,177.4	1,193.8
System Service	204.1	148.2	151.8	174.3	204.2
General Plant	115.4	94.4	94.7	83.6	58.9
Progressive Productivity Placeholder	(17.0)	(39.0)	(61.0)	(78.0)	(91.0)
Directive Adjustment[14]	(0.3)	(0.3)	(0.4)	(0.4)	(0.4)
Total	**1,192.2**	**1,317.7**	**1,369.6**	**1,369.6**	**1,369.6**
System OM&A[15, 16]	**375.8**	*	*	**N/A**	**N/A**

Table 6 – 2020 – 2024 Capital Spending Forecast (% by Category)

Category	2020	2021	2022	2023	2024
System Access	2.1%	0.9%	0.9%	0.9%	0.3%
System Renewal	72.6%	83.7%	85.6%	85.9%	87.1%
System Service	17.1%	11.2%	11.1%	12.7%	14.9%
General Plant	9.7%	7.2%	6.9%	6.1%	4.3%
Progressive Productivity Placeholder	-1.4%	-3.0%	-4.5%	-5.7%	-6.6%
Directive Adjustment	0.0%	0.0%	0.0%	0.0%	0.0%

Investment Summary Documents ("ISD") detailing the specifics for each material investment with spending greater than $3M in any one year are listed in Section 3.3. An

[14] The Directive Adjustment reflects the impact of the directive issued by Ontario's Management Board of Cabinet on February 21, 2019 and the associated compensation framework they approved on March 7, 2019. Refer to Exhibit F, Tab 4, Schedule 1 for further details.
[15] System OM&A includes Operations, Maintenance and Administration expenses. System OM&A for 2021 to 2022 is determined based on the escalation factor identified in Exhibit A, Tab 4, Schedule 1
[16] Includes the Directive Adjustment described in Exhibit F, Tab 1, Schedule 1.

overview of the main factors driving the investments in each of these categories is set out below.

System Renewal

Hydro One's TSP reflects the need for continued station renewal investments at a cost of $3.5 billion, or approximately 53% of the total planned capital expenditures over the planning period, to address deteriorated station assets including transformers, circuit breakers, protection, control and telecom equipment. These replacements are expected to approximately maintain the proportion of transformers on the system that are beyond their expected service life at 26%, approximately maintain the proportion of protection systems operating beyond their expected service life at 28% and maintain the number of breakers that are beyond their expected service life at 12%. This includes the replacement of 72% of the air-blast circuit breakers (ABCBs) at a cost of $594M. ABCBs are about 10 times more expensive to maintain and about 4 times less reliable than their equivalent SF6 circuit breakers.

The TSP also delivers an increased emphasis on line renewal investments at a cost of approximately $2.0 billion to refurbish and replace end of life transmission lines, underground cables, insulators, and wood poles while continuing with tower coating of steel structures to extend their useful life, but at a reduced pacing consistent with prior direction from the OEB. While the planned rate of refurbishment does not keep pace with the overhead lines demographics, the risk is managed through the use of detailed conductor assessments to identify poor condition conductors, informing the line refurbishment program. Lines are candidates for conductor condition assessment starting at 50 years of age.

In developing the TSP, Hydro One recognized that execution of the plan will take place in the context of the broader Ontario power system. In determining the timing and pacing of its investments, Hydro One considered both its own ability to execute capital and

OM&A work efficiently and its ability to secure planned outage time to minimize impacts on customers and other stakeholders in Ontario. As a result, it has planned the pace of renewal work so that certain critical work to reduce risk on the system could be completed in the next five years to ensure that transmission assets are in service and not subject to increased outage constraints resulting from increased failures or additional maintenance that would make the work more difficult to complete.

These investments are required to address the significant demographic pressure that Hydro One is experiencing for some key asset classes. Figure 10 shows the forecasted cumulative number of assets that will exceed their expected service life during the 2019 to 2029 period in the absence of any planned or unplanned replacements. Over this period, the number of assets that are beyond the expected service life in these asset classes would increase by 1.8 to 3.6 times current levels. This rapid and growing shift poses inherent operating and resourcing risks that Hydro One is planning for by proactively and strategically pacing its investments in order to limit pressure on both OM&A and capital costs, while providing the level of service and reliability that customers expect.

	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029

Figure 10 – Number of Assets Beyond End of Service Life Per Year Summary

System Access and System Service

The TSP funds $947 million of System Access and System Service capital that is required over the planning period to provide transmission access and additional capacity for new customer connections and to implement regional development plans that were developed jointly with customers, transmitters, distributors and the IESO. These investments will result in the addition of seven new transformer stations, ten customer-owned stations and 272 circuit km of new or upgraded transmission lines. Major projects include the development work for the North-West Bulk transmission expansion, new transmission switching and lines facilities to support load growth in the Leamington area, transformation and lines at Milton Switching station, and upgrades/expansion in Barrie and Toronto areas.

General Plant

This TSP funds $447 million of general plant capital that is required over the planning period to support day-to-day business and operations activities such as buildings, tools, equipment, rolling stock, as well as information technology hardware and software. This includes investing $189 million in operating infrastructure and control facilities. This amount includes the new Integrated System Operating Centre ("ISOC"), which represents an investment of $45 million over the planning period, as well as an upgrade to Hydro One's Network Management System – used for grid control, and a refresh of Hydro One's integrated voice communication telephony system.

1.1.5.8 (5.2.1 C) SOURCES OF COST SAVINGS

In its Decision and Order in EB-2016-0160, the OEB directed Hydro One to establish firm short and long-term targets for productivity improvements and associated reductions in revenue requirements as a means to drive continuous improvement and improve the company's internal and external benchmarking standings. As a result of its efforts to address those expectations, and to further its commitment to delivering outcomes that are valued by its customers, Hydro One has developed a comprehensive and rigorous process for identifying, developing, implementing, monitoring and measuring productivity initiatives that will reduce costs while maintaining or improving service quality and work outputs. Hydro One's commitment to achieving incremental and continuous productivity improvements is central to the planning and execution of work programs across the company. Within this framework, quantifiable productivity improvements are included in the Business Plan and corporate scorecards with clear accountabilities for delivering the anticipated savings.

Using this approach, Hydro One has identified savings opportunities in Capital and OM&A totaling approximately $704 million over the plan period. All of these savings are net savings with a direct correlation to a budget and/or spending forecast reduction. Underlying these savings are specific productivity initiatives that have been identified, reviewed, approved and made subject to tracking and reporting requirements. Hydro One has identified savings opportunities totalling approximately $704 million over the 2020-2024 TSP period. There are $353 million in capital productivity savings, $114 million in OM&A productivity savings and $237 million in undefined capital savings. This latter category of savings falls within "Progressive Productivity". Progressive Productivity is a further reduction in cost that Hydro One has included in the final Transmission Business Plan in response to concerns that were raised in the OEB's decision in the Prior Proceeding regarding the level of investment. It represents a commitment from Hydro One to find further efficiencies over the planning period when executing the necessary planned investments in its transmission system without reducing work volumes. Progressive Productivity savings total $286 million over the planning period and are included in the Transmission Business Plan in the form of:

1. $49 million in Progressive Operations (Defined Capital) savings associated with initiatives that have been identified but which have not yet been proven and verified through the productivity governance framework; and
2. $237 million in Progressive Operations (Undefined Capital) savings which are included as placeholder in the Business Plan to be allocated to any future initiatives that have not yet been identified.

Approximately $590 million of the identified savings opportunities are related to Operations (Operations OM&A, Operations Capital, Progressive Operations (Defined Capital) and Progressive Operations (Undefined Capital), approximately $44 million in savings are IT-related (OM&A and Capital) and approximately $70M in savings are related to Corporate Initiatives (OM&A and Capital). Further details can be found in TSP Section 1.6

Hydro One expects to achieve these significant cost savings over the forecast period through good planning and effective execution of the TSP. Hydro One's productivity framework is further described in Section 1.6 and the productivity savings that Hydro

One expects to achieve over the 2020 to 2024 forecast period are summarized in Table 7 below.

Table 7 – Productivity Savings Forecast ($Millions)

** "Transmission" refers to Chapter 2 of the OEB's Filing Requirements for Electricity Transmission Applications (February 11, 2016).*

1.2 (5.2.2) COORDINATION THROUGH REGIONAL PLANNING

Planning transmission infrastructure with key stakeholders in a regional context promotes transparency and the cost-effective development of electricity infrastructure in Ontario. This is one of the key guiding principles in the Board's Renewed Regulatory Framework ("RRF"), which states that infrastructure planning on a regional basis, between licensed transmitters and distributors, is to be undertaken to ensure that regional issues and requirements are integrated into a utility's planning processes.

Hydro One Transmission is actively involved in the regional planning process and leading the development of Needs Assessments and Regional Infrastructure Plans. This is consistent with Hydro One's business objective of safely delivering a cost effective and reliable supply of electricity to meet its customers' needs.

This Exhibit provides an overview of the regional planning process and associated customer consultation processes used to engage distributors and other customer groups in regional planning activities. This Exhibit also provides a status update on each of the regions, highlighting investments arising from the regional planning, which form part of Hydro One's capital plan. Hydro One's capital plans are described in TSP Section 3.3.

1.2.1 (5.2.2) OVERVIEW OF THE REGIONAL PLANNING PROCESS

As described in the *Planning Process Working Group Report to the Board: The Process for Regional Infrastructure Planning in Ontario* (the "PPWG Report"), planning for the electricity system in Ontario is generally conducted at three levels:

1. Bulk system planning;
2. Regional system planning; and,
3. Distribution system planning.

Regional planning addresses supply and reliability issues at a regional and/or localized level, such as the supply facilities that connect and deliver power to a group of load stations in an area or region. Regional planning generally considers the 115kV and 230kV portions of the power system, that supply various parts of the province but can overlap with bulk system planning and/or distribution system planning at the interface points or where there may be regional resource options or distribution solutions to address the broader local area for the specific region.

Figure 1 illustrates the various phases of the regional planning process, as documented in the PPWG Report. Hydro One adheres to this process and the corresponding requirements under the Transmission System Code and Distribution System Code, as applicable.

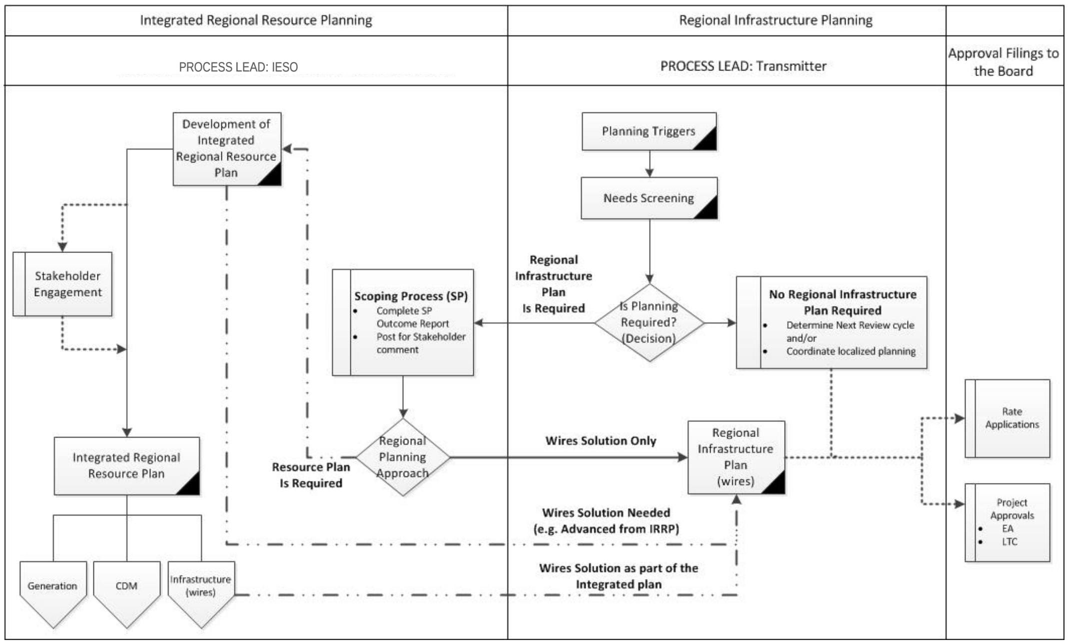

Figure 1: Regional Planning Process

The regional planning process is initiated by a planning trigger. Potential triggers include regularly scheduled Needs Screening by the transmitter, a scheduled review specified in an existing Regional Infrastructure Plan, a Government directive, a significant change to a code or standard, or an emergent need brought forward by the transmitter, distributors, customers, or the Independent Electricity System Operator ("IESO") that must be addressed before the next scheduled review. It is intended that this process is to be repeated for each of the planning regions identified in the PPWG Report every five years; though the process may be more frequent depending upon the emergence of new needs.

Once the regional planning process is initiated by a planning trigger, the process unfolds through the following phases:

- Needs Screening (hereinafter referred to as Needs Assessment ("NA"))[1];

[1] The Needs Screening and Scoping Process phases of regional planning are as described in the PPWG Report; whereas Hydro One refers to these as the Needs Assessment and Scoping Assessment in accordance with the terminology used in the Transmission System Code.

- Scoping Process (hereinafter referred to as Scoping Assessment ("SA"))[1];
- Integrated Regional Resource Plan ("IRRP"); and
- Regional Infrastructure Plan ("RIP").

Needs Assessment

The NA, for a given region, is led by the lead transmitter in the region in consultation with the subject matter experts from the local distributors ("LDCs") and the IESO. These representatives are referred to as a "Study Team"[2]. In this phase, the Study Team identifies merging needs, and undertakes an assessment to determine potential alternatives or solutions to address the needs. During the assessment, information regarding transmission assets reaching the end of their useful life is also identified and assessed for right sizing the equipment. In cases where: (a) the needs are local in nature; (b) further review by subsequent phases in the regional planning process is not required; and (c) the needs can be addressed directly by the transmitter and local distributor(s) or other transmission connected customer(s) through transmission and/or distribution facilities (i.e., a "wires" solution), a local plan is developed. The local plan is ultimately incorporated in the RIP for the region.

Scoping Assessment

In circumstances where the Study Team considers further planning studies and coordination to be necessary, the IESO initiates the SA phase. In this phase the IESO, in collaboration with the lead transmitter and impacted LDCs, reviews the information collected during the NA phase. The IESO also considers information related to potential non-wires alternatives, and determines the most appropriate regional planning approach, i.e., whether an IRRP or a RIP, or both, is required to address the needs in the region or sub-region.

---

[2] The *Working Group* as described in the PPWG report is equivalent to *Study Team* as referred to by Hydro One and is the current terminology utilized in the RIP reports.

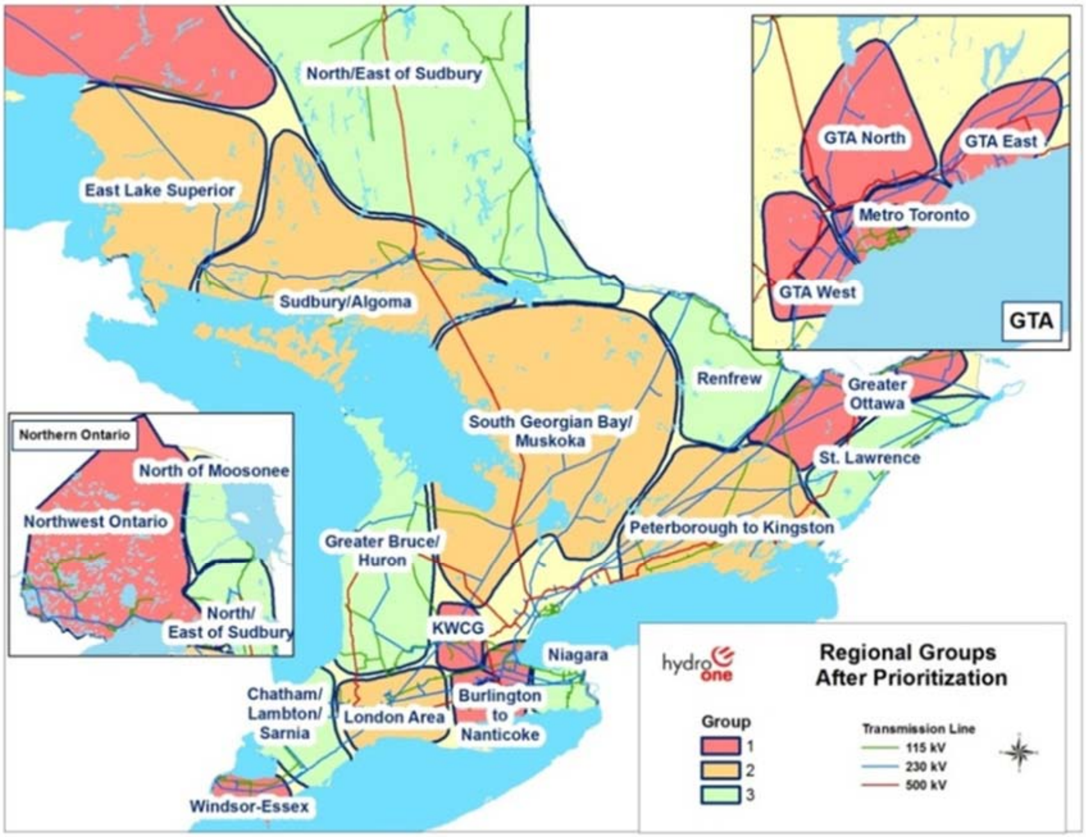
Integrated Regional Resource Plan

The IRRP process involves identifying, evaluating and integrating potential wires and non-wires solutions at the regional or sub-regional level. The IRRP phase generally assesses resource (i.e., generation and/or conservation and demand management) versus wires infrastructure options at a higher level, but with sufficient detail to allow for a comparison of options. If during this phase it is determined that resource options are best suited to meet a need, then those options are further planned by the IESO. However, if wires options are the more appropriate alternative, then those options are further assessed and/or planned as part of the RIP process.

Regional Infrastructure Plan

The RIP process is the final phase of the regional planning process and involves confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle (including end-of-life transmission asset needs that may influence a solution to address broader regional needs); and development of a wires plan to address the needs. This phase is led and coordinated by the transmitter, and the deliverable from this phase is a comprehensive report setting out a wires plan from a regional planning perspective. The wires plan may include distribution investments or options affecting regional needs for optimal outcomes. The recommendations related to transmission and distribution wires planning stemming from the NA, SA, and IRRP are part of the RIP report for the region. The status and corresponding documents from each phase are published on the Hydro One and/or the IESO regional planning websites.

As outlined in Figure 2, there have been 21 electrical regions defined for the purposes of implementing regional planning in Ontario. Each of the 21 regions has been assigned to one of the three regional planning groups in order to prioritize and efficiently manage the regional planning process. Hydro One Transmission is the lead transmitter in all regions, except East Lake Superior and North of Moosonee. The first full cycle of the regional planning for all three groups, which took place over a period of approximately four years, was completed in August 2017 and the second cycle is now in progress commencing with Group 1.



Group 1	Group 2	Group 3
1. Burlington to Nanticoke 2. Greater Ottawa 3. GTA East (1) 4. GTA North 5. GTA West 6. KWCG (2) 7. Metro Toronto 8. Northwest Ontario 9. Windsor-Essex	1. East Lake Superior (3) 2. London Area 3. Peterborough to Kingston 4. South Georgian Bay/Muskoka 5. Sudbury/Algoma	1. Chatham/Lambton/Sarnia 2. Greater Bruce/Huron 3. Niagara 4. North of Moosonee (3) 5. North/East of Sudbury 6. Renfrew 7. St. Lawrence

Notes: *(1) Subsequent to the PPWG Report, GTA East was moved from Group 2 to Group 1*
(2)"KWCG" stands for Kitchener-Waterloo-Cambridge-Guelph
(3) Hydro One Transmission is not the lead transmitter in this region

Figure 2: Regional Planning Regions

1.2.2 (5.2.2 A) REGIONAL PLANNING CONSULTATIONS

As part of the regional planning process, Hydro One undertakes extensive consultation with the LDCs and the IESO to identify needs and develop plans as envisioned by the Board in its RRF. Hydro One also reaches out to its large transmission-connected customers to obtain and update their future plans and electricity load forecasts.

Study Teams have been established in all of the 19 regions across the province, where Hydro One Transmission is the lead transmitter, in order to undertake regional planning. Approximately 70 LDCs along with the IESO participated during the first cycle and continue to be active in the second cycle of the regional planning process. In the Northwest Ontario region, the Study Team led by the IESO also sought input from other stakeholder groups such as: Northwestern Ontario Municipal Association, Common Voice, Ontario Mining Association and municipalities. This unique approach was required due to the vast geographic area, uncertainties related to changing resources and industrial/mining load and challenges not normally seen in other parts of the province.

At each phase of the regional planning process, and for each of the regions, Hydro One has undertaken a combination of the following consultation activities to ensure the involvement and engagement of Study Team members:

1. **Pre-meeting Conference Calls/Webinars:** At the beginning of each phase, LDCs and the IESO are notified in advance of upcoming regional planning activities and are provided an overview of the process.

2. **Kick-off Meetings/Conference Calls/Webinars:** Kick-off meetings with the Study Team are organized to initiate each of the phases of the regional planning process and provide templates for the collection of information/data.

3. **Additional Face to Face Meetings/Conference Calls/Webinars:** The Study Team meets on a regular basis to discuss planning matters, such as: assessment methodology, customer needs, and regional needs and timing before recommending a preferred solution.

In addition to the Study Team members, other customers and stakeholders, such as local municipalities, indigenous communities, business groups, citizen groups, consumers and environmental and conservation groups are contacted and have an opportunity to provide input as part of the IESO-led engagement during the SA and IRRP phases. If continued community input and broader engagement is needed for the regional planning, then a Local Advisory Committee ("LAC") made up of representatives from public and various interested customer and stakeholder groups is formed. In areas where there are a large number of First Nations communities, a First Nations local advisory committee may also be established and representatives from this committee would then be appointed as members of the regional LAC.

The LAC is an advisory body and a forum for communities to provide their input and stay informed about regional planning activities within their region. As an advisory body, the LAC members represent communities and bring forward their interests within the study area and provide insight into their values and perspectives. The LAC input is amongst many inputs that are considered by the Study Team, including information on local priorities (such as municipal or community energy plans), when developing options identified in the plan and ideas on the design of community engagement strategies.

Currently, there are ten active LACs that have been formed to engage communities in the regional planning process, as indicated below:

- Three in the Northwest Ontario region to represent three of the sub-regions: Greenstone-Marathon, City of Thunder Bay, and West of Thunder Bay;

- Two in the South Georgian Bay / Muskoka region to represent the two sub-regions: Parry Sound / Muskoka, and Barrie / Innisfil;
- One in the GTA North region to represent the York sub-region; and
- Four to represent the following four regions: GTA East, Greater Ottawa, Metro Toronto, and Windsor-Essex.

Hydro One also undertakes a broader and comprehensive engagement with the public and other stakeholders at the project development level. All major transmission projects go through the environmental assessment process in accordance with the *Ontario Environmental Assessment Act* and/or the leave to construct approval process in accordance with Section 92 of the *Ontario Energy Board Act*. Each of these processes requires extensive public and stakeholder consultation on projects through such methods as meetings, presentations, public information centres, notices and newspaper advertisements.

In addition to the publication of regional planning reports on Hydro One's website, these consultations ensure transparency in regional planning activities that may influence stakeholders' local plans (such as municipal planning or the development of community energy plans) and they demonstrate Hydro One's responsiveness to public policy and commitment to being a vital partner in the continued economic success of the province.

For specific information on the participants involved in the planning process for particular regions, please refer to the regional planning reports filed as Attachments to this Exhibit or to Hydro One's Regional Planning website, noted below.

https://www.hydroone.com/about/corporate-information/regional-plans

1.2.3 (5.2.2 B) REGIONAL PLANNING OUTCOMES AND STATUS UPDATE

As the lead transmitter, Hydro One Transmission leads the NA and RIP phases of the regional planning process, and actively participates in the SA and IRRP phases led by the IESO.

Hydro One is required, by Section 3C.3.3 of the Transmission System Code, to submit a report to the Board annually on the status of the regional planning activities for all regions. Hydro One filed its 2018 Status Report with the Board on November 1, 2018.[3] As explained in the 2018 Status Report, Hydro One continues to make progress on the second cycle of the regional planning process; including several enhancements that will be reflected in the RIP reports. Table 1 below provides a summary of the current status for each region and sub-region showing the planning phases that are underway or completed. The Sections that follow provide further descriptions of the regional planning activities and investment recommendations scheduled for each of the regions and sub-regions over the 2020 to 2024 period for which Hydro One is the lead transmitter. A letter from the IESO on the overall regional planning status is presented in Attachment 1.

Hydro One is also required by Section 3C.2.2 of the Transmission System Code to provide Planning Status Letters to licensed distributors and transmitters confirming the status of regional planning for a region, suitable for the purpose of supporting an application proposed to be filed with the Board by the distributor or requesting transmitter. In addition to the Planning Status Letters outlined in Appendix B of the 2018 Status Report, Hydro One has recently provided a Planning Status Letter to Kitchener-Wilmot Hydro Inc., Algoma Power Inc., and Alectra Utilities Corporation.

Note 1: The planning activity in the region was already in progress prior to the commencement of the regional planning process; hence the NA/SA was deemed to be already completed by the Study Team.

The Study Teams in the various regions, with input from relevant stakeholders, have recommended more than 60 projects related to transmission investments through the first cycle of regional planning process; with additional needs being identified in the second cycle. The scope and details of these projects are discussed in the corresponding regional planning reports. The specific information on the status of the regional planning process and investments arising from the recommendations of the Study Team that form part of Hydro One's capital plans over the 2020 to 2024 period are highlighted below by each Region Group.

Regions in Group 1

There are nine regions identified in Group 1. Hydro One Transmission is the lead transmitter for all regions in this group. The first cycle of regional planning process has been completed and the second cycle has commenced in six of the nine regions.

Burlington to Nanticoke

The Burlington to Nanticoke region is comprised of four sub-regions: **Brant, Bronte, Greater Hamilton,** and **Caledonia-Norfolk**. The participants in the region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Alectra Inc. (formerly Horizon Utilities Corp.)
- Brantford Power Inc.
- Burlington Hydro Electric Inc.
- Energy + Inc.
- Hydro One Networks Inc. (Distribution)
- Oakville Hydro Electricity Distribution Inc.

The first cycle RIP for this region was completed in February 2017 and is presented in Attachment 2 of this Exhibit. In addition to advancing the work from the IRRP presented in Hydro One's previous rate application (EB-2016-0160), the RIP also identified additional needs related to end-of-life transmission assets in the Hamilton area. The plans to address these end-of-life needs have been developed by Hydro One and confirmed by the region's LDC's.

As documented in Hydro One's previous rate application, the project to install 115kV switching facilities at Brant TS *(Project D09 in EB-2016-0160)* was identified as one of the transmission infrastructure investments required for the region. This investment along with the following system renewal investments, recommended in the RIP are continuing to be developed and are expected for in-service in 2019.

- **Beach TS:** Transformer (T3/T4) Replacement; and
- **Bronte TS:** Transformer (T5/T6) and DESN Refurbishment.

In response to the remaining RIP recommendations, this TSP contemplates the following investments over the 2020 to 2024 period:

- **Beach TS:** Auto-Transformer (T7/T8) Replacement and DESN Switchgear (Part of SR-03);
- **Birmingham TS:** MV Metalclad Switchgear Refurbishment (Part of SR-05);
- **Dundas TS:** MV Switchyard Refurbishment (Part of SR-06);
- **Dundas TS #2:** Two New Feeder Positions (SA Other Projects);
- **Elgin TS:** Transformer and DESN Reconfiguration (Part of SR-02);
- **Gage TS:** Transformer and DESN Reconfiguration (Part of SR-02);
- **Kenilworth TS:** Transformer and DESN Reconfiguration (Part of SR-02);
- **Lake TS:** LV Switchyard Refurbishment (Part of SR-06);
- **Newton TS:** Station Refurbishment (Part of SR-05);
- **115kV B3/B4 Transmission Line:** Refurbish line sections from Horning Mountain Junction to Glanford Junction (Part of SR-19); and

- **115kV B7/B8 Transmission Line:** Refurbish line sections from Burlington TS to Nelson Junction (SR Other Projects).

The second cycle NA report[4] for this region was completed in May 2017. The NA continues to reaffirm the needs identified in the first cycle RIP and has identified the need for the following additional system renewal investments over the 2020 to 2024 period:

- **Burlington TS:** LV Switchyard Refurbishment (Part of SR-06); and
- **Norfolk TS:** LV Switchyard Refurbishment (Part of SR-06).

The second cycle IRRP phase led by the IESO was completed in February 2019; and now the RIP phase led by Hydro One is currently underway.

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Greater Ottawa

The Greater Ottawa Region is comprised of two sub-regions: **Ottawa Area** and **Outer Ottawa**. The participants in the region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Hydro Hawkesbury Inc.
- Hydro One Networks Inc. (Distribution)
- Hydro Ottawa Limited
- Ottawa River Power Corporation

[4] https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/burlingtontonanticoke/Documents/Needs%20Assessment_Burlington%20to%20Nanticoke_May15_2017.pdf

The RIP for this region was completed in December 2015 and was provided in Hydro One's previous rate application (EB-2016-0160). For completeness, a copy is provided in Attachment 3 to this Exhibit.

As documented in Hydro One's previous rate application, the RIP identified the following three transmission infrastructure investments that were expected to be completed over the 2017 to 2019 period:

- **Circuit A4K Capacity:** Addition of 115kV tap *(Project D10 in EB-2016-0160);*
- **Lisgar TS:** Transformer Replacement *(Project D16 in EB-2016-0160)*; and
- **Overbrook TS:** Transformer (T1/T2) Replacement.

These investments are either complete or are continuing to be developed for in-service in 2019, with the exception of the Lisgar TS investment that has been deferred after further evaluation of the need. Load growth in the region will be monitored for further reassessment in the next regional planning cycle to determine the need for this project.

In response to the remaining RIP recommendations for this region, this TSP contemplates the following investments over the 2020 to 2024 period:

- **Hawthorne TS:** Transformer (T7/T8) Replacement (Part of SR-05);
- **Hawthorne TS:** Autotransformer (T5/T6) Replacement (SS Other Projects);
- **King Edward TS:** Transformer Replacement (Part of SR-05); and
- **Supply for New Station in Southwest Area** (Project SS-11).

The second cycle NA report[5] for this region was published in June 2018. The NA continues to reaffirm the needs identified in the first cycle RIP and has identified the need for the following additional system renewal investments over the 2020 to 2024 period:

---

[5]https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/greaterottawa/Documents/Greater%20Ottawa%20Needs%20Assessment%202018.pdf

- **Arnprior TS:** Transformer (T1/T2) Replacement (Part of SR-02);
- **Longueuil TS:** Transformer (T3/T4) Replacement (Part of SR-05);
- **Slater TS:** Transformer (T1/T2/T3) Replacement (Part of SR-02); and
- **115kV S7M Transmission Line:** Refurbish line sections (SR Other Projects).

The second cycle IRRP phase led by the IESO is currently underway; with the RIP for this region to be initiated and developed upon the completion of this IRRP.

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

GTA East

The GTA East Region is comprised of two sub-regions: **Pickering-Ajax-Whitby** and **Oshawa-Clarington**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Hydro One Networks Inc. (Distribution)
- Oshawa PUC Networks Inc.
- Veridian Connections Inc.
- Whitby Hydro Electric Corporation

The RIP for this region was completed in January 2017 and is provided in Attachment 4 to this Exhibit. This RIP advances the work from the IRRP documented in Hydro One's previous rate application (EB-2016-0160) with no additional needs or investment plans identified.

As documented in Hydro One's previous rate application, there were two transmission infrastructure investments identified for the region, including:

- Connection of a new station "**Enfield TS**" *(Project D21 in EB-2016-0160)*; and
- Connection of a new station "**Seaton MTS**" *(Project D17 in EB-2016-0160)*.

These investments are continuing to be developed and are expected in-service in the 2019 to 2020 period.

At this time, no further regional planning transmission infrastructure investments are expected over the 2020 to 2024 planning period.

GTA North

The GTA North Region is comprised of two sub-regions: **York** and **Western**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Alectra Inc. (formerly Enersource Hydro Mississauga Inc., Hydro One Brampton Networks Inc. and PowerStream Inc.)
- Hydro One Networks Inc. (Distribution)
- Newmarket-Tay Power Distribution Ltd.
- Toronto Hydro-Electric System Limited ("THESL")

The RIP for this region was completed in February 2016 and was presented in Hydro One's previous rate application (EB-2016-0160). For completeness, a copy is included in Attachment 5 to this Exhibit.

As documented in Hydro One's previous rate application, the RIP identified three transmission infrastructure investments over the 2017 to 2018 period. These investments have been completed and placed in-service, including the connection of a new load station "Vaughan #4 MTS"; the installation of breakers and switches at Holland TS; and the installation of two inline switches on the 230kV circuits V71P/V75P at Grainger Junction.

The second cycle NA report[6] for this region was completed in March 2018. The NA has identified the need for the following investments over the 2020 to 2024 period:

- Connection of a new load station "**Markham #5 MTS**" (SA Other Projects); and
- **Woodbridge TS:** Transformer (T5) Replacement (Part of SR-05).

The second cycle IRRP phase led by the IESO is currently underway; with the RIP for this region to be initiated and developed upon the completion of this IRRP.

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

GTA West

The GTA West Region is comprised of two sub-regions: **Northwestern** and **Southern**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO

[6] https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/gtanorth/Documents/Needs%20Assessment%20Report%20-%20GTA%20North%20Region.pdf

- Alectra Inc. (formerly Enersource Hydro Mississauga Inc. and Hydro One Brampton Networks Inc.)
- Burlington Hydro Electric Inc.
- Halton Hills Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

The RIP for this region was completed in January 2016 and was presented in Hydro One's previous rate application (EB-2016-0160). For completeness, a copy is included in Attachment 6 to this Exhibit.

In response to the RIP recommendations, this TSP contemplates the following investments over the 2020 to 2024 period:

- Connection of a new load station "**Halton TS #2**" (Project SA-03);
- **Milton SS:** Station Expansion and Connect 230kV circuits (Project SS-07); and
- **Reconductor 230kV H29/H30 Transmission Line** (SA Other Projects).

Further details on this investment are provided in TSP Section 3.3.8 Investment Summary Documents.

Kitchener-Waterloo-Cambridge-Guelph ("KWCG")

The KWCG Region includes the municipalities of Kitchener, Waterloo, Cambridge and Guelph, as well as portions of Perth and Wellington counties and associated townships in the area. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO

- Cambridge and North Dumfries Hydro Inc.
- Centre Wellington Hydro
- Guelph Hydro Electric System Inc.
- Halton Hills Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Kitchener-Wilmot Hydro Inc.
- Milton Hydro Distribution Inc.
- Waterloo North Hydro Inc.
- Wellington North Power Inc.

The RIP for this region was completed in December 2015 and was presented in Hydro One's previous rate application (EB-2016-0160). For completeness, a copy is included in Attachment 7 to this Exhibit.

As documented in Hydro One's previous rate application, the RIP identified several transmission infrastructure investments to be completed over the 2016 to 2017 period. These investments have been completed and placed in-service, including the investment for the installation of in-line switches on circuits M20D/M21D at Galt Junction.

The second cycle NA report[7] for this region was published in December 2018. The NA has identified the need for the following system renewal investments over the 2020 to 2024 period:

- **Cedar TS:** Transformer (T7/T8) Replacement (Part of SR-05);
- **Detweiler TS:** Autotransformer (T2/T4) Replacement (Part of SR-03);
- **Hanlon TS:** Transformer (T1/T2) Replacement (Part of SR-05); and
- **Preston TS**: Transformer (T3/T4) Replacement (Part of SR-05).

[7] https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/kitchenerwaterloocambridgeguelph/Documents/KWCG%20Needs%20Assessment%202018.pdf

The second cycle IRRP phase led by the IESO is currently underway; with the RIP for this region to be initiated and developed upon the completion of this IRRP.

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Metro Toronto

The Metro Toronto Region is comprised of two sub-regions: **Central Downtown** and **Northern**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Alectra Inc. (formerly Enersource Hydro Mississauga Inc. and PowerStream Inc.)
- Hydro One Networks Inc. (Distribution)
- THESL
- Veridian Connections Inc.

The RIP for this region was completed in January 2016 and was presented in Hydro One's previous rate application (EB-2016-0160). For completeness, a copy is provided in Attachment 8 to this Exhibit.

As documented in Hydro One's previous rate application, the RIP identified several near-term transmission infrastructure investments for the region, including:

- **Horner TS:** Addition of a second transformer station (Project SA-02);
- **Manby TS:** Autotransformer overload protection scheme;
- **Runnymede TS:** Expansion of transformer station and reconductor the 115kV circuits (*Project D19 in EB-2016-0160*); and
- **Southwest GTA Transmission Reinforcement** (Project SS-14).

The investments at Runnymede TS and Manby TS were completed and placed in-service in 2018. The other two investments, along with the connection for Copeland MTS Phase 2, are expected to be in-service over the 2020 to 2024 period.

The second cycle NA report[8] for this region was published in October 2017. The NA continues to reaffirm the needs identified in the first cycle RIP and has identified the need for the following additional system renewal investments over the 2020 to 2024 period:

- **Bermondsey TS:** Transformer (T3/T4) Replacement (Part of SR-05);
- **Bridgman TS:** Transformer (T11-T13) Replacement (Part of SR-05);
- **Charles TS:** Transformer (T3/T4) Replacement (Part of SR-05);
- **Duplex TS:** Transformer (T1/T2) Replacement (Part of SR-05);
- **Fairbank TS:** Transformer (T1-T4) Replacement (Part of SR-02);
- **Fairchild TS:** Transformer (T1/T2) Replacement (Part of SR-05);
- **John TS:** Station Reinvestment (Part of SR-08);
- **Leslie TS:** Transformer (T1) Replacement (Part of SR-05);
- **Main TS:** Transformer (T3/T4) Replacement (Part of SR-05);
- **Manby TS:** Transformer (T7/T9/T12/T13) and 230kV Component Replacement (Part of SR-03);
- **Runnymede TS:** Transformer (T3/T4) Replacement (Part of SR-02);
- **Sheppard TS:** Transformer (T3/T4) Replacement (Part of SR-02);
- **Strachan TS:** Transformer (T12) Replacement (Part of SR-05);
- **115kV C5E/C7E Underground Cables:** Refurbish cable sections from Esplanade TS to Terauley TS (Part of SR-27);
- **115kV H1L/H3L/H6LC/H8LC Transmission Lines**: Refurbish line sections from Leaside Junction to Bloor St. Junction (Part of SR-19); and

[8] https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/metrotoronto/Documents/Needs%20Assessment%20-%20Toronto%20Region%20-%20Final.pdf

- **115kV L9C/L12C Transmission Lines:** Refurbish line sections from Leaside TS to Balfour Junction (SR Other Projects).

The second cycle IRRP phase led by the IESO is currently underway; with the RIP for this region to be initiated and developed upon the completion of this IRRP.

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Northwest Ontario

The Northwest Ontario Region is comprised of several sub-regions: **North of Dryden, Greenstone-Marathon, City of Thunder Bay,** and **West of Thunder Bay**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Atikokan Hydro Inc.
- Fort Frances Power Corporation
- Hydro One Networks Inc. (Distribution)
- Kenora Hydro Electric Corporation Ltd.
- Sioux Lookout Hydro Inc.
- Thunder Bay Hydro Electricity Distribution Inc.

The RIP for this region was completed in June 2017 and is presented in Attachment 9 to this Exhibit. This RIP advances the work from the IRRP documented in Hydro One's previous rate application (EB-2016-0160).

In response to the RIP recommendations, this TSP contemplates the following investment over the 2020 to 2024 period:

- Connection to the new 230kV transmission line from Dryden/Ignace area to Pickle Lake (Project SS-02).

Further details on this investment are provided in TSP Section 3.3.8 Investment Summary Documents.

Windsor-Essex

The Windsor-Essex Region is in the southern-most part of Ontario, extending from Chatham southwest to Windsor. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- E.L.K. Energy Inc.
- Entegrus Powerlines Inc.
- EnWin Utilities Ltd.
- Essex Powerlines Corporation
- Hydro One Networks Inc. (Distribution)

The RIP for this region was completed in December 2015 and was presented in Hydro One's previous rate application (EB-2016-0160). For completeness, a copy is provided in Attachment 10 to this Exhibit.

As documented in Hydro One's previous rate application, the RIP identified several near-term transmission infrastructure investments for this region, including:

- **Keith TS:** Autotransformer Replacement (Part of SR-03);
- **Keith TS:** Reconfiguration due to the Gordie Howe International Bridge;

- **Kingsville TS:** Transformer Replacement (Part of SR-05); and
- **Supply to Essex County Transmission Reinforcement.**

These investments are either complete and/or continue to be developed for in-service in 2019; with the exception for the second Kingsville TS transformer and the Keith transformer replacements that are planned for in-service over the 2020 to 2024 period.

The second cycle NA report[9] for this region was completed in October 2017. The NA continues to reaffirm the needs identified in the first cycle RIP and has identified the need for the following investments over the 2020 to 2024 period:

- **Malden TS:** Additional feeder positions (SA Other Projects); and
- **Lauzon TS:** Transformer (T6/T8) and Component Replacement (Part of SR-05).

In addition to these investments, the need for transmission reinforcement in the Leamington Area has been highlighted in assessment work undertaken by the IESO in the development of their 2019 Windsor-Essex Integrated Regional Resource Plan. To ensure customer needs are addressed in a timely manner, this TSP contemplates the Leamington Area transmission reinforcement and the building of a second 230/27.6kV DESN (Project SS-13) to address the need.

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Regions in Group 2

There are five regions in Group 2 for which the first cycle of the regional planning process has been completed. Hydro One Transmission is the lead transmitter for all regions in this group with the exception of the East Lake Superior region.

[9]https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/windsoressex/Documents/Needs%20Assessment_Windsor-Essex_Final.pdf

London Area

The London Area Region is comprised of five sub-regions: **Greater London, Aylmer-Tillsonburg, Strathroy, Woodstock,** and **St. Thomas**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Entegrus Powerlines Inc.
- Erie Thames Powerlines Corporation
- Hydro One Networks Inc. (Distribution)
- London Hydro Inc.
- St. Thomas Energy Inc.
- Tillsonburg Hydro Inc.

The RIP for this region was completed in August 2017 and is provided in Attachment 11 of this Exhibit. This RIP advances the work from the IRRP documented in Hydro One's previous rate application (EB-2016-0160).

In response to the RIP recommendations, this TSP contemplates the following investments over the 2020 to 2024 period:

- **Aylmer-Tillsonburg Area Transmission Reinforcement** (Project SS-12); and
- **Wonderland TS:** Station Refurbishment (Part of SR-02).

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Peterborough to Kingston

The Peterborough to Kingston Region includes the area roughly bordered geographically by the municipality of Clarington on the West, North Frontenac County on the North, Frontenac County on the East, and Lake Ontario on the South. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Hydro One Networks Inc. (Distribution)
- Kingston Hydro
- Peterborough Distribution Inc.
- Veridian Connections Inc.

The RIP for this region was completed in July 2016 and is provided in Attachment 12 of this Exhibit. The RIP identified that the needs for this region were strictly local in nature. Local plans have been developed by Hydro One and the impacted LDCs in the area to balance the Gardiner TS load. In addition, the IESO will assess and develop a plan for contingencies associated with the 115kV circuit (Q6S) and 230kV circuit (P15C) as part of the IESO-led bulk system planning study. At this time, no further regional planning transmission infrastructure investments are contemplated over the 2020 to 2024 planning period.

South Georgian Bay/Muskoka

The South Georgian Bay/Muskoka Region is comprised of two sub-regions: **Barrie/Innisfil** and **Parry Sound/Muskoka**. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO

- Alectra Inc. (formerly PowerStream Inc.)
- Hydro One Networks Inc. (Distribution)
- InnPower Corporation
- Orangeville Hydro Ltd.
- Veridian Connections Inc.

The RIP for this region was completed in August 2017 and is provided in Attachment 13 of the Exhibit. This RIP advances the work from the IRRP documented in Hydro One's previous rate application (EB-2016-0160) and interim letter from the IESO to commence work to address equipment approaching end-of-life at Barrie TS.

In response to the RIP recommendations, this TSP contemplates the following investments over the 2020 to 2024 period:

- **Barrie Area Transmission Upgrade** (Project SS-09);
- **Minden TS:** Transformer Replacement, LV Switchyard Rebuild (Part of SR-05);
- **Orangeville TS:** Transformer (T1/T2) Replacement (Part of SR-05); and
- **Parry Sound TS:** Transformer Replacement (Part of SR-05).

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Sudbury/Algoma

The Sudbury/Algoma Region includes the Greater Sudbury Area, Manitoulin Island, and Townships of Verner, Warren, Elliot Lake, Blind River, and Walden. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Greater Sudbury Hydro

- Hydro One Networks Inc. (Distribution)

The RIP for this region was completed in June 2016 and is provided in Attachment 14 of this Exhibit. Local plans have been implemented by Hydro One to address the Manitoulin TS Low Voltage Regulation. Furthermore, the recommendation for a new 230/44kV Station at Hanmer TS identified in the RIP and documented in Hydro One's previous rate application for in-service in 2019 has been deferred after further evaluation of the need and customer consultation. Load growth in the region will be monitored for further reassessment in the next regional planning cycle to determine the need for this project.

At this time, no further regional planning transmission infrastructure investments are contemplated over the 2020 to 2024 planning period.

East Lake Superior

The East Lake Superior region spans the area from Wawa to north of Thessalon. Formerly, Great Lakes Power Transmission LP ("GLPT") was the lead transmitter for this region. GLPT conducted the regional process in late 2014 including representatives from the IESO, Hydro One Networks, Algoma Power Inc., PUC Distribution and Chapleau Public Utility Corporation. Through this process, it was determined that there were no electricity needs in the next ten years requiring regional coordination.

In October 2016, Hydro One Inc. acquired GLPT and is operating the transmission business through a separate subsidiary known as Hydro One Sault Saint Marie ("Hydro One SSM"). As such, the lead transmitter for this region is now Hydro One SSM. This TSP does not contemplate any regional planning transmission infrastructure investments in this region during the 2020 to 2024 planning period.

Regions in Group 3

There are seven regions in Group 3 for which the first cycle of the regional planning process has been completed. Hydro One Transmission is the lead transmitter for all regions in this group with the exception of the North of Moosonee region.

Chatham/Lambton/Sarnia

The Chatham-Lambton-Sarnia Region includes the municipalities of Lambton Shores and Chatham-Kent, as well as associated townships in the area. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Bluewater Power Distribution Corporation
- Entegrus Powerlines Inc.
- Hydro One Networks Inc. (Distribution)

The RIP for this region was completed in August 2017 and is provided in Attachment 15 of this Exhibit. The RIP identified that the needs for this region were strictly local in nature and no transmission infrastructure investment is required. Local plans have been implemented by Hydro One to address a capacity issue at Kent TS. In addition to the local needs, the RIP also identified several system renewal investments for the region. In response to the recommendations made in the RIP report, this TSP contemplates the following investments over the 2020 to 2024 period:

- **St. Andrews TS:** Transformer (T3/T4) Replacement and DESN Refurbishment (Part of SR-02); and
- **Sarnia Scott TS:** Transformer (T5) and component Replacement (Part of SR-03).

Further details on these investments are provided in TSP Section 3.3.8 Investment Summary Documents.

Greater Bruce / Huron

The Greater Bruce/Huron region includes the municipalities of Arran–Elderslie, Brockton, Kincardine, Northern Bruce Peninsula, and South Bruce. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Entegrus Powerlines Inc.
- Erie Thames Powerlines Corporation
- Festival Hydro Inc.
- Goderich Hydro - West Coast Huron Energy Inc.
- Hydro One Networks Inc. (Distribution)
- Wellington North Power Inc.
- Westario Power Inc.

The RIP for this region was completed in August 2017 and is provided in Attachment 16 to this Exhibit. The RIP identified a local need to improve L7S customer delivery point performance. Further assessment work outside the regional planning process is in progress for this local need to identify alternatives and develop mitigation plans. At this time, no further regional planning transmission infrastructure investments are expected over the 2020 to 2024 planning period.

Niagara

The Niagara Region comprises twelve municipalities in the southern end of the Golden Horseshoe. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO

- Alectra Inc. (formerly Horizon Utilities Corp.)
- Canadian Niagara Power Inc.
- Grimsby Power Inc.
- Haldimand County Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Niagara Peninsula Energy Inc.
- Niagara-on-the-Lake Hydro Inc.
- Welland Hydro Electric System Corp.

The RIP for this region was completed in March 2017 and is provided in Attachment 17 to this Exhibit. The RIP identified that the needs for this region were strictly local in nature. Local plans have been implemented by Hydro One to address thermal overloading of the 115kV circuit (Q4N) by upgrading the conductor on a section of Q4N from Beck 1 SS to Portal Junction. At this time, no further regional planning transmission infrastructure investments are contemplated over the 2020 to 2024 planning period.

North/East of Sudbury

The North/East of Sudbury Region is the area roughly bordered by Moosonee to the North, Hearst to the North-West, Ferris to the South, and Kirkland Lake to the East. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Hearst Power Ltd.
- Hydro One Networks Inc. (Distribution)
- North Bay Hydro Distribution Ltd.
- Northern Ontario Wires Inc.

The RIP for this region was completed in April 2017 and is provided in Attachment 18 to this Exhibit. The RIP identified that the needs for this region were strictly local in nature. Local plans were developed by Hydro One and the impacted LDCs in the area to address Timmins TS/Kirkland Lake TS voltage regulation issues. At this time, no further regional planning transmission infrastructure investments are contemplated over the 2020 to 2024 planning period.

Renfrew

The Renfrew Region includes all of Renfrew County. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Hydro One Networks Inc. (Distribution)
- Ottawa River Power Corporation
- Renfrew Hydro Inc.

The RIP for the region was completed in July 2016 and is provided in Attachment 19 to this Exhibit. The RIP identified that there were no capacity, system reliability or operating needs that required investments over the planning horizon. As such, this TSP does not contemplate any transmission infrastructure investments for this region over the 2020 to 2024 period resulting from the regional planning process.

St. Lawrence

The St. Lawrence Region covers the southeastern part of Ontario bordering the St. Lawrence River. The participants in this region's Study Team include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)

- IESO
- Hydro One Networks Inc. (Distribution)

The RIP for this region was completed in July 2016 and is provided in Attachment 20 to this Exhibit. The RIP identified that there were no capacity, system reliability or operating needs that required investments over the planning horizon. As such, this TSP does not contemplate any transmission infrastructure investment for this region over the 2020 to 2024 period resulting from the regional planning process.

North of Moosonee

Five Nations Energy Inc. ("FNEI") is the lead transmitter for this region and is therefore responsible for the RIP. This TSP does not contemplate any regional planning transmission infrastructure investments in this region.

VIA EMAIL

Mr. Ajay Garg
Manager, Regional Transmission Planning
Hydro One Networks Inc.
483 Bay Street
Toronto, ON
M5G 2P5

Dear Mr. Garg:

Re: Independent Electricity System Operator
Regional Planning Progress Update

The Independent Electricity System Operator ("IESO") has been notified by Hydro One Networks Inc. ("Hydro One") of its upcoming 2020-2022 rate application to the Ontario Energy Board ("OEB") and has been requested to provide Hydro One with a regional planning status update for the planning regions in the province. This request includes regional planning areas undergoing either a Needs Assessment ("NA"), Scoping Assessment ("SA") or an Integrated Regional Resource Planning ("IRRP").

Hydro One's request is based on the requirement of section 2.4.2 of the OEB's Chapter 2 Filing Requirements for Electricity Transmission Applications which states:

> *Where regional planning is underway, but a Regional Infrastructure Plan has not yet been completed for the applicable region, the applicant shall submit a letter from the Independent Electricity System Operator ("IESO"), identifying the status of the regional planning process, and the potential impacts on the applicant's investment plans.*

Pursuant to the above referenced filing requirements, the IESO hereby provides the status of regional planning as follows.

The first cycle of regional planning for all 21 regions was completed in Q3, 2017 and the second cycle has started for some of the regions in Group 1. The table below provides the status of the regional plans that are presently underway; regional planning for regions that are not listed in this table have not yet started.

Table 1: Active regions in second round of Regional Planning

Group 1 Regions	Sub-Regions	Status	Expected Completion Date of the Stage that is in Progress
Burlington to Nanticoke	Brant	NA/SA completed. IRRP in progress for the Greater Hamilton sub-region.	Q1 2019
	Bronte		
	Greater Hamilton		
	Caledonia-Norfolk		
Greater Ottawa	Ottawa	NA/SA completed. IRRP in progress for the Outer Ottawa sub-region.	Q3/Q4 2019
	Outer Ottawa		
GTA North	York	NA/SA completed. IRRP in progress for the York sub-region.	Q4 2019
	Western		
GTA West	Northwestern	NA underway.	Q1 2019
	Southern		
KWCG	No sub-regions	NA completed. SA in progress.	Q1 2019
Toronto	No sub-regions	NA/SA completed. IRRP in progress.	Q4 2019
Northwest Ontario	North of Dryden	NA in progress.	Q1 2019
	Greenstone-Marathon		
	Thunder Bay		
	West of Thunder Bay		
Windsor-Essex	No sub-regions	NA/SA completed. IRRP in progress.	Q3 2019

During the second cycle of regional planning, the Regional Planning Study Team is giving greater consideration to assets reaching end of life. More specifically, they are considering opportunities to "right size" equipment, the potential reliability impact of the longer-term outages required to carry out significant replacement projects, and the potential to optimize the system design as part of the scope of the asset replacement. Therefore, while investments would most likely be necessary to address assets reaching end of life, in some cases the specific investment required may depend on the outcome of the regional planning processes that are presently underway.

If you have any questions about the IESO's comments please contact me directly at 905-855-6340 or Devon.Huber@ieso.ca.

Yours truly,

Devon Huber
Senior Manager, Regulatory Affairs

Burlington to Nanticoke

REGIONAL INFRASTRUCTURE PLAN

February 7, 2017

hydro one

[This page is intentionally left blank]

Prepared and supported by:

Company
Brantford Power Inc.
Burlington Hydro Inc.
Energy + Inc.
Alectra Utilities Corporation (former Horizon Utilities Inc.)
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator (IESO)
Oakville Hydro
Hydro One Networks Inc. (Lead Transmitter)

[This page is intentionally left blank]

Disclaimer

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH PARTICIPATION AND INPUT FROM THE RIP WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE PLANNED, DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE BURLINGTON TO NANTICOKE REGION.

The participants of the RIP Working Group included members from the following organizations:

- Brantford Power Inc.
- Burlington Hydro Inc.
- Energy + Inc.
- Alectra Utilities Corporation (former Horizon Utilities Inc.)
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator (IESO)
- Oakville Hydro
- Hydro One Networks Inc. (Lead Transmitter)

In general, the RIP is the final phase of the regional planning process and, in this case, it follows the completion of the Integrated Regional Resource Plans ("IRRP") for Brant Sub-Region and Bronte Sub-Region in March 2015 and June 2016, respectively, and the Burlington to Nanticoke Region's Needs Assessment ("NA") in May 2014. This RIP provides a consolidated summary of the needs and recommended plans for the Burlington to Nanticoke Region for the near-term (up to 5 years) and the mid-term (5 to 10 years).

It should be noted that this RIP, in addition to advancing the work from the aforementioned IRRPs, also identifies additional needs related to sustainment and end-of-life facilities in the Hamilton area. Built over 50 years ago, the transmission assets in the Hamilton area are some of the oldest installations in the province. At the time of the Burlington to Nanticoke Need Assessment and Scoping Assessment phases, done in 2014, the detailed information on the condition and end-of-life issues related to these assets was not available. As such, a decision was made by the Working Group at that time to not initiate a coordinated planning exercise for the Hamilton subsystem. Since then, through the RIP process, the extent and urgency of the sustainment work in the Hamilton area, and also in Oakville and Brantford, are better known to the Working Group.

This RIP discusses those needs and the projects developed to address those needs. Implementation to address some of these needs is underway. The plans presented in this RIP to address new end-of-life needs have been developed by Hydro One and needs also confirmed by the LDC. Further details are being formalized by Hydro One through assessment and consultation with the LDC to develop implementation plans. The plans for Beach TS, Birmingham TS, Gage TS and Kenilworth TS were later also reviewed by the IESO as part of an ongoing study for the Hamilton area. However, new near and mid-term needs namely Horning TS, Elgin TS, and Bronte TS were not fully identified earlier in the regional planning process and did not undergo a review by the IESO in the earlier phases due to their scope or project status.

The RIP report also identifies long-term needs associated with the revised and better defined sustainment plan.

The needs and/or plans in the near-term (2016-2020) and the mid- to long-term (beyond 2020) are provided below in Table 1 and Table 2, respectively, along with their planned in-service date and estimated cost, where applicable. Table 1 identifies both the stakeholders involved in each project's development and which formal regional planning process it originated from. The table also indicates the needs identified after the completion of the NA and SA (Scoping Assessment) processes.

Table 1: Near-Term Needs/Plans in Burlington to Nanticoke Region

No.	Needs	Plans	Status	I/S Date	Cost ($M)
Projects Developed in Local Planning or an IRRP					
1	115 kV B7/B8 Transmission Line Capacity	Bronte TS: Load Transfer	Planning	2018	1-3
2	115 kV B12/B13 Transmission Line Capacity	Install Brant Switching Station	Planning	2019	12
3	Two New Feeders at Dundas TS #2	Dundas TS: Load Transfer	Planning	2019	8
4	Cumberland TS – Power Factor Correction	LDC is developing distribution option	Planning	TBD (1)	-
5	Kenilworth TS – Power Factor Correction	LDC is developing distribution option	Planning	TBD (1)	-
Projects Developed by HONI & the LDC(s), Reviewed by IESO					
6	Kenilworth TS EOL transformers & switchgear (2)	Reconfigure from 2 DESNs to single DESN	Planning	2018	19
7	Beach TS – EOL T3/T4 DESN Transformers (2)	Replace Beach TS T3/T4 Transformers	Committed	2019	17
8	Gage TS – EOL transformers & switchgear	Gage TS: Reduce from 3 DESNs to 2 DESNs	Planning	2019	37
9	115 kV B7/B8 – EOL Line Section from Burlington TS to Nelson Jct. (2)	Refurbish the EOL B7/B8 line section	Planning	2020	2
Projects Developed by HONI & the LDC(s)					
10	115 kV B3/B4 – EOL Line Section from Horning Mountain Jct. to Glanford Jct. (2)	Refurbish the EOL B3/B4 line section conductor	Planning	2018	8
11	Horning TS EOL transformers & switchgears (2)	Replace EOL transformers & refurbish switchgears	Committed	2018	37
12	Bronte TS – EOL T5/T6 DESN (2)	Replace EOL transformers & refurbish switchgear	Committed	2019	34

No.	Needs	Plans	Status	I/S Date	Cost ($M)
13	Elgin TS – EOL transformers & switchgears	Replace transformers and switchgears and reduce 2 DESNs to 1 DESN	Committed	2019	58
14	Mohawk TS (T1/T2) – Station Capacity and EOL T1/T2 Transformers	Mohawk TS Transformers Replacement	Committed	2019	14

(1) To Be Decided
(2) New needs identified by HONI

Table 2: Mid- and Long-Term Needs/Plans in Burlington to Nanticoke Region

No.	Needs/Plans	Planned I/S Date	Cost ($M)
1	Birmingham TS: 2 Metal Clad Switchgear Refurbishment (1)	2021	14
2	Dundas TS: T1/T2 switchyard refurbishment	2021	10
3	Newton TS: Station Refurbishment	2021	36
4	LV Switchgear Refurbishment at Brantford TS, Lake TS and Stirton TS	2022	46
5	Beach TS: Replace EOL T7/T8 Autotransformers and refurbish T5/T6 DESN switchgear	2025	60
6	EOL 115 kV Cables: - H5K/ H6K - K1G/ K2G - HL3/ HL4	TBD (2)	TBD (2)

(1) Preliminarily reviewed by HONI, LDC and the IESO
(2) To Be Decided

Further details of needs, alternatives, and recommended plans for the above needs are provided in Section 7. The preliminary plans and needs identified in Table 2 will be further assessed in the next planning cycle. A summary of the current recommendations for these mid- and long-term needs is provided in Section 8.

The RIP Working Group recommends the following outcomes and next steps:

a) Hydro One will continue to implement the committed and near-term projects for addressing the above needs as discussed in this report, while keeping the Working Group apprised of project status, and

b) The RIP recommends that an expedited Needs Assessment report should be developed to list these already identified needs in the mid and long term or any new needs to be followed by Scoping Assessment, led by the IESO for further assessment under the Burlington to Nanticoke regional planning Working Group.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE BURLINGTON TO NANTICOKE REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the needs, assessments and recommended plan. The members of the RIP WG included representative from Brantford Power Inc. ("Brantford Power"), Burlington Hydro Inc. ("Burlington Hydro"), Energy + Inc. ("Energy +"), Alectra Utilities Corporation (former Horizon Utilities Inc. "Alectra Utilities"), Hydro One Distribution, the Independent Electricity System Operator ("IESO") and Oakville Hydro Electricity Distribution Inc. ("Oakville Hydro") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The Burlington to Nanticoke region covers the City of Brantford, municipality of Hamilton, counties of Brant, Haldimand and Norfolk. The portions of Cities of Burlington and Oakville south of Dundas Street are included in the Burlington to Nanticoke region up to Third Line road in the east. Electrical supply to the Region is provided from thirty-one 230 kV and 115 kV step-down transformer stations. The summer 2015 load of the Region was about 1831 MW. The boundaries of the Region are shown in Figure 1-1 below.

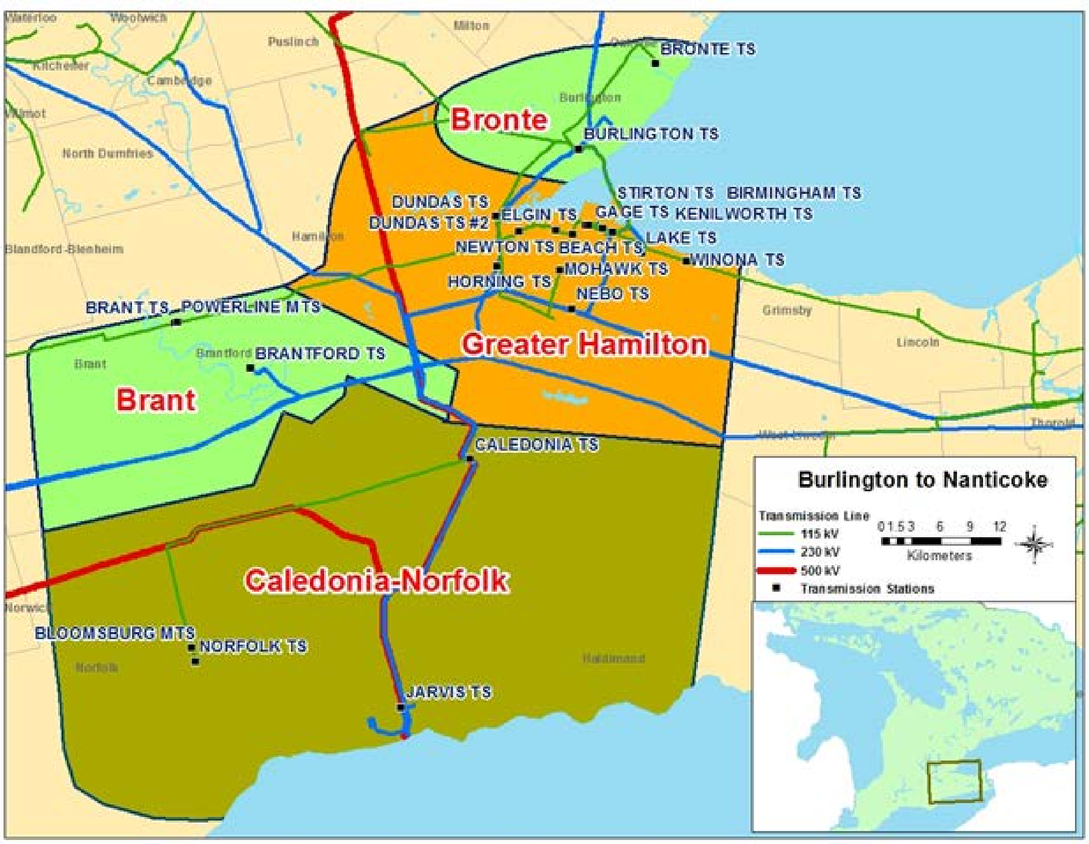

Figure 1-1 Burlington to Nanticoke Region

1.1 Objective and Scope

The RIP report examines the needs in the Burlington to Nanticoke Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs;
- Identify any new needs that may have emerged since previous planning phases e.g., Needs Assessment ("NA") and/or Integrated Regional Resource Plan("IRRP");
- Assess and develop a wires plan to address these new needs; and
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, major high voltage sustainment issues emerging over the mid- and long-term, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated summary of the wires plan developed during LP (Local Planning), SA (Scoping Assessment), and/or as identified in IRRP.
- Discussion of any other major transmission infrastructure investment plans over the near and mid-term (0-10 years)
- Identification of any new needs and a wires plan to address these needs based on new and/or updated information.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies needs.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

[1] Also referred to as Needs Screening

a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region. The Brant Sub-Region IESO led IRRP was initiated prior to the new regional planning process and was completed in March 2015. The need for Bronte Sub-Region IRRP was identified during the Need Assessment for Burlington to Nanticoke region and was completed in June 2016.

The RIP phase is the fourth and final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA, SA, and LP phases of regional planning.
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

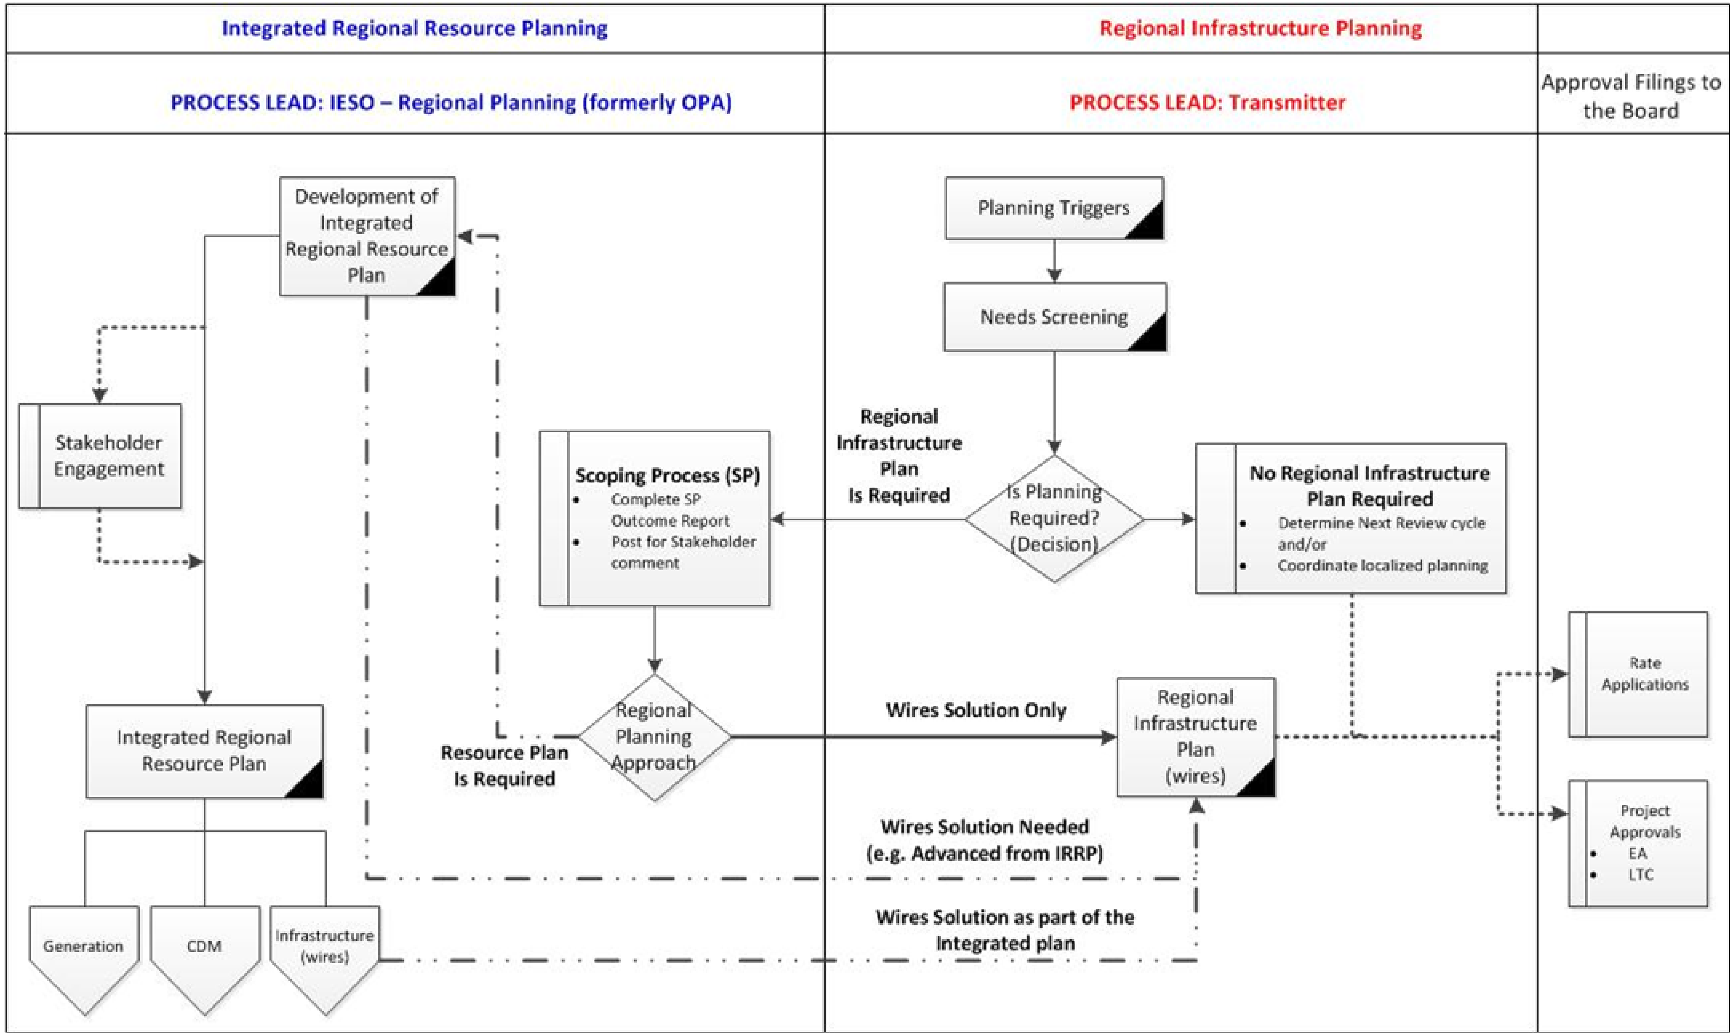

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous phase of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Depending upon the changes to load forecast or other relevant information, regional technical assessment may or may not be required or be limited to specific issue only. Additional near and mid-term needs may be identified in this phase.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

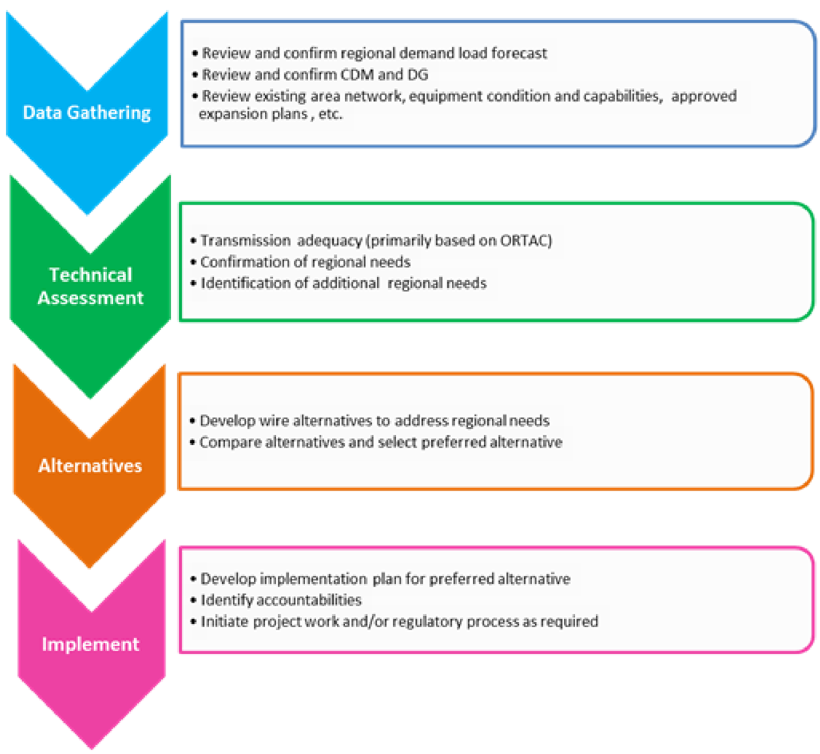

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE BURLINGTON TO NANTICOKE REGION COVERS THE CITY OF BRANTFORD, MUNICIPALITY OF HAMILTON, COUNTIES OF BRANT, HALDIMAND AND NORFOLK. SOME OF THE ELECTRICAL INFRASTRUCTURE IN THE REGION IS ONE OF THE OLDEST INSTALLATIONS IN THE PROVINCE. THE PORTIONS OF CITIES OF BURLINGTON AND OAKVILLE SOUTH OF DUNDAS STREET ARE INCLUDED IN THE BURLINGTON TO NANTICOKE REGION UP TO THIRD LINE ROAD IN THE EAST.

Bulk electrical supply to the Burlington to Nanticoke Region is provided through the 500/230 kV Nanticoke TS and Middleport TS and 230 kV circuits from Middleport TS, Nanticoke TS and Beck TS. The 115 kV network is supplied by 230/115 kV autotransformers at Burlington TS, Beach TS and Caledonia TS. The area loads are supplied by a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. The area has been divided into four sub-regions as shown in Figure 1-1 and described below:

- The Brant Sub-Region encompasses the County of Brant, City of Brantford and surrounding areas. Electricity supply to the sub-region is provided by:
  - Brant TS and Powerline MTS supplied by 115 kV double circuit line B12/B13.
  - Brantford TS supplied by the 230 kV double circuit transmission line M32W/M33W.

  The Brant Sub-Region transmission facilities are shown in Figure 3-1.

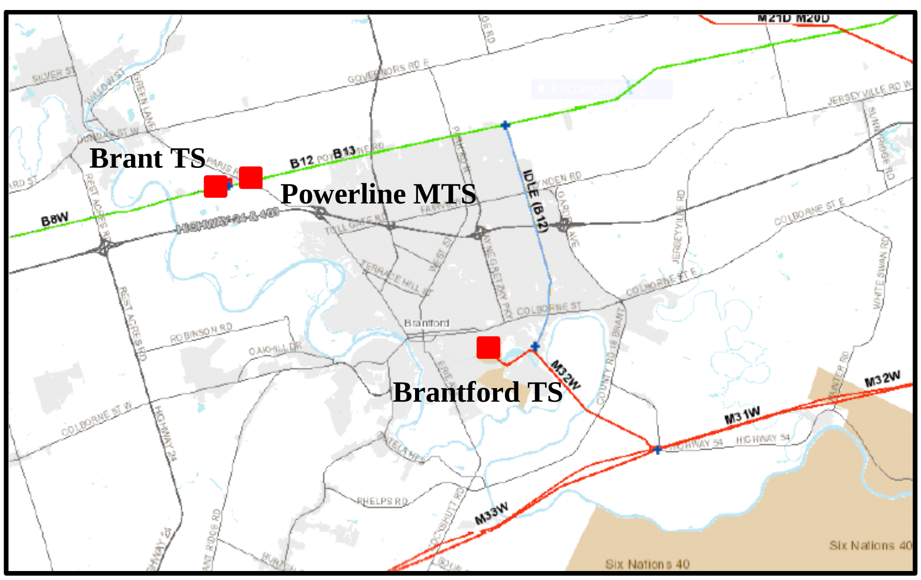

Figure 3-1 Brant Sub-Region

The total peak demand of the three stations was about 263 MW in 2015. Energy + Inc. and Brantford Power Inc. are the main LDCs that serve the electricity demand for the City of Brantford. Hydro One Distribution supplies load in the outlying areas of the sub-region. The electricity demand is comprised of residential, commercial and industrial customers.

- The Bronte Sub-Region covers the City of Burlington and the western part of the City of Oakville up to Third Line. Electricity supply to the sub-region is provided by:

  - Bronte TS supplied by 115 kV double circuit line B7/B8.
  - Burlington TS supplied by 230 kV double circuit line Q23BM/ Q25BM.
  - Cumberland TS supplied from 230 kV double circuit transmission line B40C/B41C.

  The Bronte Sub-Region transmission facilities are shown in Figure 3-2.

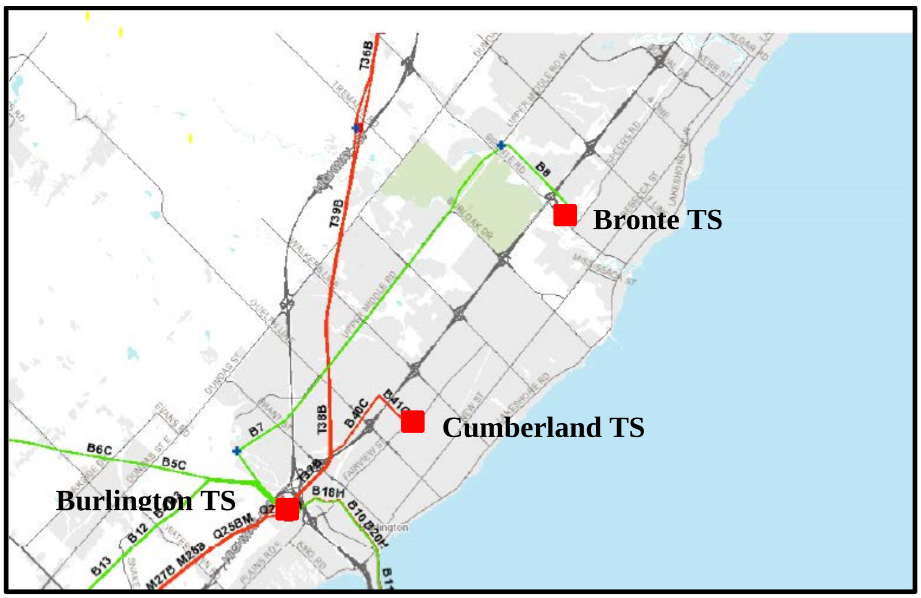

Figure 3-2 Bronte Sub-Region

The area is served by Burlington Hydro and Oakville Hydro. The electricity demand is comprised of residential, commercial and industrial customers. The total peak station demand of the three stations was about 402 MW in 2015.

- The Greater Hamilton Sub-Region encompasses the City of Hamilton that includes Townships of Flamborough and Glanbrook and towns of Dundas and Stoney Creek. Some of the electrical infrastructure in the sub-region was built over 50 years ago and is one of the oldest installations in the province. Electricity supply to the sub-region is grouped as follows:

  - Beach TS 115 kV area which includes five 115 kV step down stations Beach TS T3/T4 DESN, Birmingham TS, Kenilworth TS, Stirton TS, Winona TS and a CTS supplied from the 230/115 kV autotransformers at Beach TS.

- Burlington TS 115 kV area which includes Dundas TS, Dundas #2, Elgin TS, Gage TS, Mohawk TS, Newton TS and one customer owned CTS supplied from the 230/115 kV autotransformers at Burlington TS.

- 230 kV area which includes Beach TS T5/T6 DESN, Horning TS, Nebo TS, Lake TS and two customer owned stations supplied from 230 kV circuits connecting into Beach TS and Burlington TS.

The Greater Hamilton Sub-Region transmission facilities are shown in Figure 3-3.

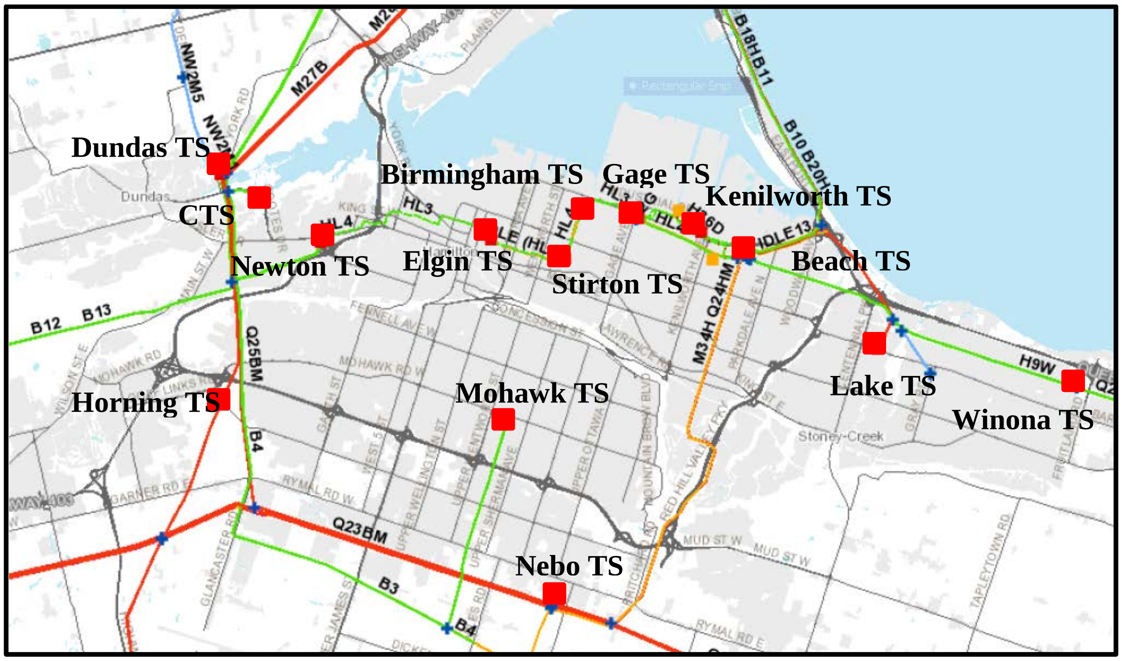

Figure 3-3 Greater Hamilton Sub-Region

The total peak station demand of the Greater Hamilton Sub-Region was about 1394 MW in 2015. The area is served by Alectra Utilities, Hydro One Distribution and CTSs comprises a significant number of large industrial customers along with commercial and residential customers.

- The Caledonia Norfolk Sub-Region covers the eastern part of Norfolk County and the western part of Haldimand County. Electricity supply to the Sub-region is provided by:

  - Caledonia TS supplied by 230 kV double circuit line N5M/S39M.
  - Jarvis TS supplied from the 230 kV double circuit line N21J/N22J.
  - Bloomsburg DS and Norfolk TS supplied from 115 kV double circuit transmission line C9/C12.

The Caledonia Norfolk Sub-Region transmission facilities are shown in Figure 3-4.

The area is served by Hydro One Distribution. The electricity demand mix is comprised of residential, commercial and industrial uses. The peak demand of the stations in the Sub-Region was approximately 334 MW in 2015.

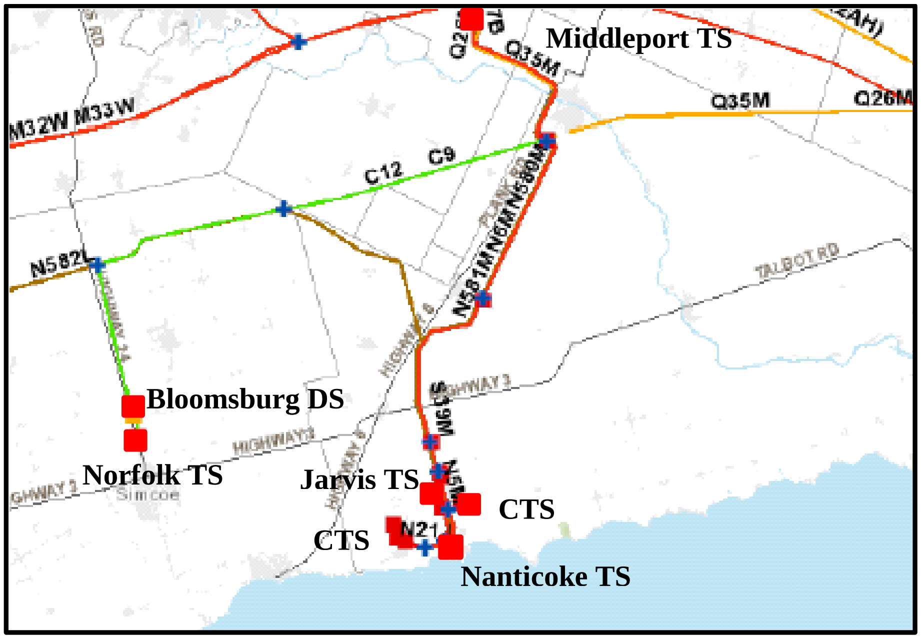

Figure 3-4 Caledonia Norfolk Sub-Region

Electrical single line diagrams for the Burlington to Nanticoke Region 500 kV/ 220 kV facilities and 115 kV facilities are shown below in Figure 3-5 and Figure 3-6.

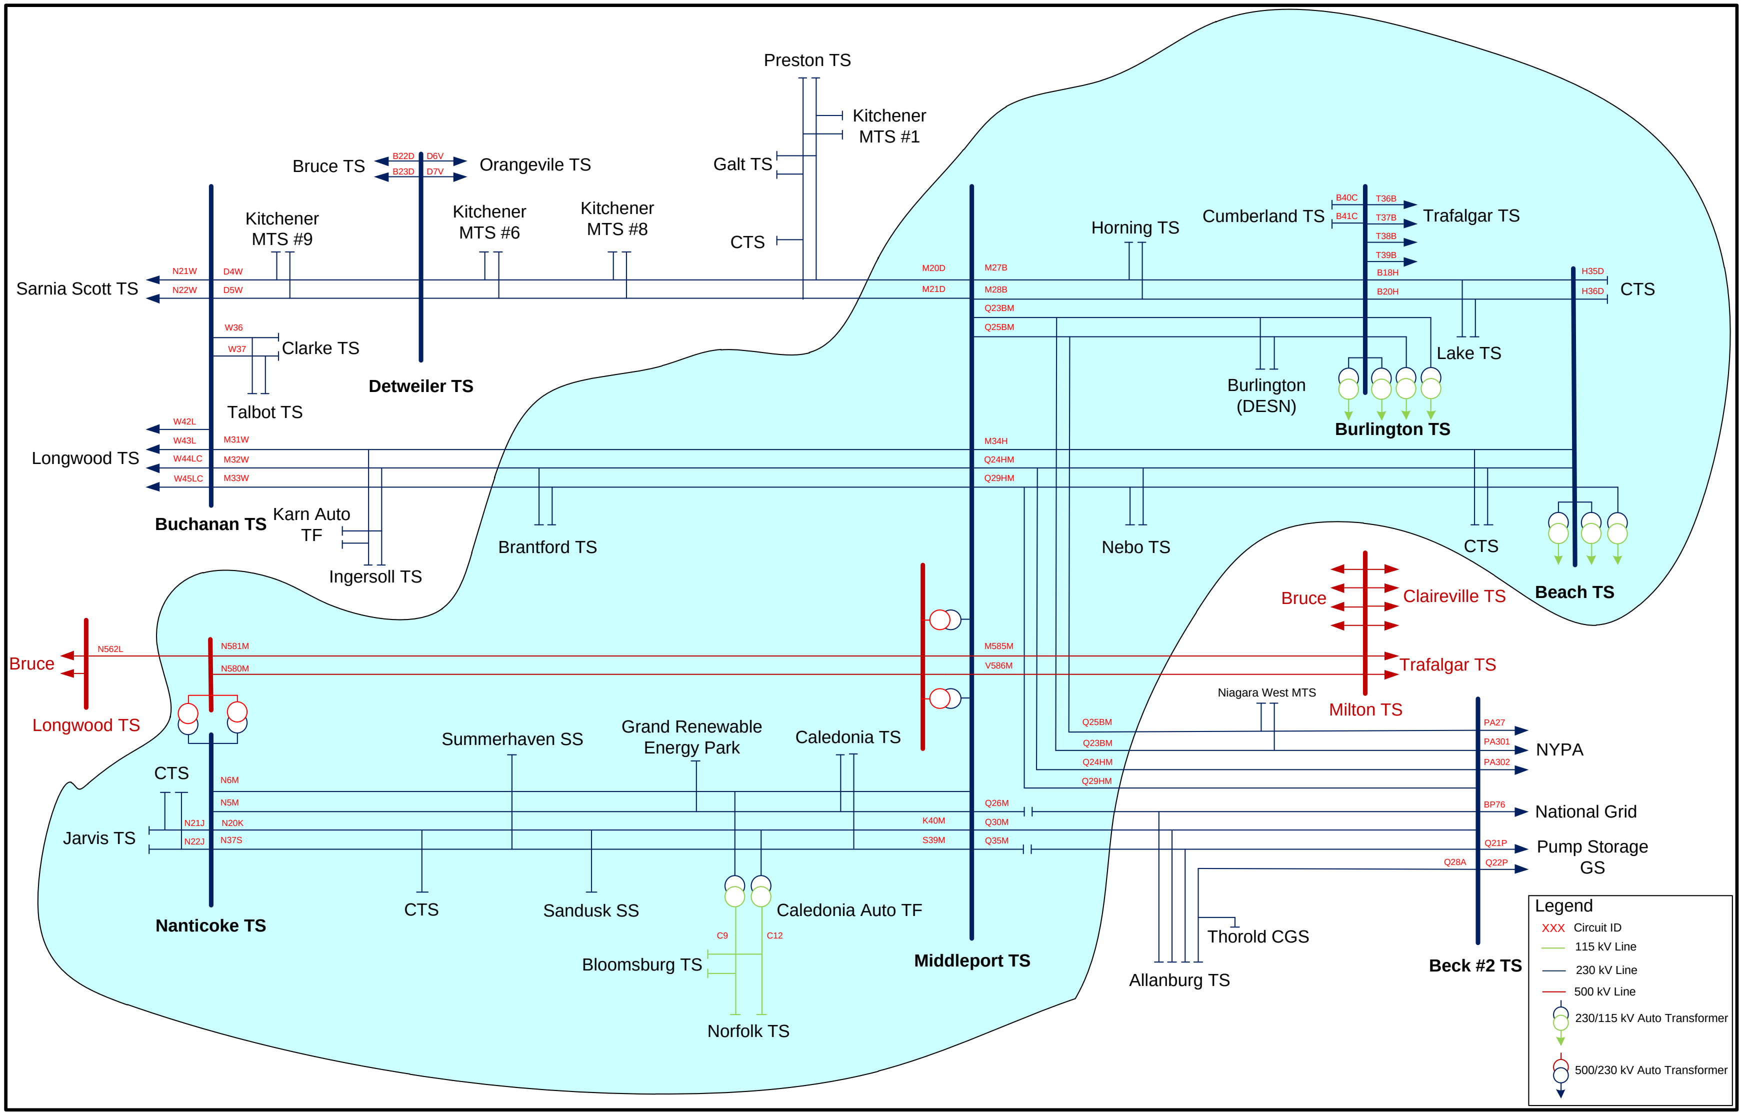

Figure 3-5 Burlington to Nanticoke Region 500 & 230 kV and Caledonia-Norfolk 115 kV Network

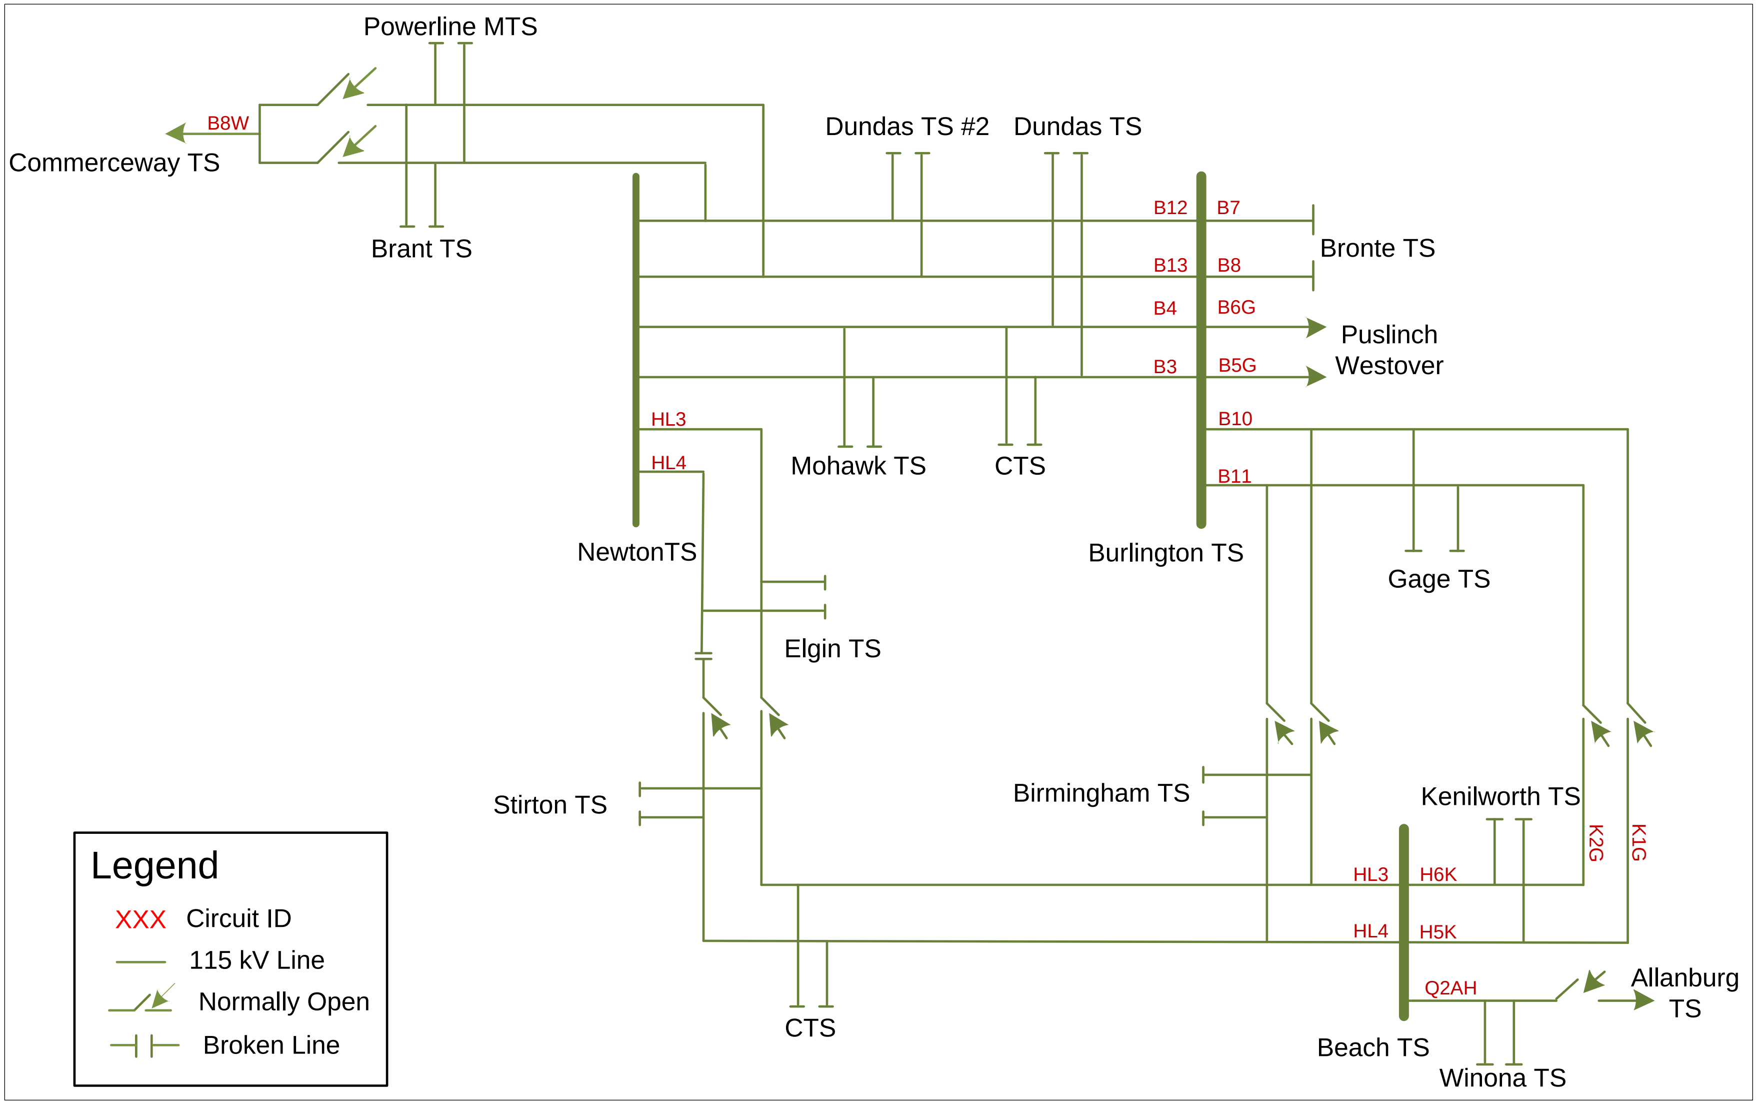

Figure 3-6 115 kV Network Supplied by Burlington TS and Beach TS

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, IN CONSULTATION WITH THE LDCs AND/OR THE IESO, AIMED TO MAINTAIN OR IMPROVE THE RELIABILITY AND ADEQUACY OF SUPPLY IN THE BURLINGTON TO NANTICOKE REGION.

A brief listing of some of the major projects completed over the last ten years are as follows:

- Bronte TS (2008) - added a new low voltage breaker between T5/T6 DESN and T2 DESN units at Bronte TS.
- Burlington TS (2009) - replaced 230 kV/115 kV autotransformer T6 following failure.
- 2nd 115 kV Supply to Norfolk TS and Bloomsburg DS (2009) – Built 12 km of new 115 kV circuit to provide 2nd supply to Norfolk TS and Bloomsburg DS.
- Jarvis TS (2011) and Caledonia TS (2012) – installed LV reactors to reduce short circuit levels below the TSC limits and to allow increased generation connection capability at these stations.
- Nebo TS (2013) – replaced T1/T2 230 kV/ 27.6 kV transformers with larger size standard units and added six new breaker positions to meet customer needs.
- Burlington TS (2016) – installed an additional 230 kV circuit breaker to reduce probability of the simultaneous loss of two autotransformers at this station improving supply reliability to the stations supplied from 115 kV Burlington TS bus.
- Transformer replacement at stations: Bronte TS (2006), Norfolk TS (2009), Birmingham TS (2010), Cumberland TS (2012), Brantford TS (2013), Kenilworth TS (2014), Dundas TS (2015) and Brant TS (2016).
- Feeder Positions – added four new breaker positions at Horning TS (2006) and two new feeder breaker positions at Bronte TS (2008) to meet the customer needs.

[This page is intentionally left blank]

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the Burlington to Nanticoke Region is growing at a slow rate with a decline of industrial loads in the region. Currently, load is forecast to increase at an average annual rate of approximately 0.24% up to 2035. The growth rate varies across the Region – with the highest growth rate of 1.37% in the Brant Sub Region.

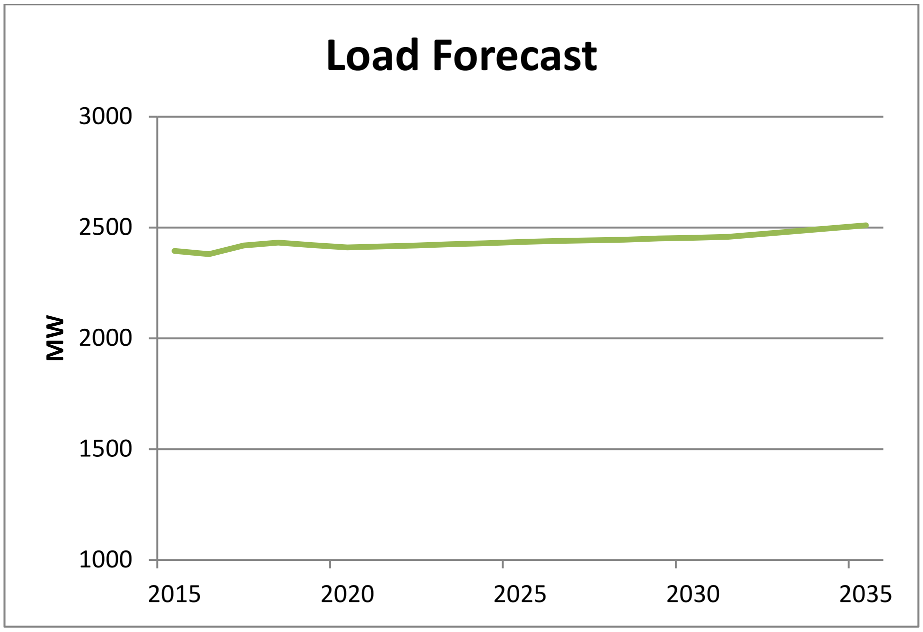

Figure 5-1 Burlington to Nanticoke Region Summer Extreme Weather Peak Forecast

Figure 5-1 shows the Burlington to Nanticoke Region peak summer non-coincident load forecast. This forecast is based on the 2015 extreme weather corrected loads. The non-coincident forecast represents the sum of the individual station's peak load and is used to determine the need for stations and line capacity. Regional non-coincident load forecast for the individual stations in the Burlington to Nanticoke Region is given in Appendix D.

The RIP load forecast was developed as follows:

- Load forecast for stations in the Bronte Sub region was taken from the IESO Bronte Sub- Region IRRP completed on June 30, 2016.
- Load forecast for Brant TS and Powerline MTS in the Brant Sub-Region was prepared by input and discussions with the LDCs recently (2016) as part of detailed planning for Brant switching station.
- Load forecast for the remaining stations was developed using the summer 2015 actual peak load adjusted for extreme weather and applying the station net growth rates provided by the LDCs. The net station loads account for CDM measures and connected DG in the region.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2015-2025.
- All planned facilities listed in Section 4 are assumed to be in-service.
- Where applicable, future industrial loads have been reduced based on historical information.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations in this sub-region is determined by the Hydro One summer 10-Day Limited Time Rating (LTR).
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6. ADEQUACY OF FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE BURLINGTON TO NANTICOKE REGION OVER THE 2015-2025 PERIOD.

Within the current regional planning cycle three regional assessments have been conducted for the Burlington to Nanticoke Region. These studies are:

1) NA Report - Burlington to Nanticoke Region, May 23 , 2014
2) IRRP Report - Brant Sub-Region, April 28, 2015
3) Local Planning (“LP”) Report – Burlington to Nanticoke Region, October 28, 2015
4) IRRP Report - Bronte Sub-Region, June 30, 2016

The NA and IRRP reports identified a number of needs to meet the forecast load demands and EOL asset issues. A review of the loading on the transmission lines and stations in the Burlington to Nanticoke Region was also carried out as part of the RIP report using the latest regional forecast as given in Appendix D. Sections 6.1 to 6.5 present the results of this review. Further description of assessments, alternatives and preferred plan along with status is provided in Section 7.

6.1 500 and 230 kV Transmission Facilities

The 500 kV and most of the 230 kV transmission circuits in the Burlington to Nanticoke Region are classified as part of the Bulk Electricity System (“BES”). They connect the Region to the rest of Ontario’s transmission system. A number of these circuits also serve local area stations within the region and the power flow on them depends on the bulk system transfers as well as local area loads. In addition there are three 230 kV double circuit lines H35D/ H36D, B40C/ B41C and N21J/ N22J that supply only local loads. The circuits supplying local loads in the region are as follows (refer to Figure 3-5):

1. Middleport TS to Burlington TS 230 kV transmission circuits M27B/ M28B - supply Horning TS.
2. Middleport TS to Beck #2 TS to Burlington TS 230 kV transmission circuits Q23BM/ Q25BM /Q24HM/ Q29HM - supply Burlington (DESN) TS, Nebo TS and one customer owned CTS.
3. Middleport TS to Buchanan TS 230 kV transmission circuits M32W/ M33W - supply Brantford TS.
4. Middleport TS to Nanticoke TS 230 kV transmission circuits N5M/ S39M / N20K - supply Caledonia TS and one customer owned CTS.
5. Burlington TS to Beach TS 230 kV transmission circuits B18H/ B20H - supply Lake TS.
6. Nanticoke TS to Jarvis TS 230 kV transmission circuits N21J/ N22J - supply Jarvis TS and one customer owned CTS.
7. Beach TS to one customer owned CTS 230 kV transmission circuits H35D/ H36D.
8. Burlington TS to Cumberland TS 230 kV transmission circuits B40C/ B41C - supply Cumberland TS.

Bulk system planning is conducted by the IESO and is informed by government policy, including policy outlined in the long term energy plan ("LTEP"). Government engagement on the next LTEP is currently underway, with a new LTEP expected to be issued in Q2/Q3 2017. Bulk system needs, options and recommendations for Power System facilities serving this region will be determined by the IESO as part of the implementation plan for the 2017 LTEP.

6.2 230/115 kV Transformation Facilities

Almost half of the Region's load is supplied from the 115 kV transmission systems. The primary source of 115 kV supply is from three 230/115 kV autotransformers at Burlington TS, Beach TS and Caledonia TS.

Table 6-1 summarizes the loading levels for all three 230 /115 kV auto transformers in the Burlington to Nanticoke region.

Table 6-1 Adequacy of 230/115 kV Autotransformer Facilities

Overloaded Facilities	MVA Load Meeting Capability	2015 MVA Loading	Need Date
Burlington TS 230/115 kV autotransformers	912	745	-[1]
Beach TS 230/115 kV autotransformers	582	348	-[1]
Caledonia TS 230/115 kV autotransformer	187	88	-[1]

[1] Adequate over the study period (2015- 2025)

The autotransformers in the Burlington to Nanticoke region are of adequate capacity over the study period (2015-2025). The Needs Assessment identified a stuck breaker scenario at Burlington TS that could result in simultaneous loss of two of the four autotransformers at Burlington TS. This is a low probability scenario under which the loading on the remaining two autotransformers could exceed their short time emergency rating.

However, recently an additional 230 kV breaker has been added to the scheme reducing the possibility of simultaneous loss of two autotransformers at Burlington TS under a single contingency scenario. In addition, installation of the new 230/115 kV autotransformers at Cedar TS and 115 kV switching at Brant TS, to be in-service by 2019, will further reduce loading on the Burlington TS autotransformers.

The loading on the Burlington TS 230/115 kV autotransformers, for the simultaneous loss of two autotransformers, is therefore expected to remain within the short term rating of the two remaining in-service autotransformers at Burlington TS. No further action is required.

6.3 115 kV Transmission Facilities

The 115 kV transmission facilities can be divided in three main sections: Please see Figure 3-5 and 3-6 for the single line diagrams.

1. Burlington 115 kV – has twelve 115 kV circuits B3/B4, B5/B6, B7/B8, B10/B11, B12/B13 and HL3/ HL4. All circuits are adequate over the study period except for sections of the B7/B8 and B12/B13 circuits as given below in Table 6-2. These needs have been identified in the earlier phases of the regional planning process and are being addressed by Hydro One as per the recommendations in respective IRRPs and further discussed in this RIP (Section 7).

   The loading on the limiting sections of 115 kV circuits is summarized below in Table 6-2.

Table 6-2 Limiting Sections of 115 kV Circuits

Line Section	Overloaded Circuit	Reference Section	Capacity (MW)	Contingency	2015 Loading (MW)	Need Date
Palermo Jct. to Bronte TS	B7/ B8	Section 7.1	135	B7	129	2018
Horning Mountain Jct. to Brant TS	B12/B13	Section 7.5	125	B12/B13	119	2019

   The HL3/ HL4 115 kV double circuit cable consist of two sections:
   i. HL3/ HL4 Newton TS to Elgin TS
   ii. HL3/ HL4 Elgin TS to Stirton TS (HL4 is idle)

   These cables provide normal and backup supply to Elgin TS. The supply capacity of 115 kV HL3/ HL4 cables is adequate over the study period (2015-2025).

2. Beach 115 kV– has five 115 kV circuits H5K/ H6K, HL3/ HL4 and Q2AH expected to be adequate over the study period. There are two associated 115 kV double circuit cable sections:
   i. K1G/ K2G Kenilworth TS to Gage TS
   ii. H5K/ H6K Kenilworth TS to Beach TS

   These cables provide normal and backup supply to Kenilworth TS. The supply capacity of Beach 115 kV cables and lines is adequate over the study period (2015-2025).

3. Norfolk Caledonia – has two 115 kV circuits C9 and C12 supplying Norfolk TS and Bloomsburg DS. The need of additional supply capacity for C9/C12 double circuit line was identified during the earlier phases of the regional planning cycle.

   The updated load forecast and further assessment as part of this RIP shows that the combined load of Norfolk TS and Bloomsburg DS will remain below the supply capacity of 87 MW of C9/ C12 line during the study period and no further action is required.

The list of all the 230 kV and 115 kV circuits is given in Appendix A.

6.4 Step-Down Transformation Facilities

There are a total of 31 step-down transmission connected transformer stations in the Burlington to Nanticoke Region. The stations have been grouped based on the geographical area and supply configuration. The station loading in each area and the associated station capacity is provided in Table 6-3 below. The complete list of all the stations in the Burlington to Nanticoke region and their supply circuits is given in Appendix B.

Table 6-3 Adequacy of Step-Down Transformer Stations

Area/Supply	Capacity (MW)	2015 Loading (MW)	Need Date
Brant Sub-Region	403	263	-(2)
Bronte Sub-Region	530	402	-(2)
Greater Hamilton Sub-Region (1)	1919	1108	-(2)
Caledonia Norfolk Sub-Region (1)	351	211	-(2)

(1) Excludes Customer Transformer Stations (CTS)
(2) Adequate over the study period (2015-2025)

Dundas TS has two DESN units T1/T2 and T5/T6. During the earlier phases of the Regional Planning cycle T1/T2 DESN at Dundas TS was found to be loaded over its supply capacity due to unbalanced loading between the two Dundas TS DESNs. The current loading at both DESNs at Dundas TS is within each DESN's supply capacity. Further assessment as part of this RIP based on current forecast confirms that the loads on each of the Dundas TS DESNs will remain within its supply capacity during the study period. No further action is required.

Nebo TS 13.8 kV T3/T4 DESN was also identified as marginally over loaded during an earlier phase of the regional planning cycle. Further assessment as part of this RIP based on updated forecast confirms that the loads on the Nebo TS T3/T4 DESN will remain within its supply capacity during the study period. No further action is required.

6.5 System Reliability and Load Restoration

In case of contingencies on the transmission system, ORTAC provides the load restoration requirements relative to the amount of load affected. Planned system configuration must not exceed 600 MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

a. All loads must be restored within 8 hours.
b. Load interrupted in excess of 150 MW must be restored within 4 hours.
c. Load interrupted in excess of 250 MW must be restored within 30 minutes.

It is expected that all loads can be restored within 8 hours in the Burlington to Nanticoke Region over the study period. None of the transmission circuits in the Burlington to Nanticoke region will be supplying total loads in excess of 250 MW. The following double circuit lines in the Burlington to Nanticoke Region are expected to supply the loads in excess of 150 MW at peak times:

- B12/ B13
- B3/ B4
- H35D/ H36D
- HL3/ HL4
- M32W/ M33W
- Q23BM/ Q25BM
- Q24HM/ Q29HM

Based on the historical performance and reliability data for these circuits in the region, the Working Group recommended that no action is required at this time.

[This page is intentionally left blank]

7. REGIONAL NEEDS & PLANS

THIS SECTION DISCUSSES THE ELECTRICAL INFRASTRUCTURE NEEDS FOR THE BURLINGTON TO NANTICOKE REGION AND SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THESE NEEDS. THESE NEEDS INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE NEEDS ASSESSMENT, SCOPING ASSESSMENT, IRRPS FOR THE BRANT, AND BRONTE SUB-REGIONS, ASSESSMENTS CARRIED OUT IN SECTION 6 AS WELL AS EMERGING NEEDS DUE TO AGING INFRASTRUCTURE AND END OF LIFE ISSUES.

This section outlines and discusses infrastructure needs and plans identified for the Burlington to Nanticoke Region and recommended plans and/or next steps for the near-term (up to 5 years) and the mid-to long-term (beyond 5 years).

It should be noted that this RIP, in addition to advancing the work from the aforementioned IRRPs, also identifies additional needs related to sustainment and end-of-life facilities in the Hamilton area. Built over 50 years ago, the transmission assets in the Hamilton area are some of the oldest installations in the province. At the time of the Burlington to Nanticoke Need Assessment and Scoping Assessment phases, done in 2014, the detailed information on the condition and end-of-life issues related to these assets was not available. As such, a decision was made by the Working Group at that time to not initiate a coordinated planning exercise for the Hamilton subsystem. Since then, through the RIP process, the extent and urgency of the sustainment work in the Hamilton area, and also in Oakville and Brantford, are better known by the Working Group.

This RIP discusses those needs and the projects developed to address those needs. Implementation to address some of these needs is already or nearly underway. The plans presented in this RIP to address new end-of-life needs have been developed by Hydro One and needs also confirmed by the LDC. Further details are being formalized by Hydro One through assessment and consultation with the LDC to develop implementation plans. The plans for Beach TS, Birmingham TS, Gage TS and Kenilworth TS were later reviewed by the IESO as part of an ongoing study for the Hamilton area. However, new near and mid-term needs namely Horning TS, Elgin TS, and Bronte TS were not fully identified earlier in the regional planning process and did not undergo a review by the IESO in the earlier phases due to their scope or project status.

The RIP report also identifies long-term needs associated with the revised and better defined sustainment plan. These needs will be assessed in the next planning cycle. A summary of all of these needs in the near-term (2016-2020) and mid to long-term (beyond 2020) are listed in Table 7-1 and Table 7-2, respectively, along with their in-service date, where applicable. Table 7-1 identifies both the stakeholders involved in each project's development and which formal regional planning process it originated from and provide reference to sub-sections with further details for each of the need. The table also indicates the needs identified after the completion of the NA and SA processes.

Table 7-1 Identified Near-Term Needs in Burlington to Nanticoke Region

No.	Needs	Section	Timing
Projects Developed in Local Planning or an IRRP			
1	115 kV B7/B8 Transmission Line Capacity	7.1	2018
2	115 kV B12/B13 Transmission Line Capacity	7.2	2019
3	Two New Feeders at Dundas TS	7.3	2019
4	Cumberland TS – Power Factor Correction	7.4	TBD
5	Kenilworth TS – Power Factor Correction	7.5	TBD
Projects Developed by HONI & the LDC(s), Reviewed by IESO			
6	Kenilworth TS – EOL transformers & switchgear (1)	7.6	2018
7	Beach TS – EOL T3/T4 DESN Transformers (1)	7.7	2019
8	Gage TS – EOL transformers & switchgear	7.8	2019
9	115 kV B7/B8 – EOL Line Section from Burlington TS to Nelson Jct. (1)	7.9	2020
Projects Developed by HONI & the LDC(s)			
10	115 kV B3/B4 – EOL Line Section from Horning Mountain Jct. to Glanford Jct. (1)	7.10	2018
11	Horning TS – EOL transformers & switchgears (1)	7.11	2018
12	Bronte TS – EOL T5/T6 DESN (1)	7.12	2019
13	Elgin TS – EOL transformers & switchgears	7.13	2019
14	Mohawk TS (T1/T2) – Station Capacity & EOL T1/T2 Transformers	7.14	2019

(1) New needs identified by HONI

The mid- and long-term (2021-2025) electrical infrastructure needs in the Burlington to Nanticoke Region are summarized below in Table 7-2. Where available, a preliminary plan to address that need is provided in the corresponding sub-section.

Table 7-2 Identified Mid- and Long-Term Needs in Burlington to Nanticoke Region

No.	Needs	Section	Timing
1	Birmingham TS EOL Metalclad Switchgears	7.15	2021
2	Dundas TS EOL T1/T2 Switchgear	7.16	2021
3	Newton TS EOL Transformers, Switchgears, Breakers	7.17	2021
4	Brantford TS EOL Switchgear	7.18	2022
5	Lake TS EOL Switchgear	7.18	2022

No.	Needs	Section	Timing
6	Stirton TS EOL Switchgear	7.18	2022
7	Beach TS EOL T7/T8 Auto-transformers and T5/T6 Switchgear	7.19	2025
8	EOL Cables in Hamilton area: H5K/H6K, K1G/K2G, HL3/HL4	7.20	TBD

The needs identified in the Burlington to Nanticoke Region in the above Tables 7-1 and Table 7-2 are further discussed below.

7.1 115 kV Circuit B7/B8 Transmission Line Capacity (Burlington TS to Bronte TS)

7.1.1 Description

Bronte TS is radially supplied by the 115 kV double circuit B7/ B8 line from Burlington TS. The supply capacity of Bronte area is limited to 135 MW due to loading on B7/B8 exceeding its thermal capacity following a loss of either of the circuits starting in 2018. In 2021, the post contingency voltage drop for the loss of either circuit will also exceed the ORTAC limit of 10% at Bronte TS. The load in Bronte area is forecasted to exceed the 135 MW supply limit and reach about 150 MW during the study period.

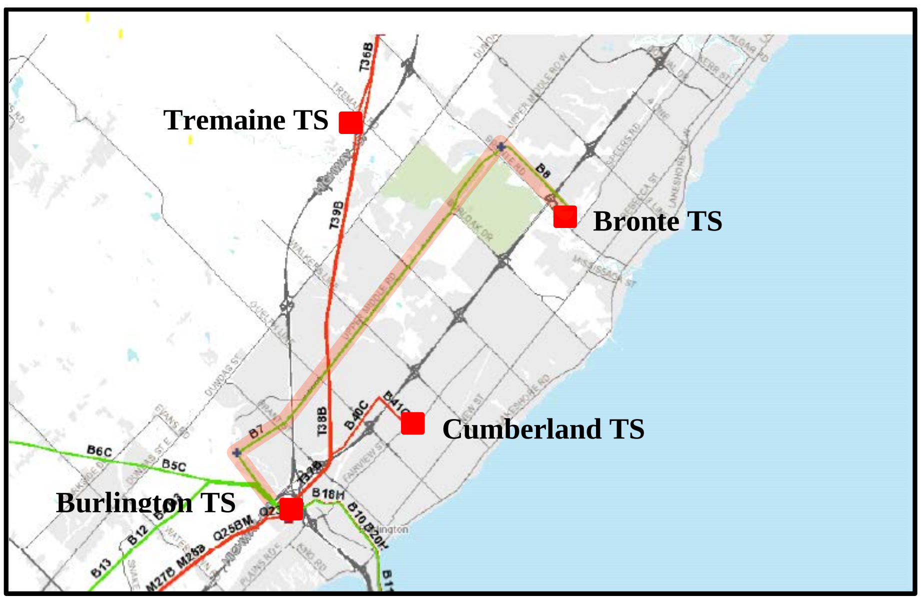

Figure 7-1 Bronte TS Supply Circuits B7/B8

7.1.2 Recommended Plan

The Working Group considered and reviewed different options to provide relief to the 115 kV circuits supplying Bronte TS as part of the Bronte area IRRP. The options included: a) upgrading of transmission system to mitigate the limitation on the 115 kV B7/ B8 circuits and b) Distribution option to transfer load from Bronte TS to neighboring station(s). Upgrading of transmission system was neither economical nor a practical solution.

Consistent with the WG recommendations in the IRRP, the most cost effective and preferred alternative is for LDC(s) to transfer loads from Bronte TS to other neighboring stations and to maintain Bronte TS loading below 135 MW.

Hydro One and the affected LDCs will develop a plan by the end of 2017 for transferring approximately 15 MW of load from Bronte TS to the neighboring station(s). The estimated cost of investments for the distribution load transfer is currently expected to be in the order of $1-3 million.

7.2 115 kV Circuit B12/B13 Transmission Line Capacity (Burlington TS to Brant TS)

7.2.1 Description

Brant TS and Powerline MTS in Brant County are supplied by the 115 kV double circuits B12/B13 line from Burlington TS. The Brant area is experiencing higher growth with a number of new industrial customers planning to connect over the next few years. The combined load of Brant TS and Powerline MTS was 119 MW in summer 2015 and exceeds the 104 MW supply capacity of the B12/B13 line.

7.2.2 Recommended Plan

As per the IRRP recommendations, first phase was to provide additional capacity for the Brant Area's 115 kV supply that included installation of 40 MVAR capacitor banks at Powerline MTS in July 2015. This has increased the line supply capacity to 125 MW.

In addition, the IRRP Working Group considered other options to provide additional 115 kV capacity to supply Brant TS and Powerline MTS to address future load growth over the near-term. The most economical option that was recommended by the WG is to install a three breaker switching station at Brant TS and using the existing backup supply from 115 kV circuit B8W (from Karn TS) as third supply. A single line diagram of the new switching facilities at Brant TS is shown below in Figure 7.2.

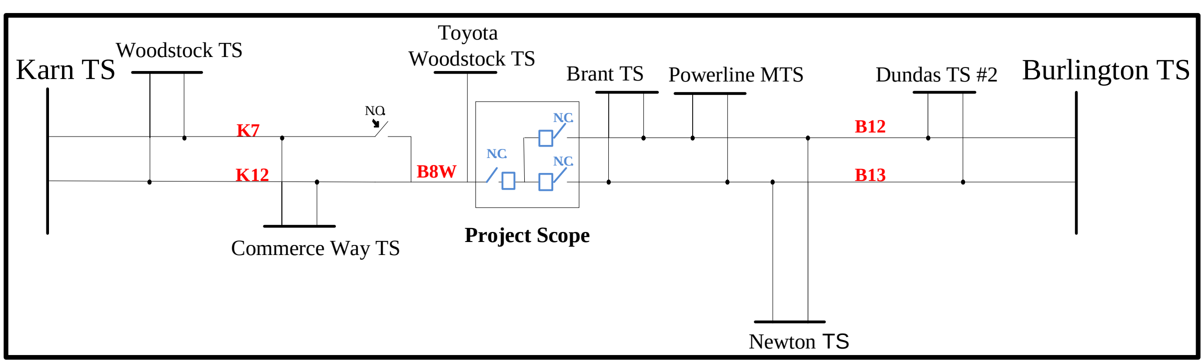

Figure 7-2 Brant Sub-Region Proposed Configuration

Hydro One has initiated detailed engineering work and design. The project is expected to be in-service by spring 2019 and is estimated to cost approximately $12 million. The installation of the switching station will reclassify some of the line connection assets as Network Assets. The project cost will be recoverable from the rate revenue and/or capital contribution from the LDCs in accordance with the TSC.

7.3 Two New Feeders at Dundas TS

7.3.1 Description

Dundas TS has two DESN units T1/T2 and T5/T6 with a total 2015 summer peak load of 148 MW and a station supply capacity of 188 MW. The station capacity is forecasted to be sufficient over and beyond the study period.

A LDC currently supplied from the T1/T2 DESN is planning to transfer load to T5/T6 DESN and supplied from two existing spare breaker positions to meet increased load needs. This will also help in balancing the loads between the two Dundas TS DESNs.

7.3.2 Alternatives, Recommended Plan and Current Status

The following alternatives were considered to address customer’s needs:

- <u>Maintain status quo</u>: This alternative was considered and rejected as it does not address the customer’s needs.
- <u>Transfer customer load to T5/T6 DESN</u>: Move portion of LDC customer loads from T1/T2 DESN to T5/T6 DESN utilizing two spare breaker positions at T5/T6 DESN. This will require reconfiguring of distribution assets by the LDC and will also help improving load balancing between two Dundas TS DESNs.

The preferred plan is to proceed with moving portion of the LDC’s customer load from T1/T2 DESN to T5/T6 DESN utilizing two spare breaker positions. The transfer of load from T1/T2 DESN to T5/T6 DESN is planned to be completed in 2019 at an estimated cost of $8 million.

7.4 Cumberland TS Power Factor Correction

7.4.1 Description

The Cumberland TS supplies up to 123 MW of loads in the city of Burlington. The historical loading data of Cumberland TS indicated that under peak load conditions the power factor at Cumberland TS is lagging slightly below the ORTAC requirement of 0.9.

7.4.2 Recommended Plan and Current Status

The Needs Assessment identified this need and it was recommended that Burlington Hydro to work with their load customers supplied by Cumberland TS and install capacitor banks on distribution system as required to meet the minimum power factor requirements of 0.9.

Burlington Hydro is currently perusing different options to improve the power factor of customer loads supplied by Cumberland TS to meet ORTAC requirement. This issue will be further reviewed during the next regional planning cycle.

7.5 Kenilworth TS Power Factor Correction

7.5.1 Description

There are two supply stations inside Kenilworth TS T1/T4 and T2/T3 supplying about 60 MW of loads in the city of Hamilton. The historical loading data of Kenilworth TS indicated that under peak load conditions the power factor at Kenilworth TS is lagging below the ORTAC requirement of 0.9.

7.5.2 Alternatives and Recommended Plan

The Needs Assessment identified this need and it was recommended that Alectra Utilities to install capacitor bank on distribution system and/or work with load customers supplied by Kenilworth TS to meet ORTAC power factor requirement of 0.9.

Alectra Utilities is currently perusing option on cost and location to install equipment to improve power factor to meet ORTAC requirement. This issue will be further reviewed during the next regional planning cycle.

7.6 Kenilworth TS End of Life Assets

7.6.1 Description

There are two DESN units T1/T4 and T2/T3 inside Kenilworth TS supplying loads in the city of Hamilton and built in 1950's and 1960's respectively. The load at Kenilworth TS is currently about 60 MW. The T1/T4 transformers are rated at 67 MVA each while the T2/T3 transformers are 100MVA and 120 MVA, respectively, which are non-standard as per current standards. Non-standard and obsolete equipment results in complexity with failures and difficulty in getting similar spare equipment along with their installation. The original 120 MVA T2 transformer was replaced with a standard 100 MVA transformer unit in 2014 due to failure. In addition, one of the three metalclad switchgears at Kenilworth TS is presently out of service while the second in-service metalclad switchgear is approaching end of its useful life. As a result, near-term plan is developed to address the failure and EOL issues.

7.6.2 Alternatives and Recommended Plan

The following alternatives are considered to address end of life issue at Kenilworth TS:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and reduce supply reliability to the customers.
- "Like-for-Like" replacement of the assets: This alternative would require maintaining four transformers and the associated three switchgears which is not justifiable based on the load forecast.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring Kenilworth TS. This alternative was considered but is not feasible due to: a) unique electrical characteristics and requirements of industrial costumer load in the area, and b) higher costs associated with reconfigurations and transfer of customer loads.
- Reconfiguration of the station reducing to two supply transformers and two switchgears: This option will reconfigure and adequately downsize the station. In this configuration, station will be reduced from four transformers to only two transformers supplying two switchgears.

The preferred plan is for Hydro One to proceed with the reconfiguration of the station and reduce it to two transformers and two switchgears only. The recently replaced transformer and one of the existing metalclad switchgear will be utilized while one transformer and switchgear will be required to be replaced. The new transformer will be a standard unit similar to T2 that was replaced in 2014. This refurbishment project is currently planned to be completed by the year 2018 at an estimated cost of $19 million.

7.7 Beach TS EOL T3/T4 DESN Transformers

7.7.1 Description

Beach TS has two DESN units T3/T4 and T5/T6 supplying loads in the city of Hamilton and built in 1950's and 1960's respectively. The T3/T4 DESN is supplied by the 115 kV bus while the T5/T6 DESN is supplied from the 230 kV bus at Beach TS. The 115/13.8 kV T3/T4 DESN transformers have been identified by Hydro One approaching the end of their useful life and require replacement. The load at Beach TS T3/T4 DESN is currently about 32 MW and is forecasted to stay at the same level in the foreseeable future.

7.7.2 Alternatives and Recommended Plan

The following alternatives are considered to address Beach TS T3/T4 supply transformer end of life issue:

- Continue to maintain the assets (status quo): This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and reduce supply reliability to the customers.
- "Like-for-Like" replacement of the assets: Replacing existing EOL 115/ 13.8 kV T3/T4 DESN transformers with similarly sized units.

- Reconfigure 115 kV T3/T4 transformers to a 230 kV configuration by replacing the existing non-standard 115/ 13.8 kV (67 MVA + 75 MVA) transformers with standard 100 MVA 230/13.8 kV units.

Keeping the existing supply configuration at 115 kV of T3/T4 transformers at Beach TS is not possible as it does not meet safety clearance requirements. In light of this and the fact that moving the transformer supply configuration from 115 kV to 230 kV bus is similar in cost plus has other long-term advantages, such as the 230 kV supply option will result in reduced loading levels of 230/115 kV Beach TS autotransformers resulting in freeing up capacity and improve supply reliability.

The preferred plan is for Hydro One to proceed with reconfiguring the 115 kV T3/T4 DESN to a 230 kV configuration by replacing the existing non-standard transformers with standard 100 MVA 230/13.8 kV units is the most suitable option. The project is currently underway, and is expected to be completed in 2019. The cost of this investment is currently estimated at about $17 million.

7.8 Gage TS End of Life T3/T4/T5/T6 Transformers and a Switchgear

7.8.1 Description

Gage TS has three DESNs (T3/T4, T5/T6, and T8/T9) predominantly supplying large industrial customer loads in Hamilton. T3/T4 and T5/T6 DESNs were built in the 1940's with each transformer rated at 63 MVA LTR, while T8/T9 DESN was built in 1960's with each transformer rated at 137 MVA LTR. These transformers are non-standard with unique electrical characteristics with high short circuit requirements of the customer. The transformers T3, T4, T5, and T6, as well as T5/T6 DESN at Gage TS have been identified by Hydro One at their EOL and have been previously deferred to better understand customer load requirements. Transformer T5 has failed multiple times and breakers in the T5/T6 DESN have experienced recurring problems. No issues or refurbishment needs have been identified at T8/T9 DESN at this time.

The load at Gage TS has reduced over the years to approximately 48 MW, and is currently expected to stay at this level over the study period. The existing station capacity (of the three DESNs) is about 240 MW. Although there seems to be over-capacity at Gage TS, unique short-circuit and connection requirements of industrial loads at this station limits the feasibility of some of the alternatives/solutions.

7.8.2 Alternatives, Recommended Plan and Current Status

The following alternatives were considered to address end of life issues at Gage TS:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition, safety issues and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.
- "Like-for-Like" replacement of the assets: This alternative would continue maintaining six transformers and the associated three switchgears. This option is extremely costly and cannot be justified since the load has significantly reduced at this station.

- Station/load consolidation: Moving loads to neighboring station(s) and retiring Gage TS. This alternative is not feasible due to: a) unique costumer load requirements (i.e., high short circuit currents are required to operate customer's large arc furnaces and large motors without significant impact to power quality), and b) higher costs associated with reconfigurations of LV cables and transfer of customer loads to other stations.
- Reconfiguration of the station and downsize the station from three DESN to two DESN station: In this option, the station will be reconfigured and downsized from the existing six transformers to four transformers.

The preferred plan is for Hydro One to proceed with the reconfiguration of the station and reduce it from 3 DESNs to 2 DESNs. Under this plan, T3/T4 and T5/T6 DESNs will be replaced by a single T10/T11 DESN with two 100 MVA standard units and switchgear currently supplied by T5/T6 transformers will also be replaced. This option will also provide future flexibility to eliminate T8/T9 DESN when it approached EOL.

The refurbishment of Gage TS is currently expected to be completed in 2019 at an estimated cost of $37 million.

7.9 115 kV Circuit B7/B8 End of Life Section (Burlington TS to Nelson Junction)

7.9.1 Description

The 115 kV double circuit line B7/B8 line supplies about 130 MW of Burlington and Oakville area loads through Bronte TS. The line section from Burlington TS to Nelson junction (about 2.3 km) was built in 1920's. Hydro One has identified that the conductor on this line section from Burlington TS to Nelson junction has reached end of useful life.

7.9.2 Alternatives and Recommended Plan

The following alternatives are considered to address 115 kV B7/B8 end of life line section from Burlington TS to Nelson junction:

- Maintain status quo: This alternative was considered and rejected as it does not address the EOL issue, risk of failures resulting in poor supply reliability and would result in increased maintenance expenses.
- Refurbishment of EOL line section: Refurbish 2.3 km of EOL line conductor section of B7/B8 line section.

The preferred plan is to proceed with the refurbishment of the 115 kV B7/ B8 line section from Burlington TS to Nelson junction supplying Bronte TS using similar ACSR conductor. The refurbishment work is planned to be completed by the year 2020 and estimated to cost approximately $2 million.

7.10 115 kV B3/B4 End of Life Line Section (Horning Mountain Jct. to Glanford Jct.)

7.10.1 Description

The 115 kV B3/B4 line supplies Hamilton area loads through Dundas TS (T1/T2 DESN), a CTS and Mohawk TS. Mohawk TS is supplied from B3/B4 line through about 16 km long line-tap supplying about 84 MW of load. A section of this line tap has a solid copper conductor from Horning Mountain Jct. to Glanford Jct. which is approximately 100 year old and has reached end of useful life.

7.10.2 Alternatives and Recommended Plan

The following alternatives are considered to address the above need:

- Continue to maintain the assets (status quo): This alternative was considered and rejected as it does not address the frequent failure, increased maintenance expenses and poor supply reliability.
- Refurbishment of EOL line section: Replace EOL copper conductor with 605 kcmil ACSR conductor Mohawk TS line tap section.

The preferred plan is for Hydro One to replace this EOL copper conductor with 605 kcmil ACSR from Horning Mountain Jct. to Glanford Jct. supplying Mohawk TS. This work is currently planned to be completed by 2018 at an estimated cost of $8 million.

7.11 Horning TS End of Life Assets

7.11.1 Description

Horning TS is a 230/13.8 kV DESN station built in 1967 and supplies Alectra Utilities loads in the Hamilton area. It has two station supply transformers of 100 MVA each supplying load through its two metalclad switchgears. Recent equipment failures in 2016 due to aging low voltage switchgear have adversely impacted supply to customers in the Hamilton area along with safe operations.

In addition, both the transformers and both low voltage switchgears at Horning TS are approaching end of expected useful life and have been identified by Hydro One for replacement. The load at Horning TS is currently about 70 MW and is forecasted to stay at the same level during the study period.

7.11.2 Alternatives and Recommended Plan

The following alternatives are considered to address Horning TS end of life issue:

- Continue to maintain the assets (status quo): This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and reduce supply reliability to the customers.

- "Like-for-Like" replacement of the assets: This alternative would continue maintaining current station configuration and only replace existing transformers will similar units and refurbish both metalclad switchgears.

The preferred plan is for Hydro One to proceed with Like-for-Like replacements replacing supply transformers with similar 100 MVA units and refurbishing EOL low voltage metalclad switchgears. The new replaced transformers and refurbished switchgear will provide sufficient capacity to serve the load over the study period. The project is currently underway, and is expected to be completed in 2018. The cost of this investment is estimated to be about $37 million.

7.12 Bronte TS End of Life T5/T6 DESN

7.12.1 Description

Bronte TS was placed in service in 1963 and is radially supplied from Burlington TS via 115 kV B7/ B8 circuits. The total load at Bronte TS is currently about 129 MW and is forecasted to stay at about 135 MW with load transfers as proposed in section 7.1.

There are three transformers, T2 (single transformer configuration), and T5/T6 DESN (83 MVA), at Bronte TS supplying loads in the cities of Oakville and Burlington. Transformer T2 was replaced in 2006 and the T5/T6 DESN transformers at Bronte TS and LV switchgear is approaching end of expected useful life. Hydro One has identified that these transformers require replacement.

7.12.2 Alternatives and Recommended Plan

The following alternatives are considered to address end of life Bronte TS T5/T6 DESN refurbishment:

- Continue to maintain the assets (status quo): This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and reduce supply reliability to the customers.
- "Like-for-Like" replacement of the assets: Replacing existing EOL 115/ 27.6 kV T5/T6 DESN transformers with similar size standard units and refurbish switchgear.

The preferred plan is for Hydro One to proceed with Like-for-Like replacement. This will include replacing existing 83 MVA T5/T6 transformers with similar units and refurbishing associated switchgear. This investment is estimated to be approximately $34 million with planned in-service of 2019.

7.13 Elgin TS End of Life Assets

7.13.1 Description

Elgin TS has two DESNs (T1/T2 and T3/T4) built in 1960's supplying loads in the city of Hamilton through three switchgears. The current load at Elgin TS is approximately 85 MW, and is currently expected to stay at this level over the study period.

The T1/T2 transformers are 75 MVA units while the T3/T4 units are non-standard 33 MVA units. All existing four transformers (T1, T2, T3, and T4) and three switchgears at Elgin TS have been identified by Hydro One as approaching end of their useful life. This need was identified in the Needs Assessment phase.

7.13.2 Alternatives, Recommended Plan and Current Status

The following alternatives were considered to address end of life issues at Elgin TS:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition, safety issues and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.
- "Like-for-Like" replacement of the assets: This alternative would continue maintaining four transformers and the associated three switchgears. This option is extremely costly and cannot be justified with load forecast not showing any growth at this station.
- Reconfiguration and downsize the station from two DESNs to one DESN station: In this option, the station will be reconfigured and downsized from the existing four transformers to two transformers.

The preferred plan is for Hydro One to proceed with the reconfiguration of the station and reduce it to two transformers and two switchgears only. Under this plan, T1/T2 and T3/T4 DESNs will be replaced by a single T5/T6 DESN with two 100 MVA standard units and four new switchgears. This will maintain adequate supply capacity to the loads through the four new switchgears. The cost of this investment is expected to be $58 million with a planned in service of 2019.

7.14 Mohawk TS Station Supply Capacity & End of Life T1/T2 Transformers

7.14.1 Description

Mohawk TS is a 115/13.8 kV step down transformer station supplied from 115 kV circuit B3/B4 from Burlington TS supplying loads in the city of Hamilton. The station supply capacity is limited to 80 MW by the LTR of transformers. The 2015 summer peak load was 84 MW and the station is marginally over its supply limits during peak load periods. In addition, transformers at Mohawk TS are over 50 years old and condition assessment has identified Mohawk TS transformers approaching end of their useful life.

7.14.2 Alternatives and Recommended Plan

The following alternatives were considered to address Mohawk TS end of life transformer issue:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition, poor supply reliability and would result in increased maintenance expenses. In addition option will not address the capacity needs at the station,
- Transformer replacement: Replacing the existing non-standard (67 MVA) end of life transformers with new standard (75 MVA) units.

The preferred plan is for Hydro One to proceed with the replacement of existing nonstandard supply transformers at Mohawk TS with the standard 75 MVA units. This will address the issue of: a) EOL transformers, b) replace non-standard equipment with standard units, and c) will provide sufficient station supply capacity. In the interim, Alectra Utilities will manage the overloads (under contingency) by distribution loads transfers. The transformer replacement project is currently expected to be in service by 2019 at an estimated cost of $14 million.

7.15 Birmingham TS End of Life Switchgear

7.15.1 Description

Birmingham TS is located in the city of Hamilton having two DESN units T1/T2 and T3/T4 of 75 MVA each. Both the DESNs at Birmingham TS can supply a total load of about 185 MVA (LTR). The Birmingham TS currently supplies a large industrial customer with unique connection requirements. The load at Birmingham TS is forecasted at about 75 MW.

At this time transformers and/or other HV equipment at this station has not been identified as EOL over the study period. However, two 13.8 kV LV metalclad switchgears are at EOL and have been identified by Hydro One for refurbishment.

7.15.2 Recommended Plan

The two end of life 13.8 kV LV end of life metalclad switchgears at Birmingham TS are required to be replaced to meet the unique connection needs of the customer at this station. Not replacing the end of life switchgears will increase the risk of failure due to asset condition and adversely impact supply to a large industrial customer. Currently Hydro One plans to complete this by 2021. This need will be further reviewed in the next regional planning cycle.

7.16 Dundas TS End of Life Switchgear

7.16.1 Description

Dundas TS has two DESN units T1/T2 and T5/T6 with a total 2015 summer peak load of 148 MW and station capacity of 188 MW. The station capacity is forecasted to be sufficient over and beyond the study period. The T1/T2 transformers at Dundas TS have recently been replaced in 2015. The Dundas TS T1/T2 27.6 kV MV switchgear has been identified by Hydro One at end of life requiring refurbishment.

7.16.2 Alternatives and Recommended Plan

Hydro One has identified MV 27.6 kV T1/T2 switchgear at Dundas TS at end of life requiring refurbishment. Keeping status quo not refurbishing this switchgear will increase the risk of failure due to asset condition reducing supply reliability to the customers and would result in increased maintenance expenses.

The refurbishment switchgear is currently planned by Hydro One to be completed by 2021. This need is recommended to be further reviewed in the next regional planning cycle.

7.17 Newton TS End of Life Transformers and Switchgear

7.17.1 Description

Newton TS is a 115 kV/ 13.8 kV DESN station having transformers built in 1956 and supplies Alectra Utilities loads in the city of Hamilton. It has two station supply transformer of 67 MVA each supplying loads through its 13.8 kV switchyards. The customer load at the station is about 50 MW and is forecasted to stay at the same level in the foreseeable future. Hydro One in initial assessment has identified that both transformers and switchgear requiring refurbishment. The scope of refurbishment is subject to final asset condition assessment of Newton TS to be completed in 2017.

7.17.2 Alternatives and Recommended Plan

The following alternatives are considered to address Newton TS end of life asset issue:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance cost.
- Replacement of the assets: Replace existing EOL non-standard transformers with similarly sized units and refurbish switchgear to current standards.

The current plan is to refurbish Newton TS with new equipment built to current standards including two 75 MVA units replacing existing 67 MVA transformers and LV switchgear. This is the preferred alternative since it addresses the needs at Newton TS and maintaining station's operability and reliability of supply. This refurbishment work at Newton TS is planned by Hydro One to be completed by 2021. This need is recommended to be further reviewed in the next regional planning cycle.

7.18 Mid-Term End of Life LV Switchyard Refurbishment

7.18.1 Description

Hydro One has identified the LV switchyards reaching end-of-life by 2022 and need to be refurbished at the following stations:

1. Brantford TS
2. Lake TS
3. Stirton TS

7.18.2 Recommended Plan

The Working Group is recommending that these needs to be further reviewed in the next regional planning cycle.

7.19 Beach TS End of Life T7/T8 Autotransformers and T5/T6 DESN LV Switchgear

7.19.1 Description

Beach TS is a major switching and transformer station in East Hamilton. Station facilities include a 230 kV switchyard, three 230/115 kV autotransformers (T1/T7/T8), a 115 kV switchyard, a 230/13.8 kV DESN T5/T6 and a 115/13.8 kV DESN T3/T4.

Hydro One has determined that autotransformers T7 and T8 and the T5/T6 DESN LV Metalclad switchgear are expected to reach end of life by 2025 and will need to be replaced.

7.19.2 Recommended Plan

The Working Group is recommending that this need be further reviewed in the next regional planning cycle.

7.20 End of Life Cables in Hamilton Area: HL3/HL4, K1G/K2G, H5K/H6K

Underground cables in Hamilton area (listed below) are expected to be approaching end-of-life over the next 10 years or so.

- 115 kV H5K/H6K Cable (Beach TS to Kenilworth TS)
- 115 kV K1G/K2G Cable (Kenilworth TS to Gage TS)
- 115 kV HL3/HL4 Cable (Newton TS to Elgin TS)
- 115 kV HL3/HL4 Cable (Elgin TS to Stirton TS)

In light that replacement of the high voltage underground cables can be complicated, affect upstream transmission system and expensive requires alternative/s to be developed and assessed ahead of time. The WG has recommended further review of the cable replacement needs and development of a tentative plan in the next regional planning cycle.

[This page is intentionally left blank]

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN (RIP) REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE BURLINGTON TO NANTICOKE REGION.

A list and summary of all the needs and/or plans in the near-term (2016-2020) and mid to long term (beyond 2020) is provided below in Table 8-1 and Table 8-2, respectively, along with their in-service date and estimated cost, where applicable. Where available, preliminary plans to address the mid- to long-term needs were also provided.

Table 8-1 Near-Term Needs/Plans in Burlington to Nanticoke Region

No.	Needs	Plans	Status	I/S Date	Cost ($M)
Projects Developed in Local Planning or an IRRP					
1	115 kV B7/B8 Transmission Line Capacity	Bronte TS: Load Transfer	Planning	2018	1-3
2	115 kV B12/B13 Transmission Line Capacity	Install Brant Switching Station	Planning	2019	12
3	Two New Feeders at Dundas TS	Dundas TS: Load Transfer	Planning	2019	8
4	Cumberland TS – Power Factor Correction	LDC is developing distribution option	Planning	TBD	-
5	Kenilworth TS – Power Factor Correction	LDC is developing distribution option	Planning	TBD	-
Projects Developed by HONI & the LDC(s), Reviewed by IESO					
6	Kenilworth TS EOL transformers & switchgear (1)	Reconfigure from 2 DESNs to single DESN	Planning	2018	19
7	Beach TS – EOL T3/T4 DESN Transformers (1)	Replace Beach TS T3/T4 DESN Transformers	Committed	2019	17
8	Gage TS – EOL transformers & switchgear	Gage TS: Reduce from 3 DESNs to 2 DESNs	Planning	2019	37
9	115 kV B7/B8 – EOL Line Section from Burlington TS to Nelson Jct. (1)	Refurbish the EOL B7/B8 line section	Planning	2020	2
Projects Developed by HONI & the LDC(s)					
10	115 kV B3/B4 – EOL Line Section from Horning Mountain Jct. to Glanford Jct. (1)	Refurbish the EOL B3/B4 line section conductor	Planning	2018	8
11	Horning TS EOL transformers & switchgears (1)	Replace EOL transformers & refurbish switchgears	Committed	2018	37

No.	Needs	Plans	Status	I/S Date	Cost ($M)
12	Bronte TS – EOL T5/T6 DESN [1]	Replace EOL transformers & refurbish switchgear	Committed	2019	34
13	Elgin TS – EOL transformers & switchgears	Replace transformers and reduce 2 DESNs to 1 DESN	Committed	2019	58
14	Mohawk TS (T1/T2) – Station Capacity and EOL T1/T2 Transformers	Mohawk TS Transformers Replacement	Committed	2019	14

(1) New needs identified by HONI

Table 8-2 Mid- and Long-Term Needs/Plans in Burlington to Nanticoke Region

No.	Needs/Plans	Planned I/S Date	Cost ($M)
1	Birmingham TS: 2 Metal Clad Switchgear Refurbishment [1]	2021	14
2	Dundas TS: T1/T2 switchyard refurbishment	2021	10
3	Newton TS: Station Refurbishment	2021	36
4	LV Switchgear Refurbishment at Brantford TS, Lake TS and Stirton TS	2022	46
5	Beach TS: Replace EOL T7/T8 Autotransformers and refurbish T5/T6 DESN switchgear	2025	60
6	EOL 115 kV Cables: - H5K/ H6K - K1G/ K2G - HL3/ HL4	TBD [2]	TBD [2]

(1) Preliminarily reviewed by HONI, LDC and the IESO
(2) To Be Decided

It is the recommendation of RIP Working Group:

a) Hydro One will continue to implement the committed and near-term projects for addressing the above needs as discussed in this report, while keeping the Working Group apprised of project status, and
b) The RIP recommends that an expedited Needs Assessment report should be developed to list these already identified needs in the mid and long term or any new needs to be followed by Scoping Assessment, led by the IESO for further assessment under the Burlington to Nanticoke regional planning Working Group.

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GREATER OTTAWA REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro Ottawa Limited
- Hydro Hawkesbury Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Hydro One Networks Inc. (Transmission)
- Ottawa River Power Corporation

This RIP provides a consolidated summary of needs and recommended plans for both the Ottawa Area Sub-Region and Outer Ottawa Area Sub-Region that make up the Greater Ottawa Region for the near term (up to 5 years) and the mid-term (5 to 10 years). No long term needs and associated plans (10 to 20 years) have been identified.

This RIP is the final phase of the regional planning process and it follows the completion of the Ottawa Sub-Region's Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015 and the Outer Ottawa Area Sub-Region's Needs Assessment ("NA") Study by Hydro One in July 2014.

The major infrastructure investments planned for the Greater Ottawa Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the Table below.

No.	Project	I/S date	Cost
1	Almonte TS: addition of breaker to sectionalize line M29C	November 2015	$4.7M
2	Russell TS and Riverdale TS: construction of feeder ties to allow extra load transfers	2017-2020	$2.0M
3	Lisgar TS: replacement of transformers T1 and T2	December 2017	$13.9M
4	Hawthorne TS: replacement of autotransformers T5 and T6	May 2018	$15.7M
5	Overbrook TS: replacement of transformers T3 and T4	June 2018	$1.1M(1)
6	115kV Circuit A6R: additional tap to off load Circuit A4K	June 2019	$9-11M
7	Hawthorne TS: replacement of transformers T7 and T8 and add one 44kV feeder position	October 2019	$1.1M(2)
8	King Edward TS: Replace Transformer T4	June 2021	$12M

(1) The transformers are at end of life and are being replaced as part of Hydro One sustainment program. The cost shown here represents the incremental cost of installing the next larger size units.
(2) Incremental cost for larger transformer only.

The IRRP study had also identified the need for additional 230/115 kV autotransformation capacity at Merivale TS and provision for a supply for a new station in the southwest area. The options to address these needs are still being studied by the Working Group and as part of the IESO community engagement activities. The Working Group expects to finalize recommendation to address these needs by summer 2016.

Investments to address the other mid-term needs, for cases where a decision is not required until 2020, will be reviewed and finalized in the next regional planning cycle.

No long term needs were identified at this time. As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GREATER OTTAWA REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the joint study carried out by Hydro One, Hydro Ottawa Limited ("Hydro Ottawa"), Hydro Hawkesbury Inc. ("Hydro Hawkesbury"), Ottawa River Power Corporation ("ORPC") and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The Greater Ottawa Region covers the municipalities bordering the Ottawa River from Arnprior in the West to Hawkesbury in the East and North of Highway 43. At the center of this region is the City of Ottawa. Electrical supply to the Region is provided from fifty-two 230 kV and 115 kV step-down transformer stations. The summer 2015 area load of the Region was about 1800 MW. The boundaries of the Region are shown in Figure 1-1 below.

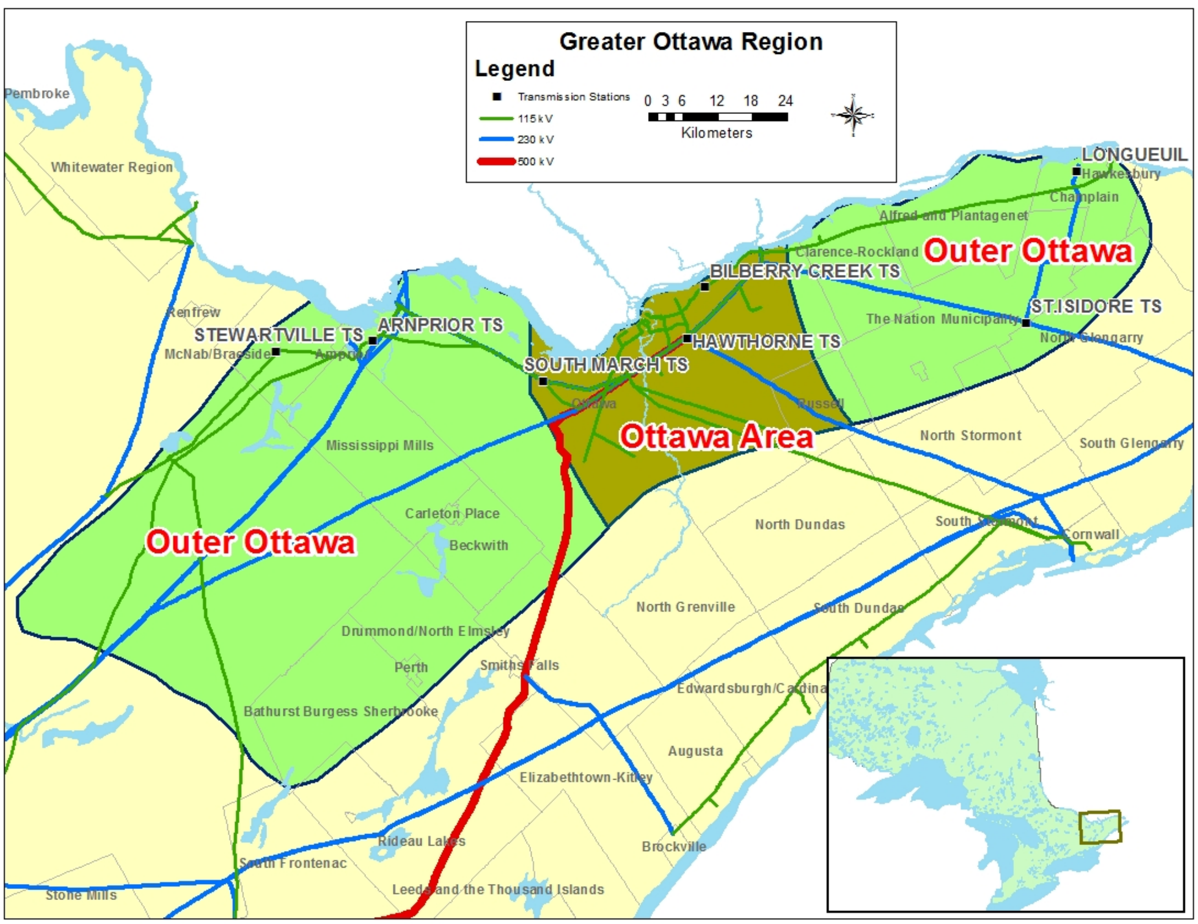

Figure 1-1 Greater Ottawa Region

1.1 Scope and Objectives

This RIP report examines the needs in the Greater Ottawa Region. Its objectives are to: identify new supply needs that may have emerged since previous planning phases (e.g. Needs Assessment, Local Plan, and/or Integrated Regional Resource Plan); assess and develop a wires plans to address these needs; provide the status of wires planning currently underway or completed for specific needs; and identify investments in transmission and distribution facilities or both that should be developed and implemented to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan).
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated information.
- Develop a plan to address any longer term needs identified by the Working Group

The IRRP or RIP Working Group did not identify any long term needs at this time. If required, further assessment will be undertaken in the next planning cycle because adequate time is available to plan for required facilities.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the region.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

[1] Also referred to as Needs Screening.

a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region. Since the Ottawa Sub-Region was in transition to the new regional planning process, the IESO led IRRP engagement for this sub-region was initiated after the completion of the IRRP.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

The regional planning process specifies a 20 year planning assessment period for the IRRP. No specific period has been specified for the RIP. The RIP focuses on the wires options and, given the forecast uncertainty and the fact that adequate time is available to identify and plan new wire facilities in subsequent planning cycles, a study period of 10 years is considered adequate for the RIP. The only exception would be the case where major regional transmission is required for an area with limited or no transmission facilities. In these cases the RIP would review and assess longer term needs if identified in the IRRP.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA, SA, and LP phases of regional planning.
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

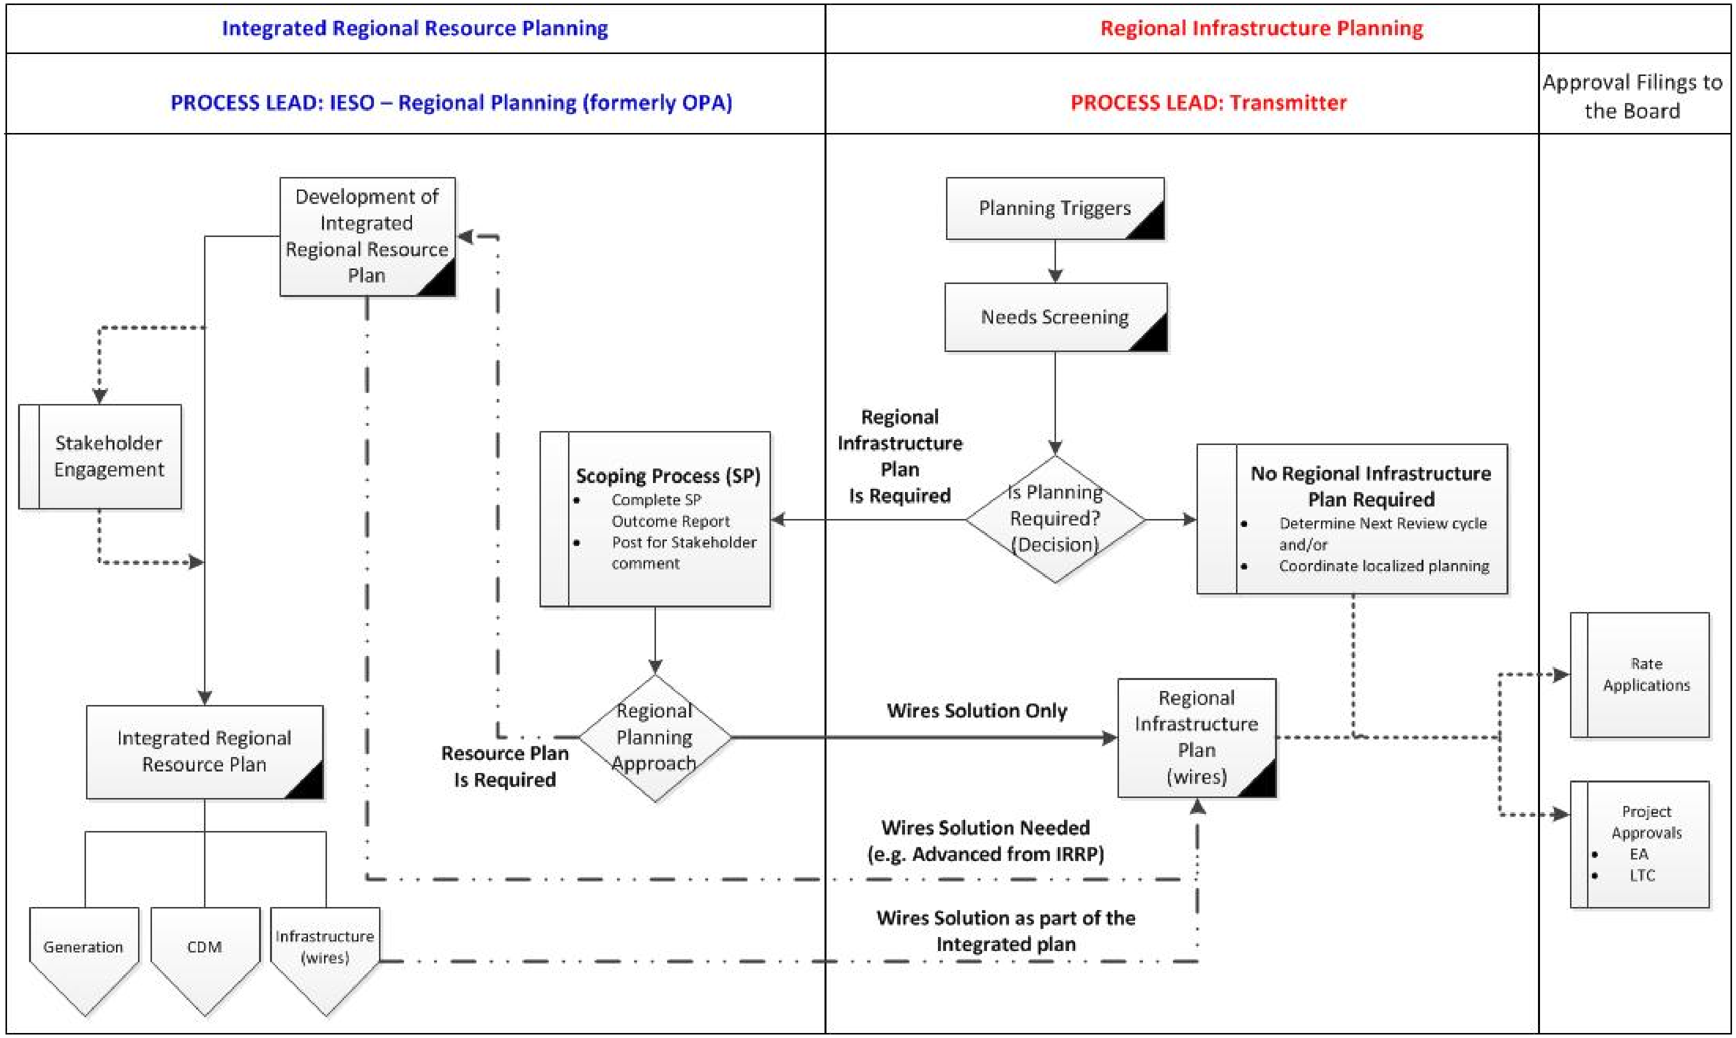

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

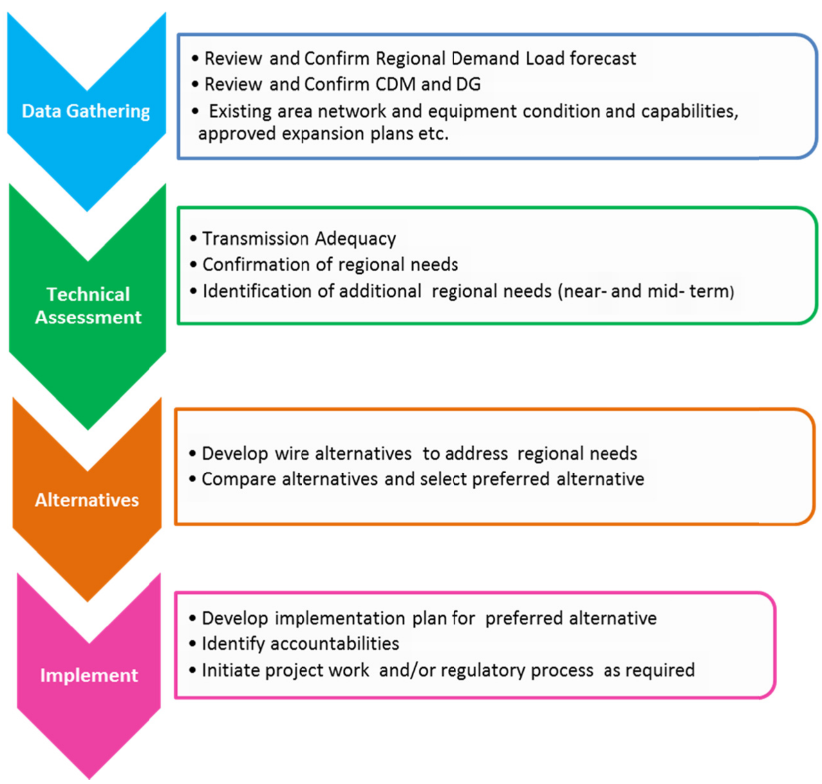

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GREATER OTTAWA REGION COVERS THE MUNICIPALITIES BORDERING THE OTTAWA RIVER FROM ARNPRIOR IN THE WEST TO HAWKESBURY IN THE EAST AND NORTH OF HIGHWAY 43. AT THE CENTER OF THIS REGION IS THE CITY OF OTTAWA (SEE FIGURE 3-1). ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FIFTY-TWO 230 KV AND 115 KV STEP-DOWN TRANSFORMER STATIONS. THE 2015 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 1840 MW.

Bulk electrical supply to the Greater Ottawa Region is provided through the 500/230 kV Hawthorne TS and a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. The area has been divided into two sub-regions as shown in Figure 1-1 and described below:

- The Ottawa Sub-Region comprises primarily the City of Ottawa. It is supplied by two 230/115 kV autotransformer stations (Hawthorne TS and Merivale TS, eight 230 kV and thirty-three 115 kV transformer stations stepping down to a lower voltage. Local generation in the area consists of the 74 MW Ottawa Health Science Non-Utility Generator ("NUG") located near the downtown area and connected to the 115 kV network. The Ottawa Sub-Region is shown in Figure 3-1 below.

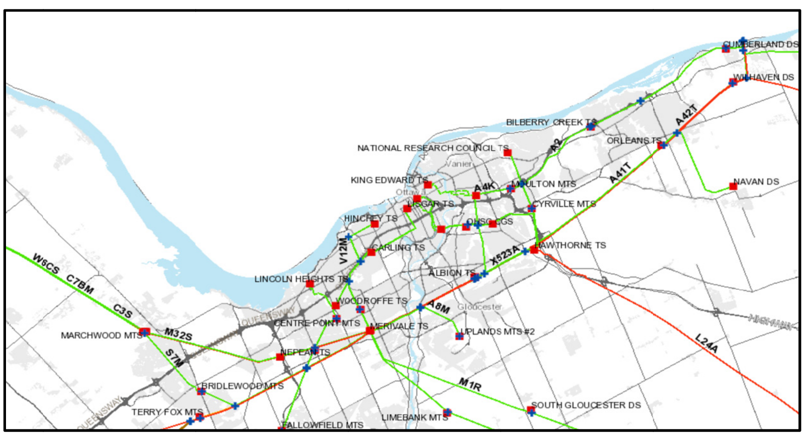

Figure 3-1 Ottawa Sub-Region

Hydro Ottawa is the main LDC that serves the electricity demand for the City of Ottawa. Hydro One Distribution supplies load in the outlying areas of the sub-region. Both Hydro Ottawa and Hydro One Distribution receive power at the step-down transformer stations and distribute it to the end users, i.e. industrial, commercial and residential customers.

- The Outer Ottawa Sub-Region covers the remaining area of the Greater Ottawa Region. The eastern area (shown in Figure 3-2) is served by three 230 and five 115 kV step-down transformer stations. Hydro One Distribution and Hydro Hawkesbury are the LDCs in the area that distribute power from the stations to the end use customers. It also includes a large industrial customer, Ivaco Rolling Mills, in L'Orignal, Ontario.

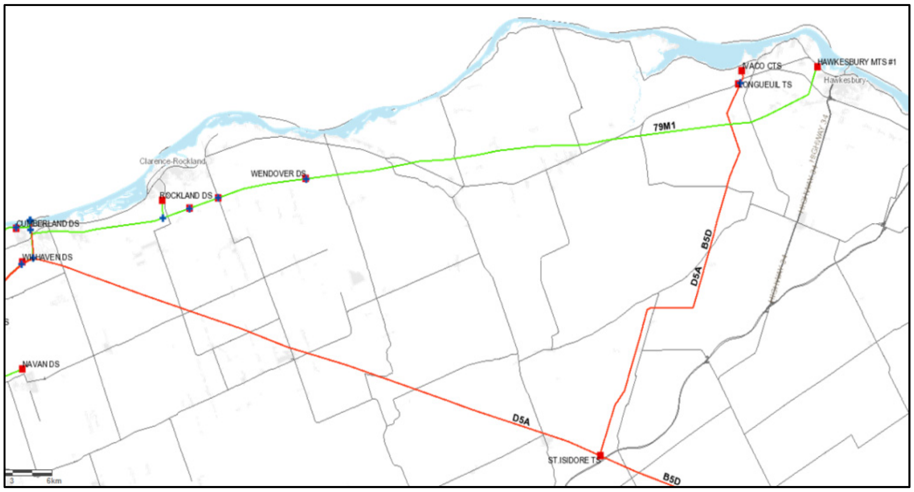

Figure 3-2 Outer Ottawa Sub-Region, Eastern Area

The western area of the Outer Ottawa Sub-Region is served by one 230 kV and two 115 kV step-down transformer stations. Hydro One Distribution is the LDC that supplies end use customers for these stations. The area includes the following generating stations: Barrett Chute GS, Chats Falls GS and Stewartville GS with a peak generation capacity of about 450 MW.

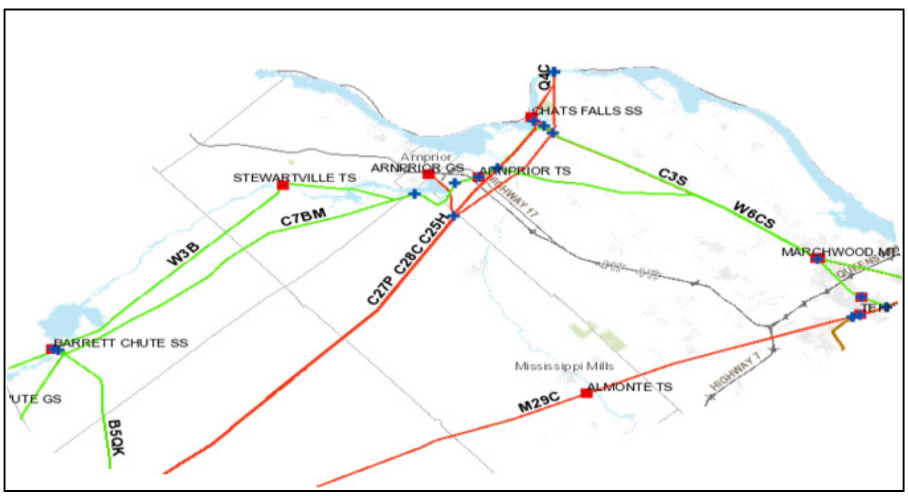

Figure 3-3 Outer Ottawa, Western Area

An electrical single line diagram for the Greater Ottawa Region facilities is shown in Figure 3-4.

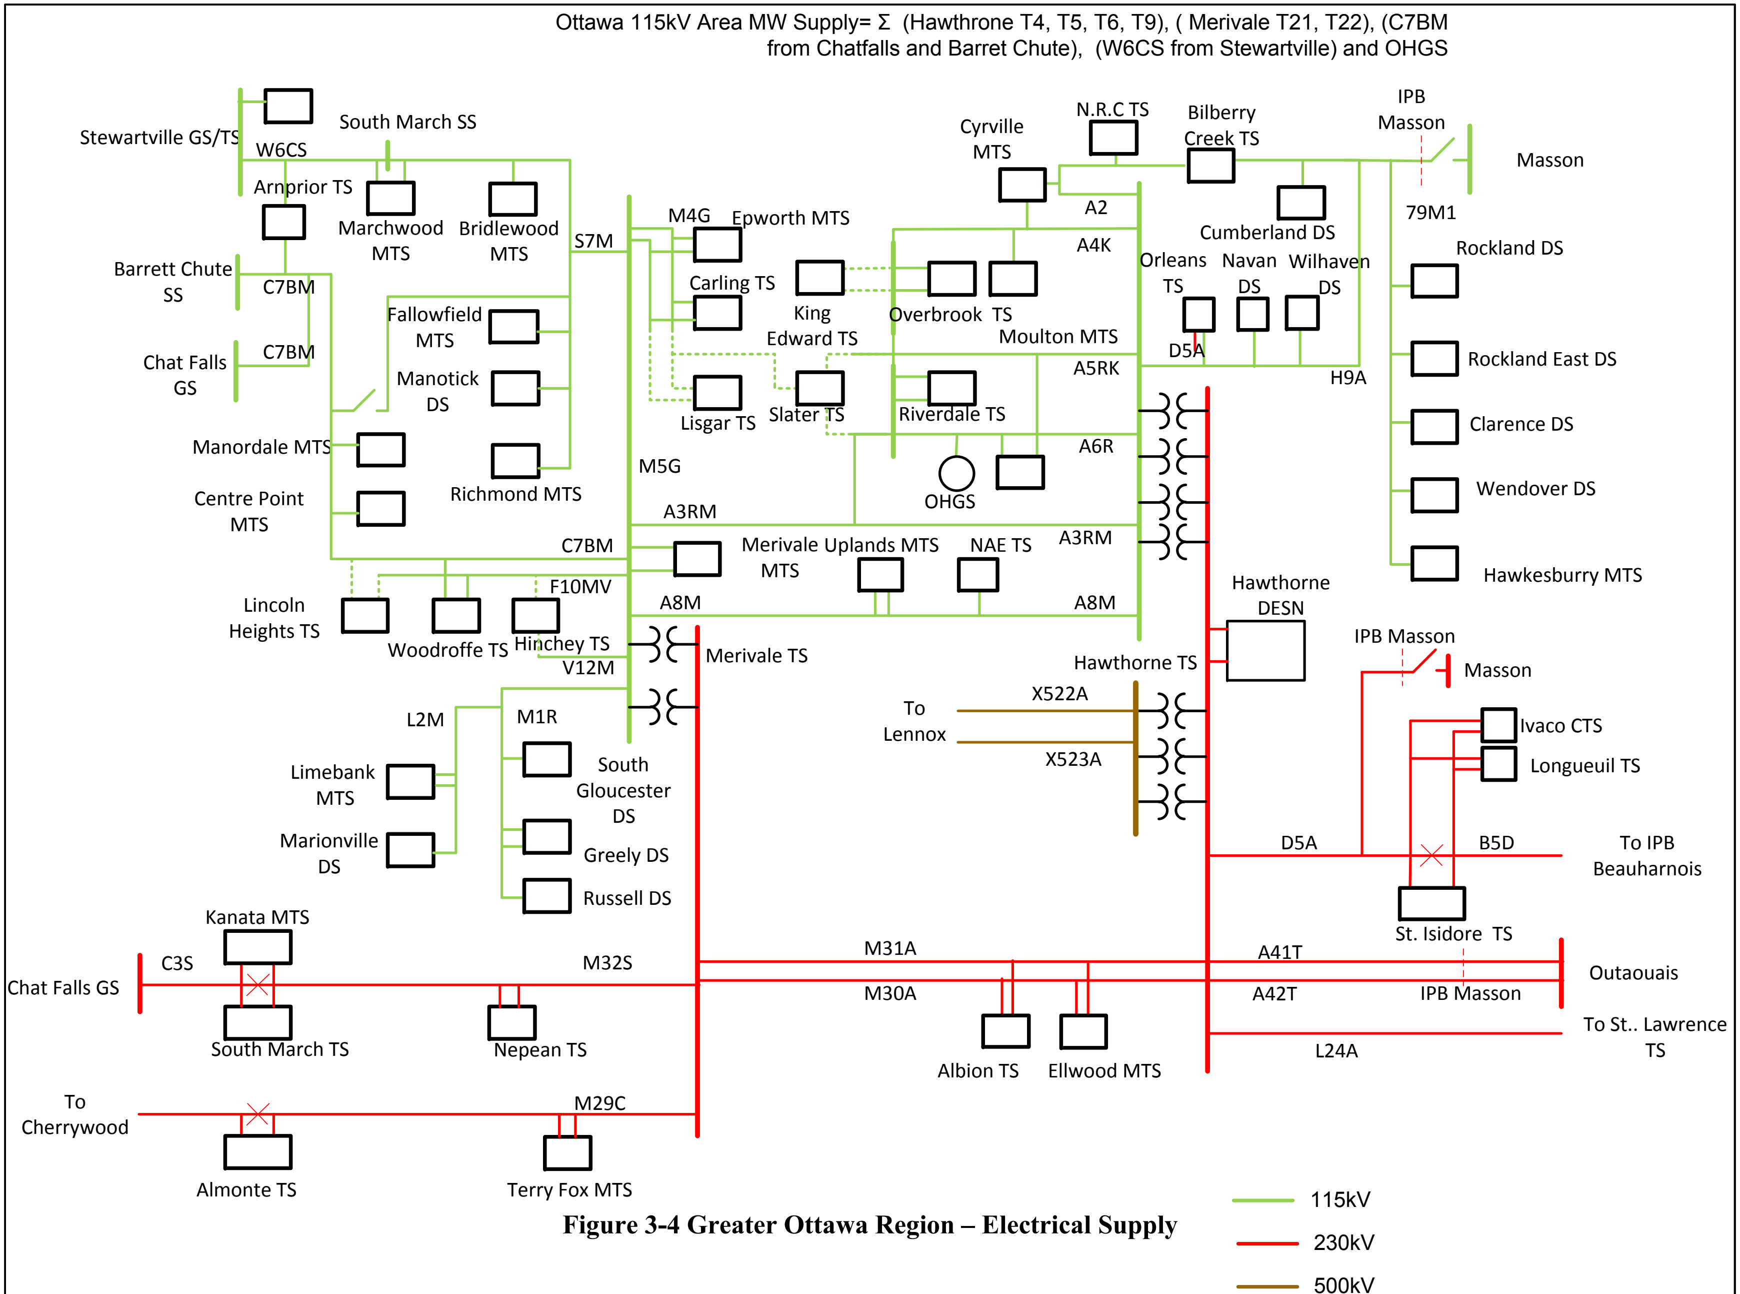

Figure 3-4 Greater Ottawa Region – Electrical Supply

21

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GREATER OTTAWA REGION IN GENERAL AND THE CITY OF OTTAWA IN PARTICULAR.

These projects were identified as a result of either: joint Hydro One, IESO and Hydro Ottawa planning studies to meet the needs of Hydro Ottawa or Hydro One Distribution; and/or, to meet provincial government policies. A brief listing of the completed projects over the last 10 years is given below:

- Hawthorne TS x Gamble Junction double circuit 230 kV Overhead line (2008) – the single 115 kV circuit H9A was rebuilt as a two circuit 230 kV tower line with increased capacity. Connect Cyrville MTS (2008) – connected new Hydro Ottawa owned Cyrville TS to 115 kV circuits A4K and A2.
- Hawthorne TS x Outaouais TS double circuit 230 kV line (2009) – built to provide up to 1250MW of transfer capability with Hydro Quebec as part of the new HVDC interconnection.
- Connect Ellwood MTS (2012) – connected new Hydro Ottawa owned Ellwood TS to 230 kV circuits M30A and M31A.
- Connect Terry Fox MTS (2013) – connected new Hydro Ottawa owned Terry Fox MTS to 230 kV circuit M29C.
- Hawthorne TS 115 kV switchyard Upgrade (2014) – replaced 115 kV breakers with inadequate short circuit capability with new breakers of higher short circuit capability. This work improved system reliability by allowing 115kV switchyards to be operated with bus tie closed. This work also facilitated incorporation of DG in the Ottawa area.
- Build new Orleans TS (2015) – built a new step-down transformer station in East Ottawa supplied from 230 kV circuit D5A and 115 kV circuits H9A. This station will provide additional load meeting capability to meet Hydro One Distribution and Hydro Ottawa requirements. It will also provide improved reliability for Hydro One Distribution customers in the Orleans-Cumberland area.
- Hinchey TS (2015) – Connect idle winding of transformer T1/T2 to new Hydro Ottawa metalclad switchgear.

The following projects are currently underway:

- Add 230 kV inline breaker on 230 kV circuit M29C at Almonte TS (2015) – to improve reliability of supply for Almonte TS and Terry Fox MTS.
- Replace 45/75 MVA, 115/13.2 kV step down transformers with new 60/100 MVA, 115/13.2 kV at Overbrook TS (2017) – the existing transformers are at end-of-life and the new replacement transformers have a higher rated capacity and will provide additional load meeting capability.

- Replace 225 MVA, 230/115 kV autotransformers T5 and T6 at Hawthorne TS with new 250 MVA, 230/115 kV autotransformers (2018) – the existing transformers have inadequate capacity and were identified and recommended for replacement during the IRRP phase for the Ottawa Sub-Region [1].
- Replace 50/83 MVA, 230/44 kV step down transformers with new 75/125 MVA, 230/44 kV units at Hawthorne TS (2019) – the existing transformers are at end-of-life and the new replacement transformers have a higher rated capacity and will provide additional load meeting capability.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the Greater Ottawa Area is forecast to increase at an average rate of approximately 2.25% annually up to 2020, at 0.96% between 2020 and 2025 and at 0.45% beyond 2025. The growth rate varies across the Region with most of the growth concentrated in the Ottawa Sub-region.

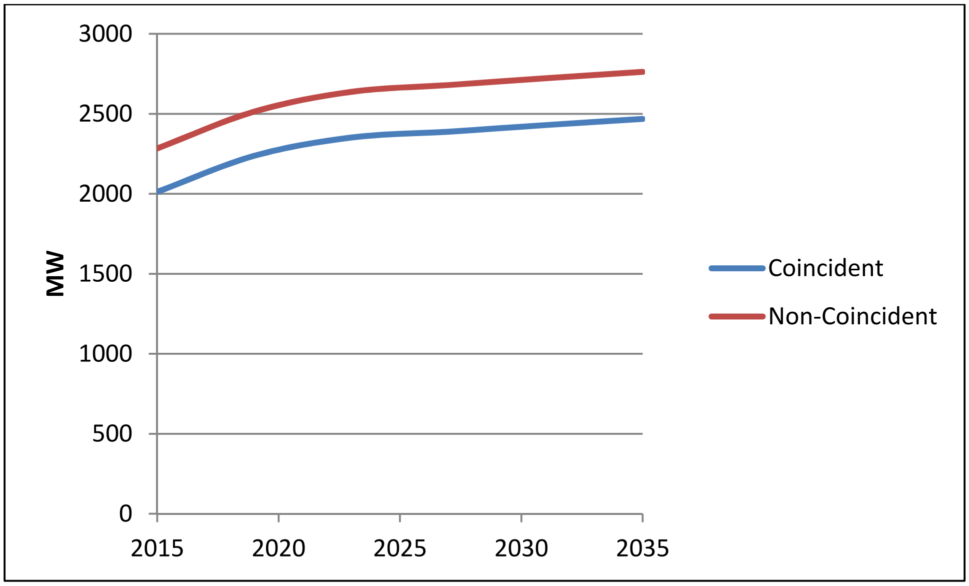

Figure 5-1 Greater Ottawa Region Summer Extreme Weather Peak Forecast

Figure 5-1 shows the Greater Ottawa Region extreme weather peak summer coincident and non-coincident load forecast. The coincident forecast represents the sum of the peak load at the time of the region's peak load and represents loads that would be seen by the autotransformer stations and is used to determine the need for additional auto-transformation capacity. The non-coincident forecast represents the sum of the individual stations peak load and is used to determine the need for stations and line capacity. Coincident and Non-coincident load forecasts for the individual stations in the Greater Ottawa Region are given in Appendix A.

The RIP load forecast was developed as follows:

- RIP Working Group participants confirmed that the load forecast, CDM, and DG information used in the IESO's 2015 IRRP for the Ottawa Sub-Region[1] and Hydro One's 2014 NA [2] was still valid and there were no changes.
- The station coincident loads used in the RIP are as given in the IRRP for Ottawa Sub-Region and NA for the Outer Ottawa Sub-Region. The coincident loading is used for evaluating the adequacy of bulk transmission circuits and the 230/115kV autotransformers.

- Stations non-coincident load forecast was developed using the summer 2015 actual peak load adjusted for extreme weather and applying the station net growth rates as identified in the IRRP and NA. The non-coincident forecast is used to determine adequacy of station capacity. The net growth rate accounts for CDM measures and connected DG. Details on the CDM and connected DG are provided in the IRRP [1] and NA for Ottawa Sub-Region [2] and are not repeated here.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP Assessments is 2015-2025.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this Sub-Region is determined by the summer 10-Day Limited Time Rating (LTR).
- Adequacy assessment is conducted as per ORTAC.

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2015-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE GREATER OTTAWA REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM. NO LONG TERM NEEDS HAVE BEEN IDENTIFIED.

Within the current regional planning cycle two regional assessments have been conducted for the Greater Ottawa Region. The April 2015 Ottawa Sub-Region IRRP report [1] was prepared by the IESO in conjunction with Hydro One and Hydro Ottawa. The July 2014 Outer Ottawa Sub-Region NA report [2] was prepared by Hydro One and considered the remainder of the Greater Ottawa region.

The IRRP [1] and NA [2] planning assessments identified a number of regional needs to meet the area forecast load demand over the near to mid-term between 2015 and 2025. These regional needs are summarized in Table 6.1 and include needs for which work is already underway and/or being addressed by an LP study. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

A review of the loading on the transmission lines and stations in the Greater Ottawa Region was also carried out as part of the RIP report. Sections 6.1 to 6.3 present the results of this review. Additional needs identified as a result of the review are also listed in Table 6-1.

Table 6-1 Near and Mid-Term Regional Needs

Type	Section	Needs	Timing(4)
Needs identified in IRRP [1] and NA [2]			
230/115kV Transformation Capacity	7.1	Hawthorne TS T5 and T6 – LTR(1) exceeded	2018(2)
	7.2.1	Merivale TS T22 - LTR(1) exceeded	2019
Transmission Circuit Capacity	7.2.2	S7M Circuit – Capacity	2019 and 2026
	7.3	A4K Circuit - Capacity	2019(2)
Station Capacity	7.4	Center 115kV Area - Capacity	2017-2021(3)
	7.5	Hawthorne TS T7 and T8 – LTR(1) exceeded	2019
	7.2.2	South West Area - Capacity	2020
	7.6	Bilberry Creek TS - Refurbishment	2023
Supply Security, Reliability and Restoration	7.7	Almonte TS/Terry Fox MTS - Reliability	2015
	7.8	Orleans TS - Reliability	No plan recommended(5)
	7.9	B5D+D5A Circuits – Restoration	No plan recommended(5)
	7.10	Load Loss for S7M Contingency	No plan recommended(5)
Voltage Regulation	7.11	79M1 Circuit – Voltage Regulation	2023
	7.12	Stewartville TS – Voltage Regulation	No plan recommended(5)
	7.13	Almonte TS/Terry Fox MTS –Voltage Regulation	No plan recommended(5)
	7.14	Almonte TS – Low Power Factor	No plan recommended(5)
Additional Needs identified in RIP			
	7.2.1	Merivale TS T22 and Hawthorne TS T9 – Continuous ratings exceeded	2024/25
	7.4.2.4	King Edward TS – Capacity	2021

(1) LTR – Limited time ratings to accommodate emergency loading for a short time under contingency conditions
(2) Projects have been initiated.
(3) Miscellaneous stations. Some are already in execution.
(4) Timing shows the proposed in service date for project underway, and the need date for the projects not yet started.
(5) Review did not recommend plan for mitigation. Please see the need details in Section 7.

6.1 500 and 230 kV Transmission Facilities

All 500 kV and 230 kV transmission circuits in the Greater Ottawa Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of Ontario's transmission system and to the Hydro Quebec transmission system. A number of these circuits also serve local area stations within the region and the power flow on them depends on the bulk system transfers as well as local area loads. These circuits are as follows (refer to Figure 3-4):

1. Hawthorne TS to Merivale TS 230 kV transmission circuits M30A/M31A – supply Albion TS and Ellwood TS.
2. Hawthorne TS to Cornwall 230 kV transmission circuits D5A/B5D/B31L – supply Orleans TS, St. Isidore TS and Longueuil TS. Also connects to Hydro Quebec at Beauharnois Station and to Lievre Power at Masson GS.
3. Merivale TS to Chats Falls 230 kV transmission circuits M32S/C3S – supply Nepean TS, South March TS and Kanata MTS
4. Merivale TS x Cherrywood TS 230 kV transmission circuits E29C/E34M (M29C) – supply Terry Fox MTS and Almonte TS.

Based on current forecast station loadings and bulk transfers, the M30A/M31A circuits will require reinforcement by 2020. The M30A/M31A upgrade will be addressed by Hydro One based on the recommendation stemming from an IESO Bulk System Planning study [6]. All other 230 kV circuits are expected to be adequate over the study period.

6.2 230/115 kV Transformation Facilities

Almost sixty percent of the Region load is supplied from the 115 kV transmission system. The primary source of 115 kV supply is from 230/115 kV autotransformers at Hawthorne TS and Merivale TS. Additional support is provided from 115 kV generation at Barrett Chute GS, Stewartville GS, part of Chats Falls GS, and the Ottawa Health Science NUG and the Ottawa River generation at Chaudière. Support from DG and CDM was considered as part of the load forecast.

Table 6-2 summarizes the results of the adequacy studies and gives the need dates for reinforcement of the 230/115 kV autotransformer facilities at Hawthorne TS and Merivale TS. Assuming no change in the system configuration, the forecasted loading will result in the Limited Time Rating ("LTR") of the Merivale autotransformer being exceeded by 2019 and the continuous rating of the Merivale and Hawthorne autotransformers by 2024/25.

The need dates are sensitive to the availability of hydraulic generation from Barrett Chute GS, Stewartville GS and Chats Falls GS and are based on 98% dependable generation availability as per ORTAC criteria. This corresponds to about 18 MW of available generation. A higher level of generator output from these stations would defer the need dates.

The need dates assume that the Hawthorne TS 225 MVA, 230/115 kV autotransformers T5 and T6 have been replaced with new 250 MVA units. The T5 and T6 replacement work is underway and is therefore not identified in the table below.

Table 6-2 Adequacy of 230/115 kV Autotransformer Facilities

Overloaded Facilities	2015 MVA Loading	MVA Load Meeting Capability	Limiting Contingency	Need Date
Merivale TS 230/115kV autotransformer T22	261	312[1]	T21	2019
Merivale TS 230/115kV autotransformer T21	182	250	[2]	2024
Hawthorne TS 230/115kV autotransformer T9	189	250	[2]	2025

[1] Limited time rating exceeded.

[2] Continuous rating exceeded with all elements in service based on existing system configuration

6.3 115 kV Transmission Facilities

The Greater Ottawa Region 115 kV transmission facilities can be divided in five main sections: Please see Figure 3-4 for the single line diagram.

1. Hawthorne 115 kV Center – has four circuits A3RM, A4K, A5RK and A6R. Reinforcement is required for the A4K circuit as a loss of the A5RK circuit would result in the loading exceeding the rating on the A4K circuit between Hawthorne TS and Moulton MTS (for details see Section 7.3).
2. Hawthorne 115 kV East – has two circuits A2 and H9A/79M1. These are expected to be adequate over the study period.
3. Merivale 115 kV Center – has two circuits M4G and M5G. These are expected to be adequate over the study period.
4. Merivale 115 kV West – has five circuits C7BM, F10MV, S7M, V12M and W6CS. Upgrading is required of the S7M tap to Fallowfield TS since forecasted loading will exceed circuit continuous rating (for details see section 7.4)
5. Merivale 115 kV South – has two circuits L2M and M1R. These circuits are adequate for the study period.

The loading on the limiting sections is summarized in Table 6-3.

Table 6-3 Adequacy of 115 kV Circuits

Corridor	Section	Overloaded Circuit	Rating (A)	Contingency	2015 Loading (A)	Need Date
1. Hawthorne TS x Blackburn Jct. x Overbrook TS	Hawthorne TS x Moulton TS	A4K	1070	A5RK	1006	2017
4. S7M tap to Fallowfield MTS	STR R14-R15 x Fallowfield Jct.(2)	S7M	590	All facilities in-service(1)	278	2024

(1) Continuous rating exceeded.
(2) Please see Figure 7-4.

6.4 Step-Down Transformation Facilities

There are a total of fifty-two step-down transmission connected transformer stations in the Greater Ottawa Region. The stations have been grouped based on the geographical area and supply configuration. The non-coincident station loading in each area and the associated station capacity and need date for relief is provided in Table 6-4 below. As shown areas requiring additional transformation capacity are the Center 115kV area, the South West 115kV area and the South 115kV area. Table 6-5 shows the non-coincident station loads for all areas which are adequate over the 2015-2025 study period. Details of the areas and associated stations are given in Appendix B.

Table 6-4 Adequacy of Step-Down Transformer Stations - Areas Requiring Relief

Area/Supply	Capacity (MW)	2015 Loading (MW)	Need Date
Center 115	569(1)	516	2018
South West 115	70	60	2019
South 115	182	151	2024

(1) With Overbrook TS 45/75 MVA transformers replaced with larger 60/100 MVA units.

Table 6-5 Adequacy of Step-Down Transformer Stations – Areas Adequate

Area/Supply	Capacity (MW)	2015 Loading (MW)	2025 Loading (MW)
East 115	340	231	229
West 115	504	351	425
Center 230/13.2kV	147	121	126
Center 230/44kV	153[(1)]	103	136
West 230	397	382	389
Outer East 115	80	56	62
Outer West 115	106	83	96
Outer East 230	149[(2)]	92	90
Outer West 230	100	48	45

(1) With Hawthorne TS 50/83 MVA transformers replaced with larger 75/125 MVA size units.

(2) Includes Longueuil TS and St Isidore TS load.

7. REGIONAL PLANS

This section discusses needs, presents wires alternatives and the current preferred wires solution for addressing the electrical supply needs for the Greater Ottawa Region. These needs are listed in table 6-1 and include needs previously identified in the IRRP for the Ottawa Sub-Region [1] and the NA for the Outer Ottawa Sub-Region [2] as well as the adequacy assessment carried out as part of the current RIP report.

7.1 Hawthorne Autotransformer T5 and T6

7.1.1 Description

Hawthorne TS is a major supply point for the city of Ottawa (Figure 7 -1). The station has four 230kV/115 kV autotransformers. Two of these autotransformers, T5 and T6, have lower ratings, with 225 MVA continuous and 256 MVA LTR, respectively. Under contingency conditions, i.e. one of the autotransformers out of service, the ratings of these two autotransformers are exceeded and this limits the supply to the 115 kV network from the 230 kV system. As the load continues to grow on the 115 kV network, this limitation needs to be addressed. This had been identified as a near term need in the Ottawa Sub-Region IRRP [1] and was included in the Ontario Power Authority's ("OPA", now part of IESO) June 2014 letter to Hydro One [5].

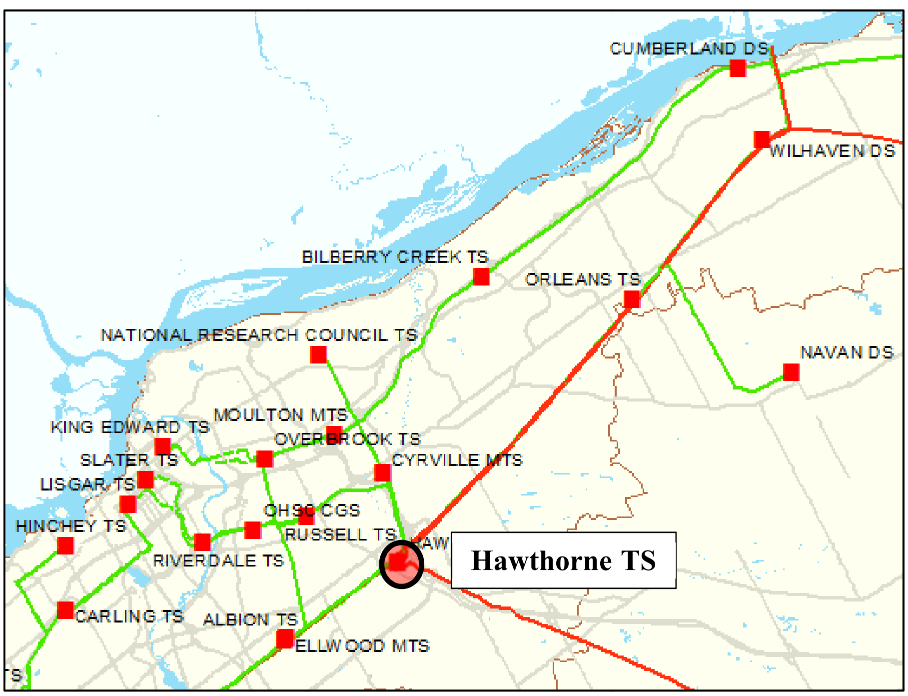

Figure 7-1 Hawthorne TS

7.1.2 Recommended Plan and Current Status

Hydro One has established a project to replace autotransformers T5 and T6 with new higher rated autotransformers. These autotransformers will have an LTR of at least 350 MVA. This investment will provide additional capacity and meet the needs of the area. It is expected that the project will be completed in 2018.

The cost of this project is expected to be $15.7 million. The project will be a transmission pool investment as the autotransformers provide supply to all customers in the Greater Ottawa Region.

7.2 Autotransformation Capacity and South West Area Station Capacity

7.2.1 Merivale TS Autotransformers T21 and T22/Hawthorne Autotransformer T9

Merivale TS has two 230 kV/115 kV autotransformers with an LTR station capacity of 312 MVA. The station is supplied from Hawthorne TS and from generators located west of Ottawa, along the Ottawa River and the Madawaska River. Merivale TS is shown in Figure 7-2.

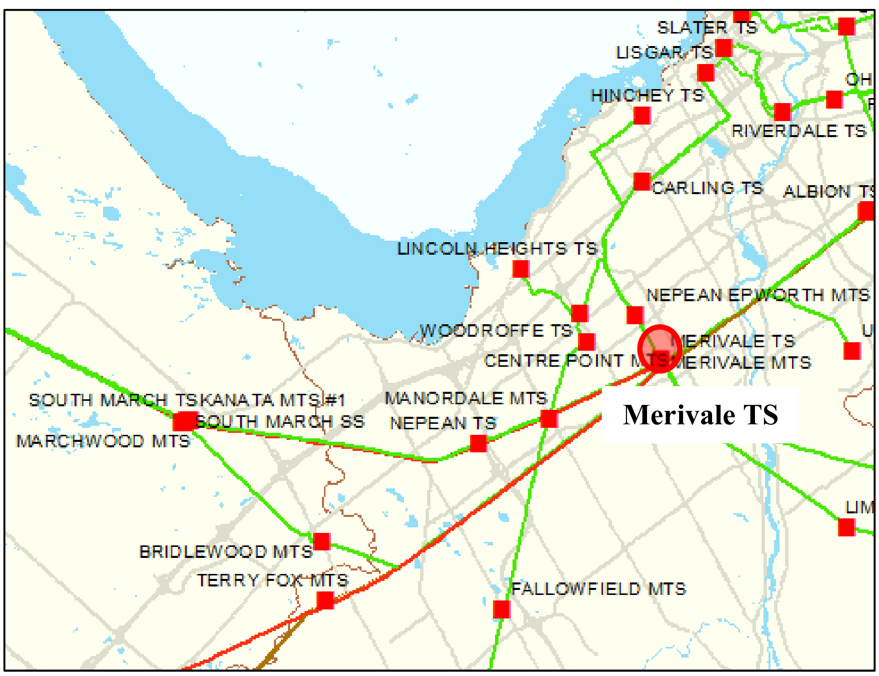

Figure 7-2 Merivale TS

The expected load growth provided by the LDCs and the minimum hydro generation assumption described in Section 6.2 causes the station capacity to be exceeded under contingency conditions by 2019. In addition, it is expected that autotransformers at Merivale TS and Hawthorne TS will reach their continuous loading limits of 250 MVA by 2024 and 2025. The exact timing of the autotransformer needs is dependent on the following factors:

- The South West area load forecast includes a proposed connection of a single large load increase coming into service in 2019.
- The need date is sensitive to generation at Stewartville GS, Barrett Chute GS and Chats Falls GS as its effect is to reduce the flow through the autotransformers.
- A potential solution to the need for additional supply capacity in the South West Area is a new 230 kV supply station which would remove some of the demand growth and existing load from the 115 kV network (see Section 7.2.2 for a complete description of this issue). This work would also help defer the need for additional autotransformer capacity at Merivale TS.

In order to address the Merivale TS autotransformer capacity concerns, additional 230/115 kV transformation capacity or load transfer from the 115 kV to the 230 kV system is required.

The provision of additional transformation capacity requires replacing the Merivale TS T22 autotransformer with a newer higher rated transformer in 2019 and adding a third autotransformer at the station in 2024. Alternatively a third transformer can be added at Merivale TS by 2019. To meet the required 2019 need date a decision on the autotransformer work is required by summer 2016.

Transferring load to the 230kV system requires establishing a new 230/27.6kV transformer station in the South West area to pick up some of the existing load and all of the new load growth. This is described in the following section.

7.2.2 Supply to South West Area – Line and Station Capacity

The South West area is served by Fallowfield MTS, Richmond MTS and Manotick DS connected to the 115kV circuit S7M out of Merivale TS. Load demand in the area is expected to increase by 52 MW in the next 10 years and both the line and station capacity are forecast to be exceeded by 2019.

The line limitation was identified in the OPA's June 2014 letter [5] to Hydro One. A section of the S7M circuit between the main line at STR R14-R15 JCT and Fallowfield Junction (see Figure 7-3 below) had a capacity of 420A. Hydro One review of the line capacity showed that the line rating was limited to respect safety clearances due to an underbuilt distribution feeder at Fallowfield MTS. This issue has been resolved with Hydro Ottawa carrying out the necessary work to lower the distribution feeder and increase the transmission line clearance. The line rating has been increased to 590A and is now adequate to meet forecast load until 2026.

Additional transformation capacity is required in the South West Area and both Fallowfield MTS and Richmond DS require load relief. Hydro Ottawa is planning for a capacity increase at Richmond DS and potentially a new station to relieve Fallowfield MTS in the Barrhaven area.

The IESO has initiated a public engagement process to gather community input for a preferred supply plan for the area including consideration of the potential for incremental CDM and DG resources and/or transmission expansion in the form of a new TS. The IRRP [1] recommended that given the required timeline, it would be beneficial for early transmission planning options to be started in parallel to the engagement process, prior to completing the integrated plan.

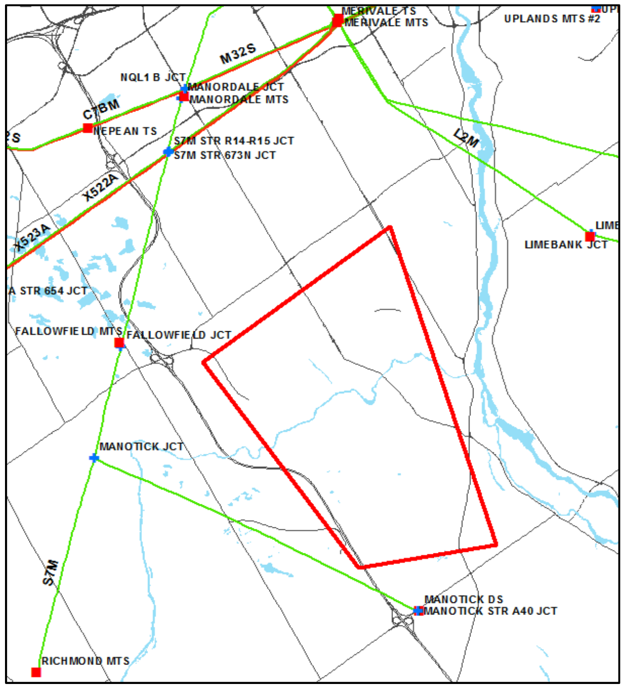

Figure 7-3 South West Area

At a high level, there are two main wire options to supply the South West area:

a) 115kV Option: Build a new 115/27.6kV transformer station and reinforce the existing 115 kV supply
b) 230kV option: Build a new 230/27.6kV transformer station and provide a new 230 kV transmission supply to the area.

The main advantage of the 115 kV option is that it defers the need for new transmission line until 2026. It however has a number of disadvantages: (a) loading will continue to increase on the 115kV system necessitating additional transformation capacity a Merivale TS by 2019 and Hawthorne TS by 2025, (b) all area stations remain on a single line supply until new transmission is built, and (c) the new 115 kV supply will provide less incremental capacity for the future.

The 230 kV option has the advantage of providing relief for the 230/115 kV autotransformers at Merivale TS and Hawthorne TS as well as provide more capacity to serve the area load. It also improves the area reliability by providing a second source of supply. The disadvantage is that transmission reinforcement will be required by 2019 and decision needs to be made as soon as possible.

The RIP has considered two options as examples for providing 230 kV supply to the area. Both examples consider building new double circuit 230 kV lines on existing Right of Way (“ROW”) in accordance with the provincial government policy to maximize ROW use. The two options are described below (also refer to Figure 7-3).

- *S7M Based Option - Rebuild S7M as a double circuit 230 kV line.*

  This option would require rebuilding the existing single circuit115 kV circuit S7M tap to Fallowfield MTS as a new double circuit 230 kV line. The line would extend from the S7M STR R14-R15 JCT (on the main line) to Manotick Jct. Depending on the station location, a part of S7M from Manotick JCT to Manotick DS would also have to be rebuilt for a total line rebuild of up to 15.5 km. One circuit would be operated at 115 kV and continue to supply Fallowfield MTS, Richmond DS and Manotick DS. The other circuit would be tapped off the 230 kV circuit M29C which is adjacent to S7M at STR R14-R15 JCT and will be used to supply the new Hydro Ottawa station. This option may require sections of the existing ROW to be widened to accommodate the 230 kV circuits. Additional real estate rights will have to be obtained. EA and OEB Leave to Construct (Section 92) approvals will also be required.

- *L2M Based Option - Rebuild L2M as a double circuit 230 kV Line*

  This option would require rebuilding the existing 115 kV circuit L2M from Merivale TS to past Limebank MTS as a new double circuit 230 kV line. This section of the line would be constructed using the existing L2M ROW for a distance of 8.5 km. A new 6-8 km long ROW would need to be acquired going west from the L2M ROW to bring the transmission line to the load area, crossing the Rideau River. One circuit on the new line would remain L2M and be operated at 115 kV. The other circuit would connect to circuit M32S at Merivale TS and be operated at 230 kV. The new station will be supplied from the 230 kV circuit.

7.2.3 Recommended Plan and Current Status

The needs for autotransformation capacity and a new station in south west are interrelated. Further analysis is required to determine the impact of the 230 kV supply options for the new south west station on the Merivale TS and Hawthorne TS autotransformers. The planning assessment will consider whether a 115kV supply to the new station in combination with the addition of an autotransformer at Merivale is more cost effective than a 230kV supply.

The IESO is currently carrying out community engagement activities in the Ottawa region. The Working Group will be discussing the supply options for the South West area in conjunction with the autotransformer upgrade work at Merivale TS and expect to recommend a preferred plan for the area by summer 2016.

7.3 115 kV Transmission Circuit A4K Supply Capacity

7.3.1 Description

Circuit A4K is a 115 kV circuit supplying four downtown stations: Overbrook TS, King Edward TS, Cyrville MTS and Moulton MTS. Loading on the A4K this circuit can exceed its rating under peak load conditions for loss of 115 kV circuit A5RK. This need was identified as a near term need in the Ottawa Sub-Region IRRP [1] and included in the OPA's June 2014 letter to Hydro One [5]. In this letter, the preferred plan to relieve circuit A4K is outlined. This plan consists of rebuilding an approximately 2 km long section of single circuit 115 kV circuit A5RK between Overbrook TS to Riverdale Jct. as a double circuit line (see Figure 7-4). One of the circuits would remain A5RK and the other would be tapped to circuit A6R. Overbrook TS will be reconfigured to be supplied from circuits A5RK/A6R instead A4K/A5RK. This reconfiguration would remove Overbrook TS load from 115 kV circuit A4K and eliminate the overloading on A4K for the loss of A5RK.

7.3.2 Current Status

Hydro One has initiated the development work for this line rebuild. The project is currently in the engineering and estimating phase. The project is not expected to require Leave to Construct (Section 92) approval, but will require Environmental Assessment ("EA") approvals.

The project is expected to be in service by spring 2019 and preliminary estimates suggest the cost to be approximately $9 million to $11 million. This work will be part of the Line Connection pool and costs will be recovered from the rate revenue and/or customer capital contribution in accordance with the TSC. As a result, the LDC may be required to make a capital contribution.

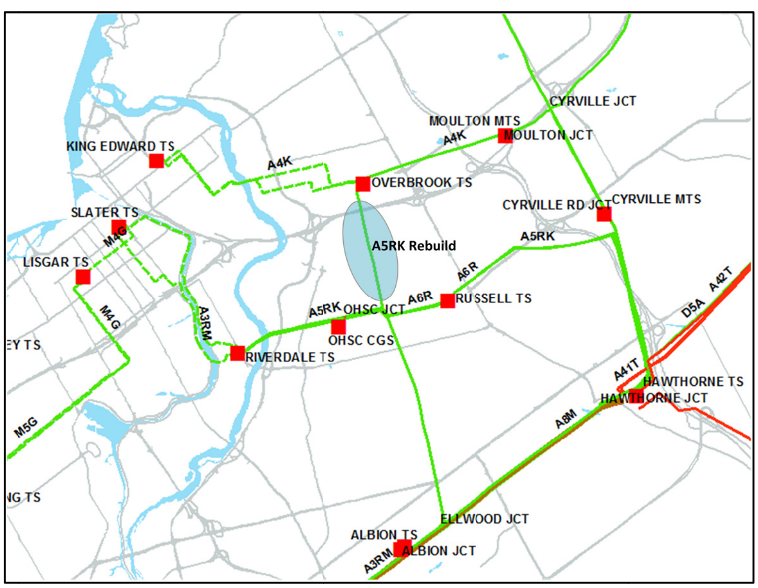

Figure 7-4 Option to Rebuild A5RK as Double-Circuit 115 kV Line

In the interim, Hydro One and Hydro Ottawa have operational mitigating measures to manage the overload on 115 kV circuit A4K if it becomes of concern before Hydro One has completed the line rebuild work. These measures include the transfer of Cyrville MTS to single supply from circuit A2 only by opening the A4K breaker at Cyrville MTS, and the transfer of some load from Moulton MTS to other stations in the area.

7.4 Station Capacity – Ottawa Centre 115 kV Area

7.4.1 Description

The Ottawa Center 115 kV area covers the City of Ottawa downtown district and extends from the Ottawa River in the north to Smyth Road in the south as shown in Figure 7-5 below. It is served by six 115/13.2 kV step-down transformer stations – King Edward TS, Lisgar TS, Overbrook TS, Riverdale TS, Russell TS and Slater TS. Most of the area stations are at or near capacity. Even with the Overbrook upgrade work now underway additional load meeting capability is forecast to be required by 2018 as shown in Table 6.3.

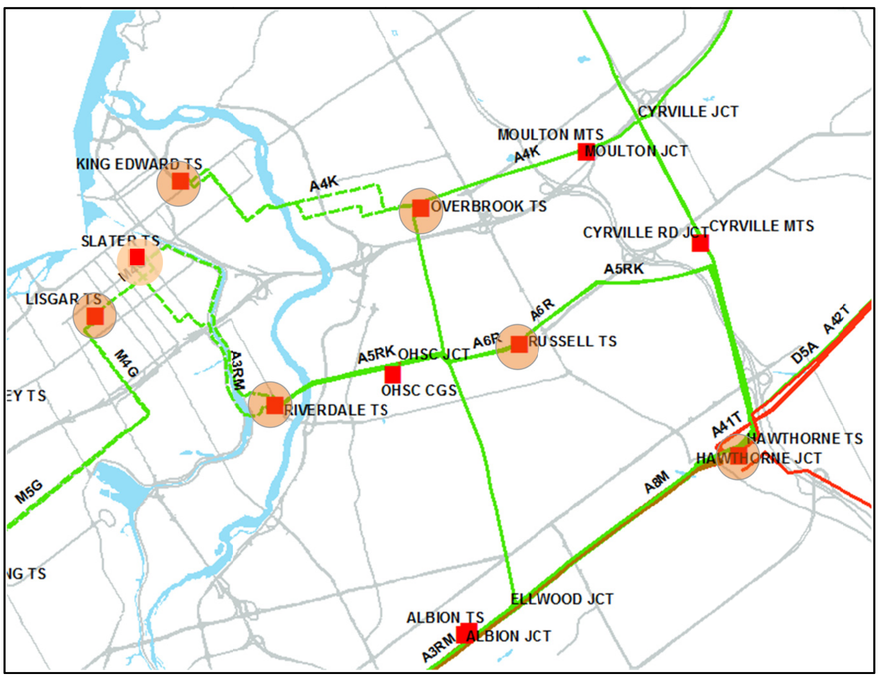

Figure 7-5 Downtown Ottawa Stations

7.4.2 Recommended Plan and Current Status

The existing step-down stations in the area are equipped with older 45/75 MVA transformers which have a LTR of between 70-80 MW. The preferred alternative to provide additional transformation capacity in the area is to replace these units with larger sized 100 MVA units where possible with an LTR of up to 130 MW.

During this regional planning cycle, the Working Group participants agreed to take advantage of transformer replacements necessitated by end-of-life considerations as this was the lowest cost and most practical option to provide additional capacity. The alternative of building a new station to provide capacity was ruled out because of the high cost and the difficulty in acquiring an appropriate site.

Upgrade of the end of life transformers at Overbrook TS is currently underway. In the future, the Working Group will continue to look for opportunities to upgrade based on end-of-life considerations of transformers. Hydro One will keep the Working Group informed of these opportunities. In addition, load transfers are also recommended to utilize available capacity at adjacent stations.

7.4.2.1 Russell TS and Riverdale TS

The loading on these stations will be kept within limits by Hydro Ottawa building feeder ties to transfer excess loads to other area stations. This will keep the loading on the transformers at these stations within their rating. A high level cost estimate of Hydro Ottawa's distribution work is $2 million.

7.4.2.2 Overbrook TS

Hydro One had identified that the step-down transformers at Overbrook TS were approaching end-of-life and consideration was therefore given to upgrading the transformers at the station. Accordingly Overbrook TS transformers are being replaced with larger sized units which will increase the station capacity from 72 MW to 130 MW. The work is underway and planned to be completed in Q2 2018. The incremental cost of upgrading to larger transformers is estimated to be $1.1 million. The cost of upgrading is expected to be recovered from incremental rate revenue in accordance with the TSC. Based on current forecast Hydro Ottawa is not expected to pay any capital contribution for this project.

7.4.2.3 Lisgar TS

Lisgar TS has two 75 MVA transformers. To meet the forecast load requirement additional transformation capacity is required in the Central 115kV area. Hydro Ottawa has therefore asked that the Lisgar TS transformers be replaced with larger 100 MVA units. The cost of the work is estimated to be about $14 million and will be recovered from rate revenue and customer capital contribution in accordance with the TSC. The target in-service date is Q4 2017.

7.4.2.4 King Edward TS

The capacity at King Edward TS is 71 MW. By replacing the limiting transformer T4 and additional low voltage ("LV") components such as circuit breakers and cable, a higher capacity of up to 130 MW can be achieved at King Edward TS.

Considering the Overbrook TS and Lisgar TS upgrades, adequate capacity will be available in the Center area until 2021. After discussion with Hydro Ottawa, the King Edward TS transformer upgrade work is tentatively scheduled for an in-service date of 2021. The project cost is estimated to be about $12M and will be recovered from rate revenue and customer capital contribution in accordance with the TSC.

7.5 Station Capacity - Hawthorne TS 44kV

Hawthorne TS has two 50/83 MVA, 230/44kV transformers with an LTR of 89 MW. Additional 44kV capacity is required at the station. Hydro One identified that the step- down transformers at Hawthorne TS were approaching end-of-life and needed to be replaced. The lowest cost alternative to provide this additional capacity was to take advantage of the transformer replacement work and install larger 75/125 MVA transformers with an LTR of 153 MW. This work is currently underway and planned to be completed by summer 2019.

Additional 44kV feeder positions will be required to utilize this increased capacity. These feeders will be added as required.

The incremental cost of upgrading to larger transformers is estimated to be approximately $1.1 million. Feeder position costs have not been estimated at this time. Incremental transformer costs and the feeder costs will be recovered in accordance with the TSC. Based on the current forecast Hydro Ottawa is not expected to pay any capital contribution for this project.

7.6 Bilberry Creek TS End of Life

7.6.1 Description

Bilberry Creek TS is a 115/27.6 kV step-down transformer in East Ottawa, supplying up to 85 MW of load customers to both Hydro Ottawa and Hydro One Distribution. The station was built in 1964 and a number of its key components have been identified for replacement by Hydro One. This station's refurbishment work is to be complete by 2023. A decision will be required by 2020 on whether to refurbish the station and keep the load on the 115 kV system or to retire the station and move the load over to the 230 kV system by supplying it from the newly built Orleans TS.

A Local Plan [3] carried out by Hydro One shows that the two options are similar in costs. The retirement option however, may be more attractive particularly if 115 kV load growth rate is high in the Ottawa Center area. The retirement option will reduce the loading of the 230 kV/115 kV autotransformers at Hawthorne TS and Merivale TS and make it available for the Ottawa Center 115 kV load. Figure 7-6 shows the area under consideration.

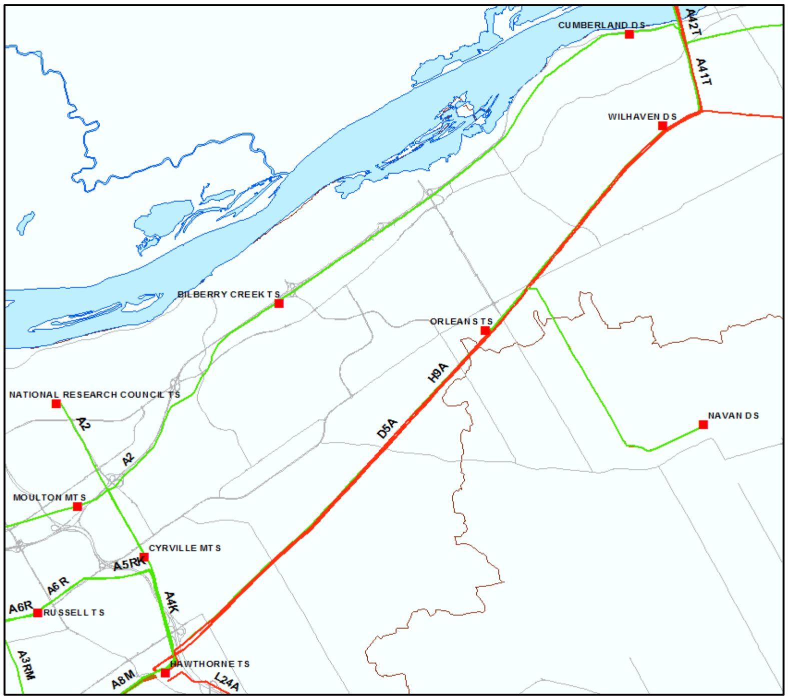

Figure 7-6 Bilberry Creek TS and the East Ottawa Area

7.6.2 Recommended Plan and Current Status

The two alternatives are very similar in cost and each has its own pros and cons. The refurbishment option minimizes work on the distribution system, but leaves the load on the 115kV system and with lower overall capacity to meet long term growth. The retirement option moves Bilberry Creek load to the 230kV system with higher long term load meeting capability but involves relocating distribution feeders from Bilberry Creek TS to Orleans TS.

The Working Group has recommended that a decision on Bilberry Creek refurbishment be deferred to the next regional planning cycle as there is still sufficient time to make an investment decision.

7.7 Almonte TS and Terry Fox TS Reliability

7.7.1 Description

Almonte TS and Terry Fox MTS are supplied from the 319 km long 230kV circuit M29C, see Figure 7-7. Due to the long length of the line the exposure to outages is high. The line has averaged approximately 6-7 interruptions per year over the last 10 years. With Terry Fox MTS coming into service in 2013, concerns were expressed about the number of outages that would be seen by the station. This issue was identified in the Ottawa Sub-Region IRRP [1] and the OPA’s June 2014 letter [5].

7.7.2 Recommended Plan and Current Status

Hydro One had initiated a project in 2012 to install a 230 kV circuit breaker at Almonte TS. This breaker would sectionalize the M29C line into two sections: E29C – 281 km Cherrywood TS to Almonte TS; and E34M – 38 km Almonte TS to Merivale TS. This breaker will help with the number of interruptions at Almonte TS and Terry Fox MTS by eliminating outages due to the Almonte TS x Cherrywood section of the circuit.

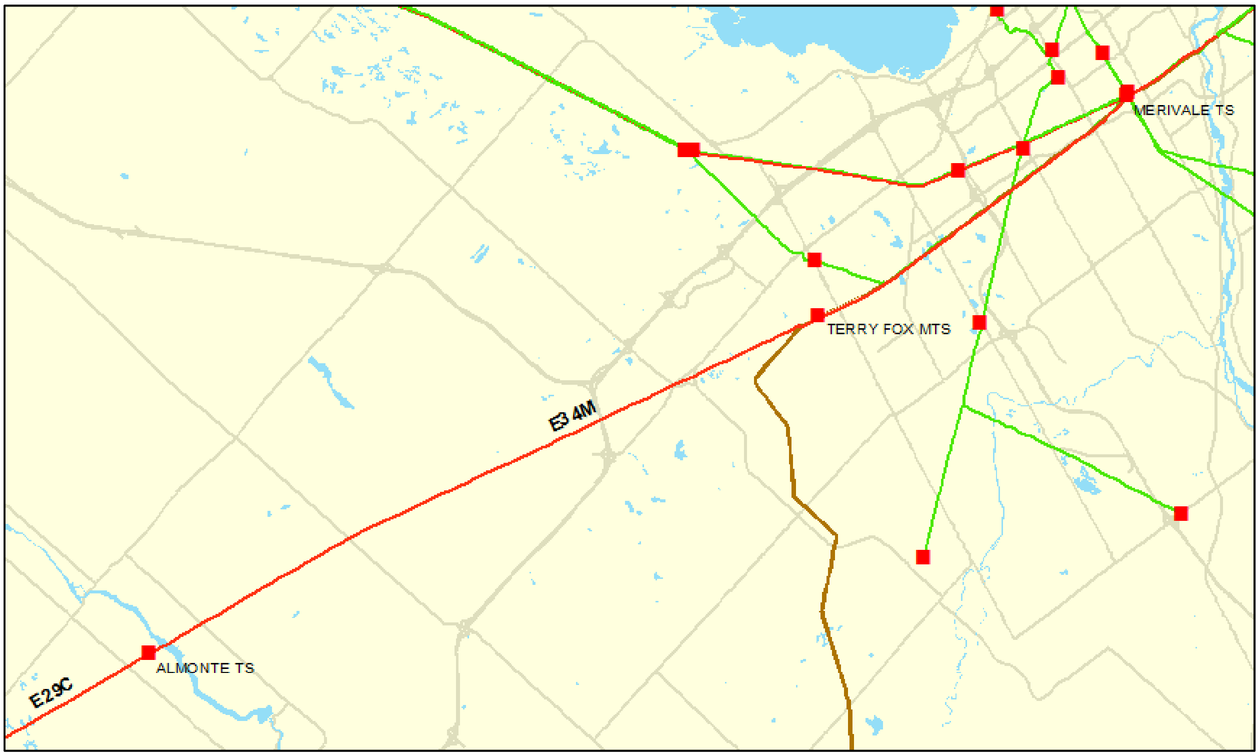

Figure 7-7 Lines E29C and E34M (M29C). In-Line Breaker at Almonte TS.

The total cost of this project is estimated to be $4.7 million and the project is scheduled to be completed by December 2015.

A second supply from Merivale TS to Terry Fox MTS was previously considered as an option to improve reliability. However it was decided to install the in-line breaker at Almonte TS since it was the cost effective and provided reliability improvement to both Almonte TS and Terry Fox MTS.

It should be noted that the Terry Fox TS is operated with the LV bus tie open. This arrangement has the disadvantage that in case of a transformer outage, the load connected to that transformer will be lost momentarily before the bus tie is closed to allow all loads to be supplied from the other side. A second supply to Terry Fox MTS can still be considered to address this issue as the load increases as part of a longer term supply plan. This will continue to be reviewed.

7.8 Orleans TS Reliability

7.8.1 Description

Orleans TS is a new station Hydro One built in East Ottawa to provide additional transformation capability and improve supply reliability for Hydro One Distribution customers connected to the 115 kV circuit H9A.

The Orleans TS is built adjacent to the double circuit H9A/D5A line about 10 km from Hawthorne TS and has one step-down transformer station supplied from 230 kV circuit D5A and the second step-down transformer supplied from the 115 kV circuit H9A. The station is operated with the LV bus tie open so as to avoid any power flow between the 230 kV and 115 kV systems through the station transformers. This arrangement has the disadvantage that in case of a circuit or transformer outage, the load connected to that circuit or transformer will be lost momentarily before the bus tie is closed to allow all loads to be supplied from the other side.

7.8.2 Recommended Plan and Current Status

Orleans TS has greatly improved the reliability of customers previous supplied from Wilhaven DS and Navan DS connected to 115kV circuit H9A. The customers experienced sustained interruptions every time circuit H9A had an outage. With the Orleans TS LV bus tie arrangement customer are exposed to a momentary interruption only as the load is picked up by closing the bus tie. This arrangement was accepted as a cost effective alternative to building 10 km of transmission line between Hawthorne TS and Orleans TS to provide a dual supply to Orleans TS.

Depending on the decision taken for Bilberry Creek TS described in section 7.6, Orleans TS could be converted to a 230 kV station and the LV bus tie closed. This option would be preferred if Bilberry Creek TS is recommended to be retired. If Bilberry Creek TS is refurbished then the plan will see Orleans TS continued operation with two different voltage supplies.

The Working Group recommendation is to monitor the performance of Orleans TS to see if mitigation measures are warranted. The Working Group will further review this issue in the next regional planning cycle as part of the Bilberry TS retirement study. No further action is required at this time.

7.9 Load Restoration for the Loss of B5D/D5A

7.9.1 Description and Current Status

The NA report for the Outer Ottawa Sub-Region [2] identified that the combined loss of circuits D5A and B5D would result in a load loss of up to 174 MW. The stations considered in this analysis are St Isidore TS, Longueil TS, and Ivaco CTS. Orleans TS is also supplied by D5A however; its second supply is H9A and is not considered for the combined loss of D5A/B5D. As indicated in ORTAC, any load lost above 150 MW must be restored within 4 hours and all load be restored within 8 hours.

A LP report [4] carried out by Hydro One shows that historically, the coincidental occurrence of forced sustained outages of B5D and D5A are rare and in all cases one of the circuits was restored in less than 4 hours as per ORTAC. The report concludes that no further action is required at this time.

7.10 Load Loss for S7M Contingency

7.10.1 Description and Current Status

Circuit S7M is the single supply for the following stations: Bridlewood MTS, Fallowfield MTS, Manotick DS, and Richmond DS. The combined load at these four stations is expected to exceed 150 MW by 2022. The ORTAC requires that not more than 150MW of load may be interrupted by configuration. However, given that the 150 MW limit is anticipated in the long term, no action is required at this time.

7.11 Voltage Regulation on 115kV Circuit 79M1

7.11.1 Description and Current Status

The 115 kV circuit 79M1 supplies Rockland DS, Rockland East DS, Clarence DS, Wendover DS, and Hawkesbury MTS. The NA for Outer Ottawa Sub-Region [2] identified that the voltage at Hawkesbury TS will approach operating limits under peak load and contingency conditions by 2023.

As mentioned in the Outer Ottawa Sub-Region NA report [2], Hydro One monitors the status of the network. Given the timing for this need, this will be reassessed during the next regional planning cycle.

7.12 Voltage at Stewartville TS

7.12.1 Description and Current Status

The load on the Stewartville TS is expected to increase significantly as a result of the connection of a large utility load forecasted for 2018. This load may require reactive support to help maintain the voltages within limits during peak load conditions and no generation at Stewartville GS.

A connection impact assessment will be undertaken by Hydro One as part of connecting the utility load. Any requirements to connect the load, including reactive power support, will be outlined in the document.

7.13 Voltage Drop at Terry Fox MTS for E34M open at the Merivale End

7.13.1 Description

Circuit E34M/E29C (new name for circuit M29C following the installation of a breaker at Almonte TS) is a 319 km line between Cherrywood TS in Pickering, and Merivale TS in Ottawa. If the circuit E34M (Almonte-Merivale) is open at the Merivale end, Terry Fox MTS and Almonte TS will be supplied radially by Cherrywood TS. Given the distance between the Greater Ottawa stations and Cherrywood TS, voltages are lower than acceptable limits during normal and peak load periods and only load of up to 25 MW can be supplied with acceptable voltage. The 2012 IESO System Impact Assessment ("SIA") recommended the installation of 20 MVARs of capacitor banks at Terry Fox MTS to meet a peak load of up to 48 MW.

7.13.2 Recommended Plan and Current Status

It is recommended that Hydro Ottawa install 20 MVARs of capacitor banks at Terry Fox MTS. This should be adequate for the near term.

Terry Fox MTS is part of the Ottawa Area under voltage load rejection scheme ("UVLS"). This scheme is designed to shed the station load if the 230 kV supply voltage to the station drops below 204 kV when it is activated. Currently the scheme is only armed when the entire Ottawa Area UVLS is armed. It is proposed to modify the scheme so that it can be selectively armed when loading levels are higher than 48MW and under conditions that may result in a circuit M29C line end open at Merivale TS.

Historically the probability of this line end open occurring is low and it would typically occur while terminal maintenance is done at Merivale. By scheduling maintenance during off peak periods, the impact can be significantly reduced. No mitigation measures are therefore recommended at this time. Hydro One and Hydro Ottawa will be monitoring the system performance and the matter will be reconsidered in the next planning cycle based on operating experience.

7.14 Low Power Factor at Almonte TS

7.14.1 Description and Current Status

The IESO's SIA for Almonte T3 replacement noted a low power factor at Almonte TS. This potential issue was also reported in the Outer Ottawa Sub-Region NA report [2].

Hydro One has reviewed the power factor at Almonte TS. The station power factor varies from 0.89 to 0.95 at the LV bus which translates into approximately 0.86 to 0.92 on the HV bus. Part of the reason for the lower power factor is that the station has 29 MW of DG which generally operates at unity power factor. The generation reduces the net power in MW seen at the metering point. This reduction in power results in a lower power factor as seen from the HV bus since the generation does not offset the reactive power demand of the station. No action is required as the load power factor without DG is within the acceptable limits.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GREATER OTTAWA REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses near term and mid-term regional needs identified in the earlier phases of the Regional Planning process and during the RIP phase. Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the near term needs are summarized in the Table 8-1 below.

Investments to address the mid-term needs, for cases where there is time to make a decision, will be reviewed and finalized in the next regional planning cycle. These needs are summarized in Table 8-2.

No long term needs were identified at this time. As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years.. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Table 8-1 Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

No.	Project	Next Steps	Lead Responsibility	I/S Date	Cost
1	Almonte TS: addition of breaker to sectionalize line M29C	Construction in the final stages	Hydro One	Dec. 2015	$4.7M
2	Russell TS and Riverdale TS: construction of feeder ties to allow extra load transfers	LDC will lead this work	Hydro Ottawa	2017-2020	$2.0M
3	Lisgar TS: replacement of transformers T1 and T2	Transmitter to carry out this work	Hydro One	Dec. 2017	$13.9M
4	Hawthorne TS: replacement of autotransformers T5 and T6	Transmitter to carry out this work	Hydro One	May 2018	$15.7M
5	Overbrook TS: replacement of transformers T3 and T4	Transmitter to carry out this work	Hydro One	June 2018	$1.1M(1)
6	A6R: additional tap to offload A4K	Transmitter to carry out this work	Hydro One	June 2019	$9-11M
7	Hawthorne TS: replacement of transformers T7 and T8 and add one 44kV feeder position	Transmitter to carry out this work	Hydro One	Oct. 2019	$1.1M(2)
8	New South West Station And Merivale 230/115kV Transformation Capacity	IESO and Hydro Ottawa leading consultation	IESO/Hydro Ottawa	2020	--- (3)
9	King Edward TS: Replace Transformer T4	Transmitter to carry out this work	Hydro One	June 2021	$12M

(1) Incremental cost for larger transformer only.
(2) Incremental cost for larger transformer only. Feeder costs have not been estimated at this time.
(3) The Working Group expects to make a final recommendation on this plan by early 2016.

Table 8-2 List of Mid-Term Needs to be Reviewed in Next Regional Planning Cycle

No.	Need	Timing
1	Bilberry Creek TS - Refurbishment	2023
2	Orleans TS - Reliability	2023[(1)]
3	79M1 Circuit – Voltage regulation	2023

(1) Performance will be monitored to see if mitigation measures are warranted. Need will be reviewed along with Bilberry Creek TS refurbishment.

APPENDIX E: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

GTA East

REGIONAL INFRASTRUCTURE PLAN

January 9th, 2017

hydro one

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
Oshawa PUC Networks Inc.
Veridian Connections Inc.
Whitby Hydro Electric Corporation

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE NETWORKS INC. ("HYDRO ONE") AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS OF THE GTA EAST REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Oshawa PUC Networks Inc.
- Veridian Connections Inc.
- Whitby Hydro Electric Corporation
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the OEB's mandated regional planning process for the GTA East Region which consists of the Pickering-Ajax-Whitby Sub-Region and the Oshawa-Clarington Sub-Region. It follows the completion of the GTA East Region's Needs Assessment ("NA") in August 2014, the Oshawa-Clarington Sub-Region's Local Plan ("LP") in May 2015, and the Pickering-Ajax-Whitby Sub-Region's Integrated Regional Resource Plan ("IRRP") in June 2016.

This RIP provides a consolidated summary of needs and recommended plans for the entire GTA East Region that includes the Pickering-Ajax-Whitby Sub-Region and Oshawa-Clarington Sub-Region. The major transmission and distribution infrastructure investments planned for the GTA East Region over the near and mid-term, as identified in the regional planning process are given below.

No.	Project	I/S Date	Cost
1	Enfield TS; new 230/44kV station	2019	$34M[1]
2	Seaton MTS; new 230/27.6/27.6kV station	2019	$43M-$48M[2]

As per the Regional Planning process, the Regional Plan will be reviewed and/or updated at least once every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

[1] Considers 6x44kV feeder breaker positions initially without capacitor banks
[2] Class Environmental Assessment (EA) not complete at time of RIP. Range of costs includes all sites under consideration – includes transmission line rebuild costs and all station equipment less capacitor banks for 12x27.6kV feeders and a spare transformer.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA EAST REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the study with input and consultation with Hydro One Distribution, Oshawa PUC Networks Inc. ("OPUCN"), Veridian Connections Inc. ("Veridian"), Whitby Hydro Electric Corporation ("Whitby Hydro") and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa, and Clarington. Electrical supply to the Region is provided through 500/230kV autotransformers at Cherrywood Transformer Station ("TS") and five[3] 230kV transmission lines that supply the four local area step-down transformer stations. The boundaries of the Region are shown in Figure 1-1 below.

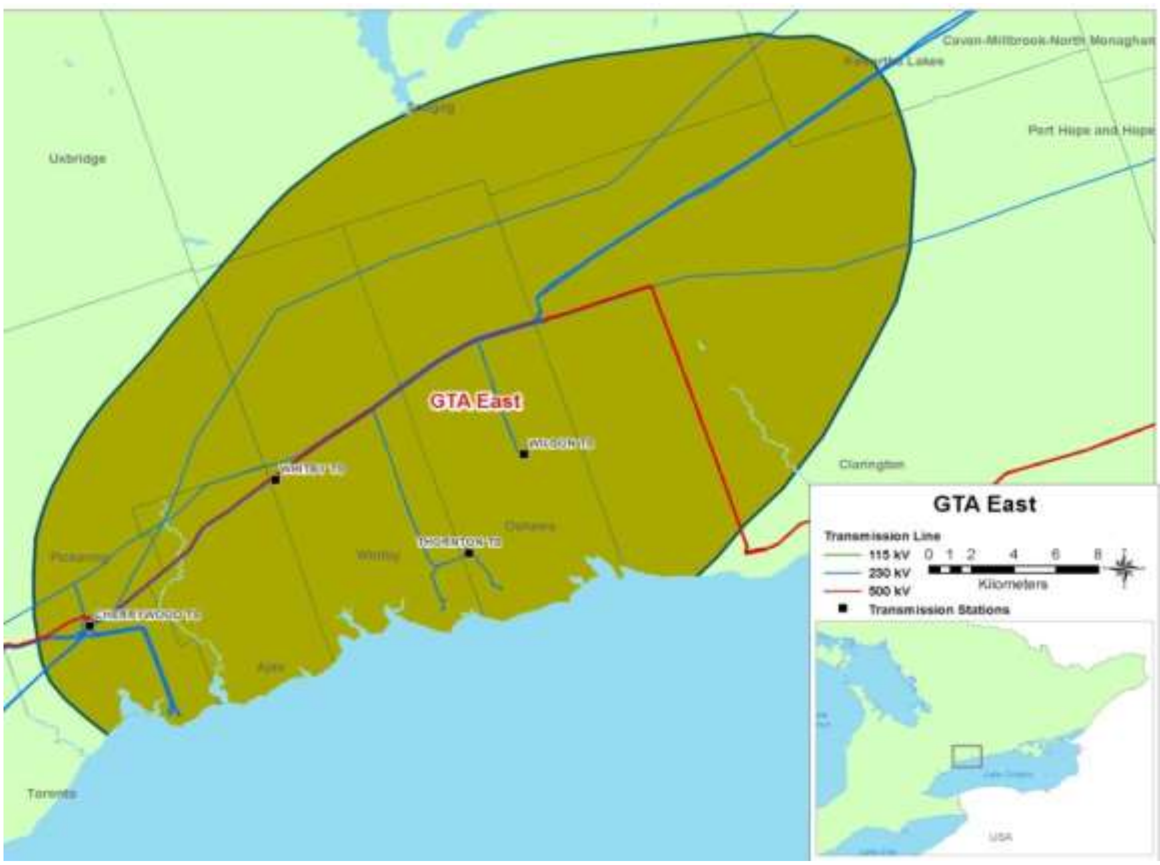

Figure 1-1 GTA East Region

[3] Including 230kV circuit C28C (T28C with Clarington TS) which extends 2km north from Cherrywood TS to Duffin Jct. and then extends 26km east to be terminated at Clarington TS in 2018

1.1 Scope and Objectives

This RIP report examines the needs in the GTA East Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2016-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2016-2025 period and a wires plan to address them;
- Consideration of long-term needs identified in the Pickering-Ajax-Whitby Sub-Region IRRP

As per the Regional Planning process, the Regional Plan for the region will be reviewed and/or updated at least every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the regional characteristics
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the regional needs
- Section 7 describes the needs and provides the alternatives and preferred solutions
- Section 8 provides the conclusion and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115kV and 230kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[4] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, and needs are local in nature, an assessment is undertaken for any necessary investments directly by the LDCs (or customer) and the transmitter through a Local Plan ("LP"). These needs are local in nature and can be best addressed by a straight forward wires solution. The Working Group recommends a LP undertaking when needs are a) local in nature b) limited investments of wires (transmission or distribution) solutions c) does not require upstream transmission investments d) does not require plan level stakeholder engagement and e) other approvals such as Leave to Construct (S92) application or Environmental Approval.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. If there are needs that do not required regional coordination, Working Group can recommend them to be undertaken as part of the LP approach discussed above. Else, the approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

[4] Also referred to as Needs Screening.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee ("LAC") in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

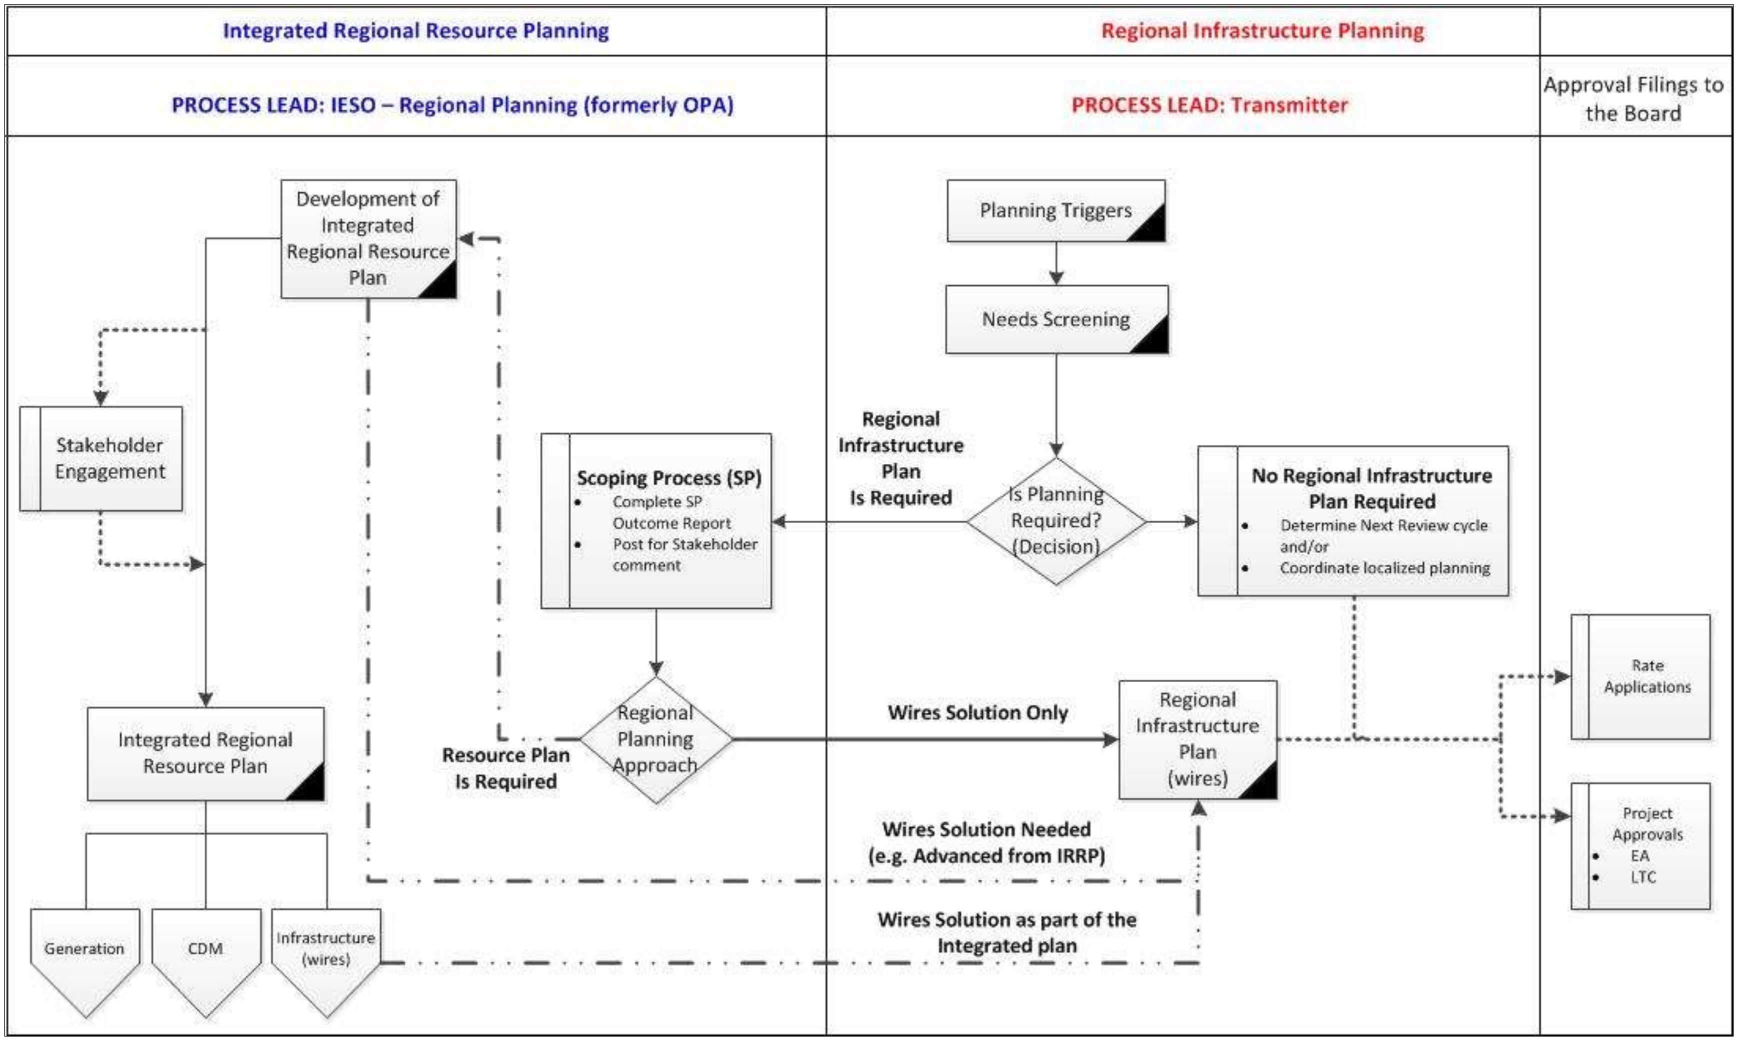

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects the following information and reviews it with the Working Group to reconfirm or update the information as required.

    - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation ("DG") or CDM programs;
    - Existing area network and capabilities including any bulk system power flow assumptions;
    - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

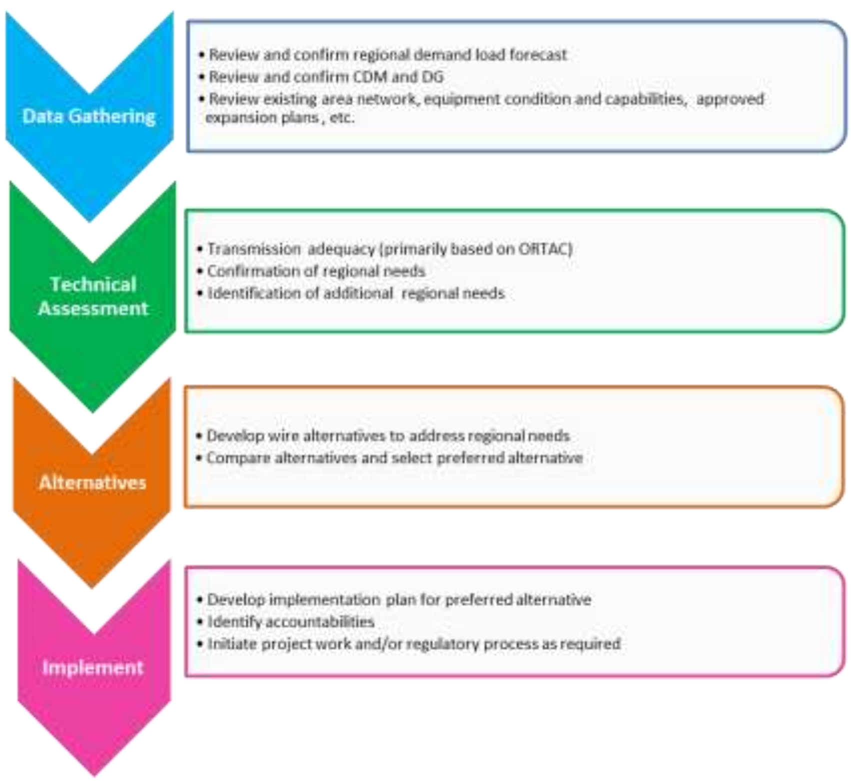

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GTA EAST REGION IS COMPRISED OF THE PICKERING-AJAX-WHITBY SUB-REGION AND THE OSHAWA-CLARINGTON SUB-REGION. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FOUR 230KV STEP-DOWN TRANSFORMER STATIONS. THE 2015 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 938.5 MW INCLUDING DIRECT TRANSMISSION-CONNECTED CUSTOMERS.

Bulk electrical supply to the GTA East Region is currently provided through Cherrywood TS, a major 500/230kV autotransformer station in the City of Pickering, and five 230kV circuits emanating east from Cherrywood TS that supply four local area step-down transformer stations and four other direct transmission connected load customers. Major generation in the area includes the Pickering Nuclear Generating Station (“NGS”) which consists of six generating units with a combined output of approximately 3000 MW and is connected to the 230kV system at Cherrywood TS.

The August 2014 GTA East Region NA report, prepared by Hydro One, considered the GTA East Region as a whole. Subsequently, the GTA East Region was divided into two sub-regions, Pickering-Ajax-Whitby Sub-Region and Oshawa-Clarington Sub-Region. The IRRP report focused on the needs in the Pickering-Ajax-Whitby Sub-Region. The May 2015 Oshawa-Clarington Sub-Region LP report focused solely on the Oshawa-Clarington Sub-Region. A map of the GTA East Region is shown in Figure 3-1 and a single line diagram of the transmission system is shown in Figure 3-2.

3.1 Pickering-Ajax-Whitby Sub-Region

The Pickering-Ajax-Whitby Sub-Region comprises primarily the City of Pickering, Town of Ajax, part of the Town of Whitby, and part of the Townships of Uxbridge and Scugog. It is supplied by Cherrywood TS, a 500/230kV autotransformer station, two 230kV transformer stations, namely Cherrywood TS DESN and Whitby TS (2 DESNs), that step down the voltage to 44kV and 27.6kV. The LDCs supplied in the Sub-Region are Hydro One Distribution, Veridian, and Whitby Hydro.

3.2 Oshawa-Clarington Sub-Region

The Oshawa-Clarington Sub-Region comprises primarily the City of Oshawa, part of the Municipality of Clarington, part of Whitby, and part of the Township of Scugog. It is supplied by Cherrywood TS, a 500/230kV autotransformer station, two 230kV transformer stations, namely Wilson TS (2 DESNs) and Thornton TS, that step down the voltage to 44kV, and four other direct transmission connected load customers. Local generation in the area consists of the 60 MW Whitby Customer Generating Station (“CGS”), a gas-fired cogeneration facility that connects to 230kV circuit H26C. Thornton TS also supplies some load within the Pickering-Ajax-Whitby Sub-Region. The LDCs supplied in the Sub-Region are Whitby Hydro, Hydro One Distribution, and OPUCN.

A new 500/230kV autotransformer station in the GTA East Region within the township of Clarington (called Clarington TS) is also being developed and is expected to be in-service in 2018. The new Clarington TS will provide additional load meeting capability in the Region and will eliminate the overloading of Cherrywood autotransformers that may result after the retirement of the Pickering NGS. The new autotransformer station will consist of two 750MVA, 500/230kV autotransformers and a 230kV switchyard. The autotransformers will be supplied from two 500kV circuits that pass next to the proposed site. The 230kV circuits supplying the east GTA will be terminated at Clarington TS. Clarington TS will become the principal supply source for the GTA East Region load.

A single line diagram of the GTA East Region transmission system including the connection of Clarington TS is shown in Figure 3-2.

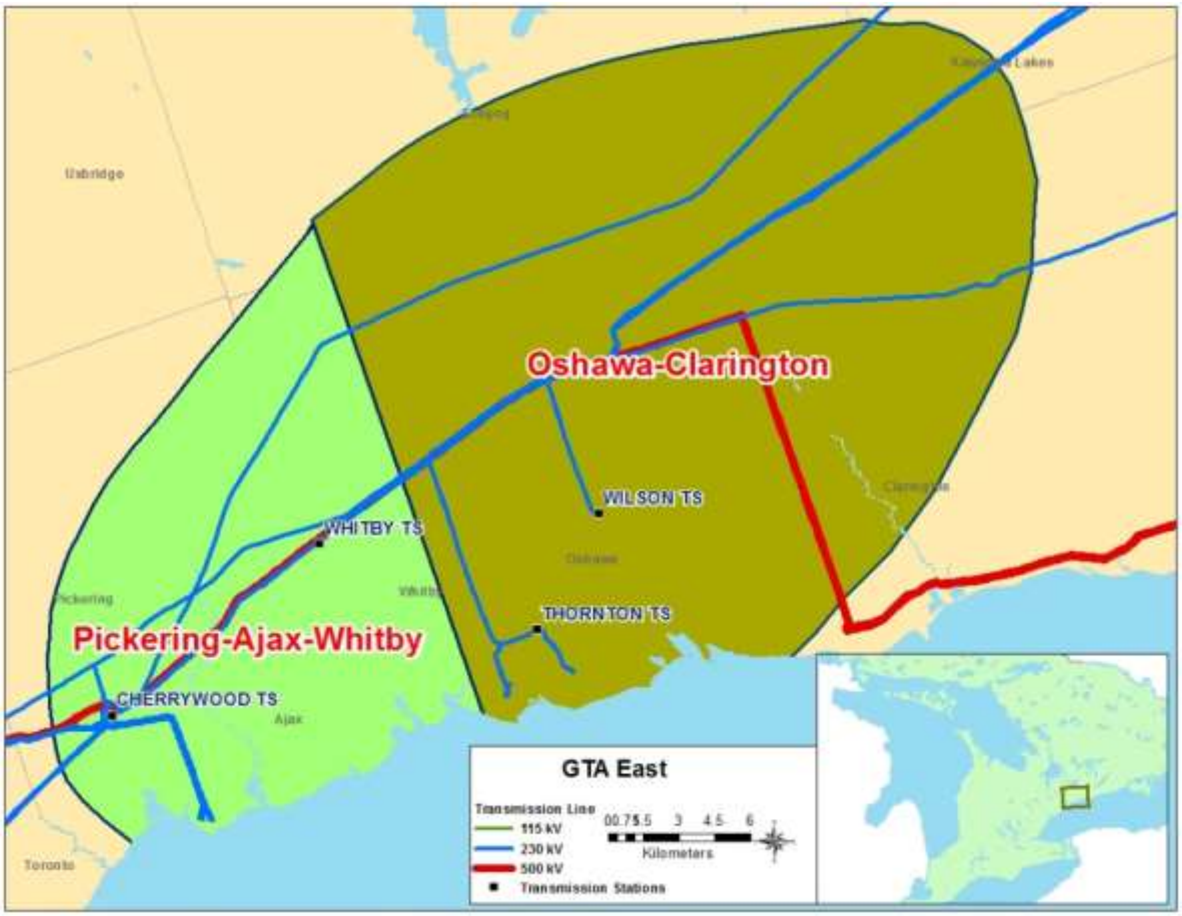

Figure 3-1 GTA East Region – Supply Areas

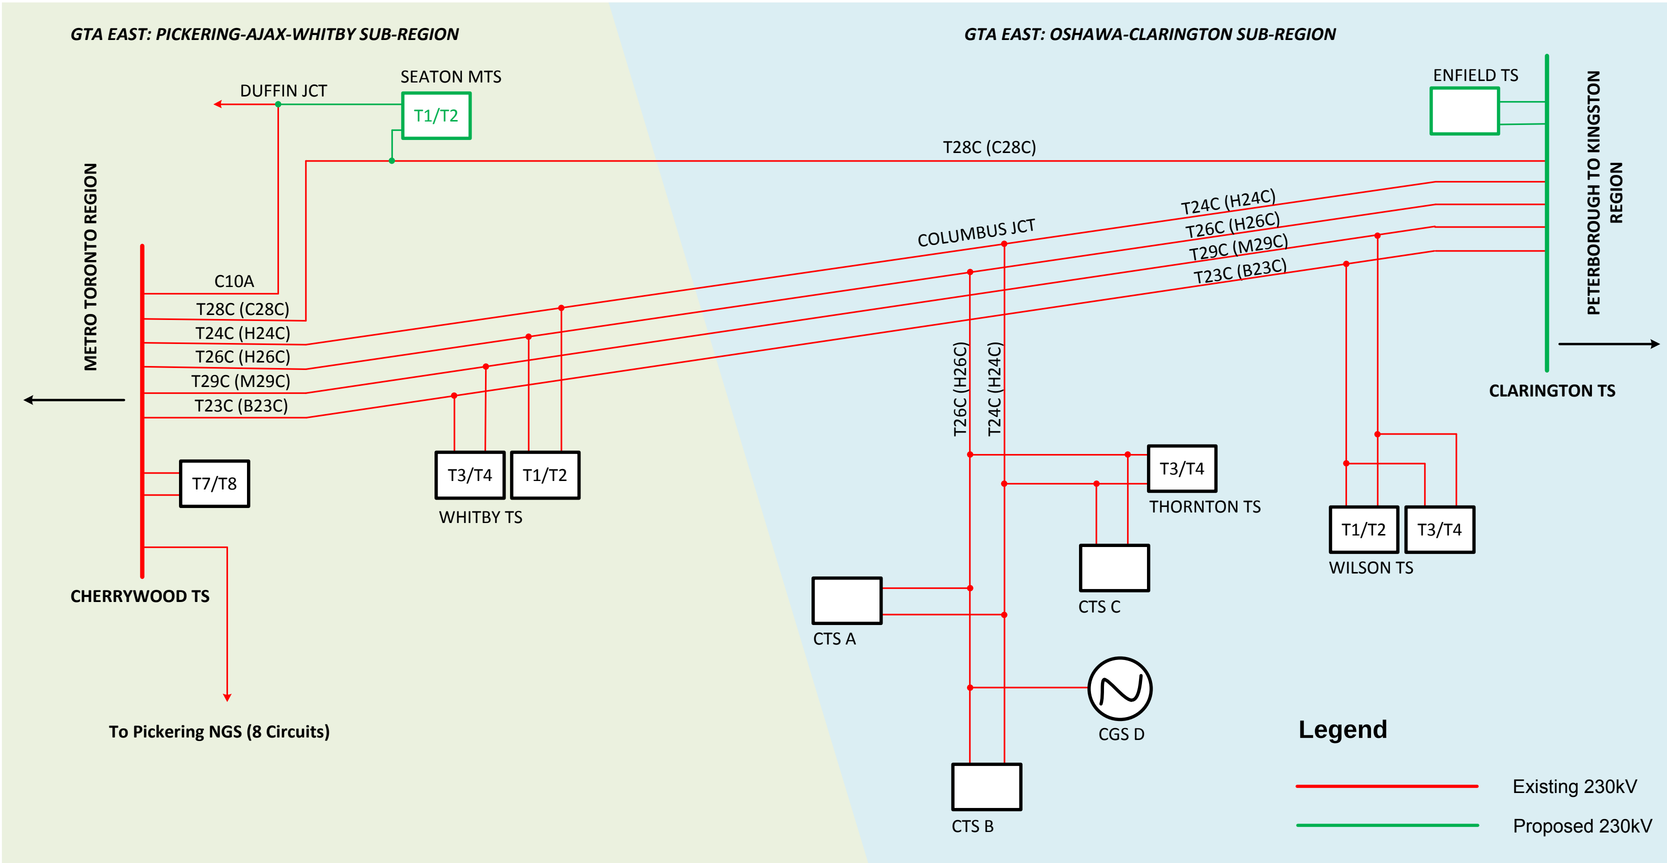

Figure 3-2 GTA East Region Single Line Diagram

Note: Current circuit designations (before Clarington TS is in-service) are provided in brackets

4. TRANSMISSION FACILITIES COMPLETED OR CURRENTLY UNDERWAY OVER LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GTA EAST REGION.

A brief listing of the developed projects along with their in-service dates over the last 10 years is given below:

- Whitby TS T1/T2 (2009) – built new step-down transformer station supplied from 230kV circuits H24C and H26C in municipality of Whitby to increase transformation capacity for Whitby Hydro and Veridian requirements.

- Installed LV neutral grounding reactors at Wilson TS T1/T2 DESN1 (2015) – to reduce line-to-ground short circuit fault levels to facilitate DG connections.

- Thornton TS T3/T4 transformer replacements and install LV neutral grounding reactors (2016) – to replace end-of-life transformers and reduce line-to-ground short circuit fault levels to facilitate DG connections.

The following development projects are currently underway:

- Clarington TS (2018) – a 500/230kV autotransformer station at the Oshawa Area Jct. to increase transmission supply capacity to the GTA East Region, eliminate the overloading of Cherrywood TS autotransformers that may result after the retirement of Pickering NGS, and improve supply reliability to the Region. The thermal limits of the 230kV circuits supplying the Region will be upgraded and will be terminated at Clarington TS.

- Seaton MTS (2019) – a 230/27.6/27.6kV municipal transformer station to increase supply capacity in the Pickering-Ajax-Whitby Sub-Region and provide relief to Whitby TS 27.6kV following the development of new community of Seaton. The station will be serviced by two parallel 230kV circuits, C10A and C28C, emanating from Cherrywood TS. C10A will be extended eastward from Duffin Jct. to the site of the station.

- Enfield TS (2019) – a 230/44kV DESN to increase supply capacity in the Oshawa-Clarington Sub-Region and provide relief to Wilson TS. This station will be located at the Oshawa Area Jct. and will be directly connected to Clarington TS 230kV bus.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA East Region is expected to increase at an annual rate of approximately 2% between 2016 and 2025. The growth rate varies across the Region but an overall coincident growth in the Region is illustrated in Figure 5-1. The gross and net non-coincident and coincident load forecast, adjusted for extreme weather, CDM, and DG, for each station in the region are provided in Appendix C and D.

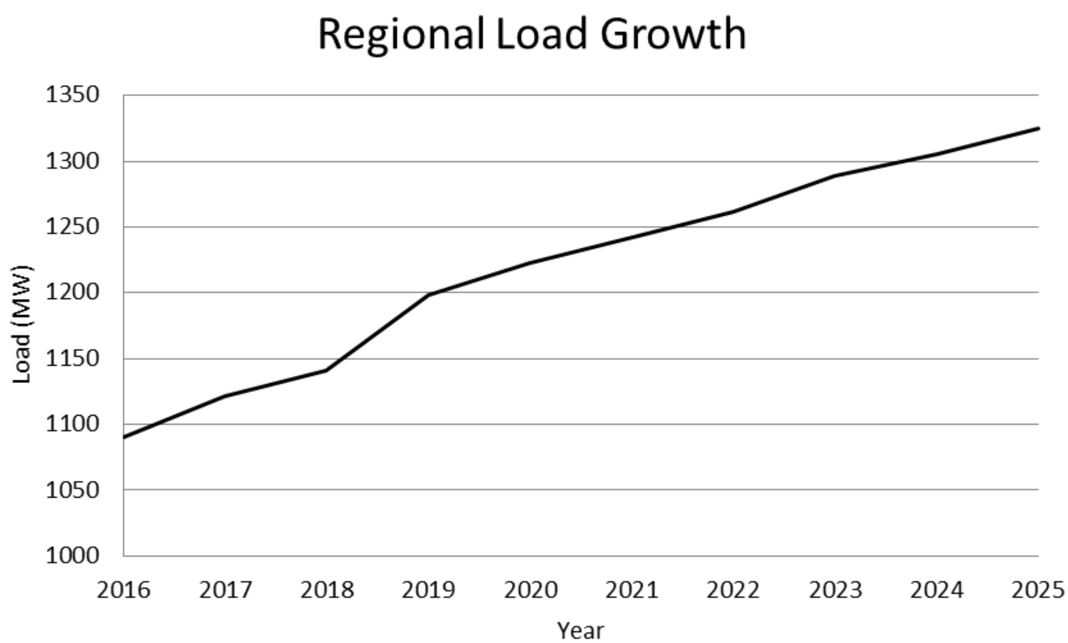

Figure 5-1 GTA East Region Coincident Net Load Forecast

Prior to the RIP's kick-off, the Working Group were asked to confirm load forecast for all stations in the Region provided for previous assessments. The RIP's load forecast for Pickering-Ajax-Whitby Sub-Region did not have a significant revision compared to the IRRP's load forecast. However, the revised forecasted non-coincident stations' peaks for Wilson TS and Thornton TS in the Oshawa-Clarington Sub-Region had a significant increase; therefore, the needs identified in previous assessments were reconfirmed.

5.2 Other Study Assumptions

Further assumptions are as follows:

- The study period for the RIP assessment is 2016 – 2025.
- Pickering NGS is assumed to be out-of-service by 2024.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on extreme summer peak loads.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this region is determined by the summer 10-Day Limited Time Rating ("LTR").

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND STEP DOWN TRANSFORMATION STATION FACILITIES SUPPLYING THE GTA EAST REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM PERIOD.

Within the current regional planning cycle, three regional assessments have been conducted for the GTA East Region. The findings of these studies are input to the RIP:

1. IESO's Pickering-Ajax-Whitby Sub-Region Integrated Regional Resource Plan – June 30, 2016[1]
2. Hydro One's Oshawa-Clarington Sub-Region Local Planning Report – May 15, 2015[2]
3. Hydro One's GTA East Region Needs Assessment Report – August 11, 2014[3]

The IRRP, NA, and LP studies identified a number of regional needs based on the forecast load demand over the near to mid-term. A detailed description and status of plans to meet these needs is given in Section 7.

Based on the regional growth rate referred to in Section 5, this RIP reviewed the loading on transmission lines and stations in the GTA East Region assuming Clarington TS will be in-service by 2018, Seaton MTS and Enfield TS by 2019, and Pickering NGS out-of-service between 2018 and 2024.

Sections 6.1 – 6.3 present the results of this review and Table 6-1 lists the Region's near to mid-term needs identified in both the IRRP and RIP phases.

Table 6-1 Near and Mid-Term Needs in the GTA East Region

Type	Section	Needs	Timing
Step-down Transformation Capacity	7.1	Additional transformation capacity for Whitby TS T1/T2 27.6kV in Pickering-Ajax-Whitby Sub-Region	2019
	7.2	Additional transformation capacity for Wilson TS T1/T2 & T3/T4 in Oshawa-Clarington Sub-Region	Immediately
Load Restoration	7.3	Load Restoration for loss of B23C/M29C or H24C/H26C	No action required at this time
Short Circuit Constraint	7.4	Short Circuit Constraint at Cherrywood TS T7/T8	Pending outcome

6.1 500kV and 230kV Transmission Facilities

The GTA East Region is comprised of five 230kV circuits, B23C/M29C, H24C/H26C, and C28C, supplying both the Pickering-Ajax-Whitby Sub-Region and the Oshawa-Clarington Sub-Region. Refer to Figure 3-2 for existing and proposed facilities to be operational in the Region in near future.

Bulk system planning is conducted by the IESO and is informed by government policy such as the long term energy plan ("LTEP"). The next LTEP is expected to be issued in 2017. Any outcomes from this level of planning that impact regional planning are expected to be integrated into the respective regions as necessary.

6.2 Pickering-Ajax-Whitby Sub-Region's Step-Down Transformer Station Facilities

There are two step-down transformer stations in the Pickering-Ajax-Whitby Sub-Region as follows:

Table 6-2 Step-Down Transformer Stations in Pickering-Ajax-Whitby Sub-Region

Station	DESN	Voltage Transformation
Cherrywood TS	T7/T8	230/44kV
Whitby TS	T1/T2	230/44/27.6kV
	T3/T4	230/44kV

Based on the LTR of these load stations, additional 27.6kV capacity is required at Whitby TS T1/T2 in 2019 which will be addressed by the proposed Seaton MTS (see details in Section 7.1). Cherrywood TS T7/T8 may be slightly overloaded initially, however, due to CDM and commissioning of Seaton MTS, the capacity need is expected to be eliminated by 2019. Forecast loads at Whitby TS T1/T2 44kV windings, and Whitby TS T3/T4 44kV windings are adequate over the study period.

The stations' actual non-coincident peaks, the associated station capacity, and need dates are summarized in Table 6-3.

Table 6-3 Transformation Capacities in the Pickering-Ajax-Whitby Sub-Region

Station	LTR (MW)	2015 Summer Peak (MW)	Relief Required By
Cherrywood TS T7/T8 44kV	175	156	-
Whitby TS T1/T2 27.6kV	90	41	2019
Whitby TS T1/T2 44kV	90	56	-
Whitby TS T3/T4 44kV	187	161	-

6.3 Oshawa-Clarington Sub-Region's Step-Down Transformer Station Facilities

There are two step-down transformer stations and four direct-connected customers in the Oshawa-Clarington Sub-Region as follows:

Table 6-4 Step-Down Transformer Stations in Oshawa-Clarington Sub-Region

Station	DESN	Voltage Transformation
Wilson TS	T1/T2	230/44kV
	T3/T4	230/44kV
Thornton TS	T3/T4	230/44kV
Industrial Customer TS x4	-	-

Based on the LTR of these load stations, additional 44kV capacity is immediately required to provide relief to Wilson TS. Under certain conditions, overloading at Wilson TS T3/T4 was significant enough to plan for emergency rotating load shedding, if and when required. Plan to address this need is discussed further in Section 7.2. Thornton TS is adequate to meet the net demand over the study period.

The stations' actual non-coincident peaks, the associated station capacity, and need dates are summarized in Table 6-5.

Table 6-5 Transformation Capacities in the Oshawa-Clarington Sub-Region

Station	LTR (MW)	2015 Summer Peak (MW)	Relief Required By
Wilson TS T1/T2 44kV	161	167	Immediately
Wilson TS T3/T4 44kV	133	146	Immediately
Thornton TS T3/T4 44kV	159	126	-

The non-coincident and coincident load forecast for all stations in the Region is given in Appendix C and Appendix D, respectively.

7. REGIONAL PLANS

This section discusses the needs, wires alternatives and the current preferred wires solution for addressing the electrical supply needs in the GTA East Region. These needs are listed in Table 6-1 and include needs previously identified in the IRRP for the Pickering-Ajax-Whitby Sub-Region and the NA and LP for the Oshawa-Clarington Sub-Region. Needs for which work is already underway are also included.

The near-term needs include needs that arise over the first five years of the study period (2016 to 2020) and the mid-term needs cover the second half of the study period (2021-2025).

7.1 Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-Region

Description

The Pickering-Ajax-Whitby Sub-Region is supplied by Cherrywood TS at 44kV level and Whitby TS at 27.6kV and 44kV levels. Over the next 10 years, the load in this Sub-Region is forecasted to increase at approximately 2.1% annually.

Based on the DG and CDM forecasts in the Sub-Region, adequate 44kV transformation capacity is available at Cherrywood TS T7/T8 and Whitby TS to maintain reliable supply to meet the demand over the study period.

With the proceeding of a new residential and mixed use commercial area in the Sub-Region, called Seaton, significant increase in load demand is expected at 27.6kV level resulting in a shortage transformation capacity by 2019. The gross demand in the new development of Seaton is expected to be 88MW at the end of the study period (2025) and will continue to grow over long term period. The growth resulting from Seaton will have a significant impact on the 27.6kV transformation capacity in the Sub-Region.

Recommended Plan and Current Status

During the regional planning process, the Working Group considered multiple alternatives to address the transformation capacity in the Sub-Region. Preference was given to already existing facilities to ensure system's maximum capacity had been considered in line with the future demand. Other alternatives included CDM, local generation, and transmission & distribution facilities.

After considering estimated DG and CDM targets over the study period, the stations' capacities in the Sub-Region can be relieved to a certain extent. However, existing facilities alone will not be adequate to meet the future demand resulting from the new Seaton community load planned to be supplied at 27.6kV level.

As a result, an investment in wires infrastructure development in the Sub-Region is mandatory to connect and supply the development of Seaton via transmission/distribution facilities. Following the completion of the IRRP, the Working Group recommended Seaton MTS as the best solution to meet the transformation capacity need in the Sub-Region. Veridian Connections Inc. and Hydro One Networks Inc. have jointly submitted an EA application for the proposed station site and related 230kV transmission line work. Consistent with the regional planning studies, Veridian Connections Inc. is developing a plan for a new transformation station called Seaton MTS in northern Pickering. As confirmed by Veridian, the in-service timeline of this transformation station has been deferred to 2019 due to revised 2018 load forecast.

Class Environmental Assessment (EA) is in progress for the three potential construction sites for Seaton MTS illustrated in Figure 7-1.

Figure 7-1 Seaton MTS: Proposed Construction Sites

The project will have the following connection arrangement:

- From Duffin Jct, extend the circuit C10A east to proposed location under EA process
- Connect 2x75/125MVA, 230/27.6/27.6kV transformers to 230kV circuits; C10A and T28C[5]
- Supply 12x27.6kV feeders with a normally open tie-breaker configuration

The total cost of this project is estimated to be $43M – $48M. This estimate includes the cost of transmission as well as distribution investments which include the station's construction, its connection

[5] T28C circuit nomenclature to replace C28C following Clarington TS (2018)

arrangements as defined above, feeder egress to the distribution risers outside of the station, and a spare transformer.

7.2 Increase Transformation capacity in Oshawa-Clarington Sub-Region

Description

The load forecast reflects an annual growth of 1.85% in Oshawa and Clarington area throughout the study period. Based on the 2015 historical demand and station's net demand forecast, Wilson TS T1/T2 and T3/T4 have already exceeded their respective normal supply capacities and will continue to do so over the study period. Overloading at Wilson TS T3/T4 has been significant enough that plans were put in place for emergency rotating load shedding, if and when required. Thornton TS may briefly exceed its transformation capacity in 2018 and 2019 but is adequate over the study period as well as long term period due to CDM contributions and distribution load transfer capability.

Therefore, based on the current load forecasts, additional transformation capacity relief is required for Wilson TS to accommodate the load growth and improve reliability in this sub-region.

Recommended Plan and Current Status

To accommodate the load growth of Hydro One Distribution's and OPUCN's feeders at Wilson TS, a new transformer station, Enfield TS, is recommended to relief the transformation capacity. The proposed transformer options to be evaluated for the DESN are as follows:

1. 2x75/125MVA, 230/44kV transformers with 6x44kV feeder breaker positions, with space for future 2x44kV feeder positions and capacitor banks (Preliminary Cost Estimate: $23 million)
2. 2x75/125MVA, 230/44kV transformers with 8x44kV feeder breaker positions (Preliminary Cost Estimate: $27 million)

The Working Group recommends option 1 to address the transformation capacity need in the Sub-Region. Six feeders will be adequate to supply demand over the study period. Also, option 2 is not considered the best economic solution since option 1 will reserve extra space for 2x44kV feeder positions and capacitor banks for future, when required.

The new DESN, 2x75/125MVA 230/44kV transformers with 6x44kV feeder breaker positions with 2x44kV spare feeder positions, is proposed to be located at the Oshawa Area Junction in the municipality of Clarington. This junction is on the ROW of the Bowmanville and Cherrywood transmission line corridor illustrated in Figure 7-2. The property is already owned by HONI and it is also the site of the new 500/230kV autotransformer Clarington TS supplied by circuits B540C and B543C. The proposed in-service date for the new DESN has a preliminary cost estimate of $34M including feeders egress to the distribution risers outside the station and will be aligned with Clarington TS which is scheduled for 2018.

Figure 7-2 Enfield TS: Proposed Construction Site

Advantages in proceeding with this particular location are as follows:

- The land proposed has already been purchased as part of the property where Clarington TS will be situated resulting in one less station footprint in the Sub-Region.
- Class EA approval has been already obtained for the construction of new TS on Hydro One land at the Clarington TS site.
- The site is also near new development areas which results in minimizing the length of supply feeders from the station.

7.3 GTA East Load Restoration Assessment

Description

GTA East load restoration need was identified in the NA and IRRP reports as the Working Group recommended that further assessment was required to address the supply shortfall during peak load periods. Previous assessments indicated that for the loss of two transmission elements (B23C/M29C or H24C/H26C), the load interrupted with current circuit configuration during peak periods may exceed load restoration criteria and requires further assessment.

Recommended Plan and Current Status

In collaboration with the Working Group, a detailed report[6] was completed to make a recommendation for the load restoration need identified in the Region. The Working Group's assessments in the report, attached in the Appendix F, concluded the following:

- The historical performance of the circuits over the last 15 years has been excellent with little or no impact on supply reliability and security.

- Working Group is recommending that further investment in motorized disconnect switch (MDS) at this time is not a feasible solution to the load restoration need because the risk and/or probability of loss of load is small based on past performances. Therefore, no further action is required at this time.

7.4 Short Circuit Constraint at Cherrywood TS T7/T8

Description

Currently, new DG is restricted from connecting to Cherrywood TS T7/T8 due to short circuit capacity constraints. Veridian Connections Inc., supplied by this station, has indicated that they have several customers that have expressed interest in connecting DG (over 5MW) to Cherrywood TS T7/T8 but are prevented due to the existing restriction. There is an existing 30MW landfill gas generation connection at Cherrywood TS T7/T8 contributing to the short circuit capacity restriction. This generating unit has been shut down and/or has not generated electricity now for more than one year.

Recommended Plan and Current Status

The short circuit capacity is currently held by an earlier landfill generation connection. Although the facility has not been generating and partially dismantled, there is an uncertainty about availability of the short circuit capacity. Hydro One and the IESO will continue to assess this issue to have this capacity reservation released.

[6] GTA East: Load Restoration, Transmission Planning Report, circulated within the Working Group on August 31, 2016

7.5 Long Term Regional Plan

As discussed in Section 5, the electricity demand in GTA East Region is forecasted to grow at 2% annually over the next 10 years. Similar trend is also expected in the long term period where the load is expected to increase by approximately 1.3% annually from year 2026 to 2036. Long term forecast provides a high level insight of how the region may be developing in the future so that near and mid-term plans and ongoing projects in the region are best aligned with potential long term needs and solutions.

No long term needs for the Pickering-Ajax-Whitby Sub-Region were identified in the IRRP. Seaton MTS is expected to supply the Sub-Region's demand adequately over the next two decades. As indicated in the IRRP, official plans by the municipalities expect the lakeshore area in the southern part of Pickering-Ajax-Whitby Sub-Region to grow due to development of high rise residential and commercial buildings. With Pickering NGS expected to retire by 2024, the 230kV transmission lines can be utilized along with a new step-down transformer station to address capacity needs in the southern part of the Sub-Region.

The current forecast did not consider future Pickering Airport which may have an impact on transformation capacity in the long term. Such potential needs will be monitored and system supply capability will be reviewed in the next planning cycle based on the official plans released by the municipalities.

The demand in Oshawa-Clarington Sub-Region is expected to grow over the long term period. The new Enfield TS will mainly provide relief to Wilson TS by supplying the excess load through distribution load transfer capability. As the demand grows in the northern Oshawa area in the long term, additional transformation capacity may have to be planned for in future. Further review and assessment will commence in next Regional Planning cycle to identify and develop alternatives to address new needs.

8. CONCLUSION AND NEXT STEPS

THIS RIP REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA EAST REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in Table 8-1.

Table 8-1: Regional Plans – Needs Identified in the Regional Planning Process

Need ID	Needs	Timing
I	Additional transformation capacity for Whitby TS T1/T2 27.6kV in Pickering-Ajax-Whitby Sub-Region	2019
II	Additional transformation capacity for Wilson TS T1/T2 & T3/T4 in Oshawa-Clarington Sub-Region	Immediately
III	Load Restoration for loss of B23C/M29C or H24C/H26C	No action required at this time
IV	Short Circuit Constraint at Cherrywood TS T7/T8	Pending outcome
V	Additional transformation capacity for Oshawa-Clarington Sub-Region	Long term

Projects, lead responsibility, and timeframes for implementing the wires solutions for the above needs are summarized in Table 8-2 below.

Table 8-2: Regional Plans – Projects, Lead Responsibility, and Planned In-Service Dates

#	Project	Lead Responsibility	I/S Date	Estimated Cost	Mitigated Need ID
1	Seaton MTS and associated line work	Veridian and Hydro One	2019	$43M-$48M	I
2	Enfield TS	OPUCN and Hydro One	2019	$34M	II

GTA East load restoration need, Need ID III, has been reviewed in this Regional Planning cycle and "status quo/do nothing" course of action has been recommended (see Appendix F). Further developments in the Region will be monitored and the need will be reviewed again as part of the next planning cycle.

Hydro One is working with the IESO to explore the best course of action to relieve the short circuit constraint at Cherrywood TS, Need ID IV.

Additional transformation capacity for Oshawa-Clarington Sub-Region, Need ID V, will be reviewed as part of the next Regional Planning cycle.

In accordance with the Regional Planning process, the Regional Planning cycle will be triggered at least once within five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

TRANSMISSION PLANNING REPORT

GTA East: Load Restoration

Revision: Final
Date: August 31, 2016

Prepared by: Hydro One Networks Inc.

[This page is intentionally left blank]

Executive Summary

REGION	GTA East (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	June 17, 2016	**END DATE**	August 31, 2016

1. INTRODUCTION

The purpose of this Transmission Planning (TP) report is to undertake a comprehensive assessment of the load restoration need identified in the Needs Assessment (NA) and Integrated Regional Resource Plan (IRRP) and develop a preferred recommendation. The recommendations of this TP report will become part of the Regional Infrastructure Plan (RIP) and is intended to facilitate the regional planning process as set out by Ontario Energy Board's (OEB) in the Transmission System Code (TSC) and the Planning Process Working Group (PPWG) report to the Board.

Based on Section 6 of the NA and IRRP report, the study team recommended that further assessment was required to address the load restoration need during peak load in the GTA East region. The NA and IRRP report indicated that for the loss of two transmission elements (B23C/M29C or H24C/H26C), the load interrupted with current circuit configuration may exceed load restoration criteria and requires further assessment. The IESO led IRRP recommended this need be further assessed in the RIP, to be completed in Q4 2016. This report provides a detailed assessment along with options and the WG recommendation to be included in the RIP report.

2. REGIONAL NEED ADDRESSED IN THIS REPORT

The circuits M29C/B23C and H24C/H26C are on the same tower line in the GTA East Region 230kV corridor. The loss of either pair of circuits during peak load may result in load shortfall/outage exceeding the limits of 150MW and 250MW to be restored within 4 hours and 30 minutes, respectively.

3. OPTIONS CONSIDERED

Hydro One Transmission along with the WG members have considered the following options to addressing the load restoration need:

Option 1 – a) Status quo/Current state
b) Commissioning of Clarington TS by 2018

Option 2 – Install 8 Motorized Disconnect Switches (MDS) on circuits B23C, M29C, H24C, and H26C

See Sections 4 & 5 for detailed assessment.

4. PREFERRED SOLUTION

At this time, B23C, M29C, H24C, and H26C are approximately 120km-300km long and the historical performance since 2000 has been excellent with no relevant outages. With the new Clarington TS in 2018, the line exposure in the region will reduce to only 46km including tap sections. The assessment concluded that

a) The annual carrying cost of the switches is not justified compared to the annual outage cost, and
b) The installation of Motorized Disconnect Switches will not result in significant enhancement to the reliability of the system after the Clarington TS is in service in 2018.

Option 1 is the preferred solution recommended by the WG at this time. Further details of the assessment and justification are provided in Sections 4 & 5.

5. NEXT STEPS

There are no further actions required at this time.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 Region Description and Connection Configuration

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa and parts of Clarington, and other parts of the Durham Region.

Four 230kV circuits (B23C, M29C, H24C, and H26C) emanating east from Cherrywood TS provide local supply to the Region. Whitby TS DESN2, Thornton TS, and other CTS in the Region are supplied by H24C/H26C while Whitby TS DESN1 and Wilson TS are supplied by B23C/M29C.

A new 500/230kV autotransformer station in the GTA East Region within the municipality of Clarington (called Clarington TS) is expected to be in service by 2018. The assessments in this report evaluate the reliability impact of Clarington TS in the region as well as the installation of Motorized Disconnect Switches (MDS). The new Clarington TS will provide additional load meeting capability in the Region and will eliminate any overloading of Cherrywood autotransformers that may result after the retirement of the Pickering Nuclear Generating Station (NGS). The new autotransformer station will consist of two 750MVA, 500/230kV autotransformers and a 230kV switchyard. The 230kV circuits supplying the east GTA will be terminated at Clarington TS. Clarington TS will become the principle supply source for the GTA East Region load. The facilities in the GTA East Region, including the connection to Clarington TS, are depicted in the single line diagram shown in Figure 1[1].

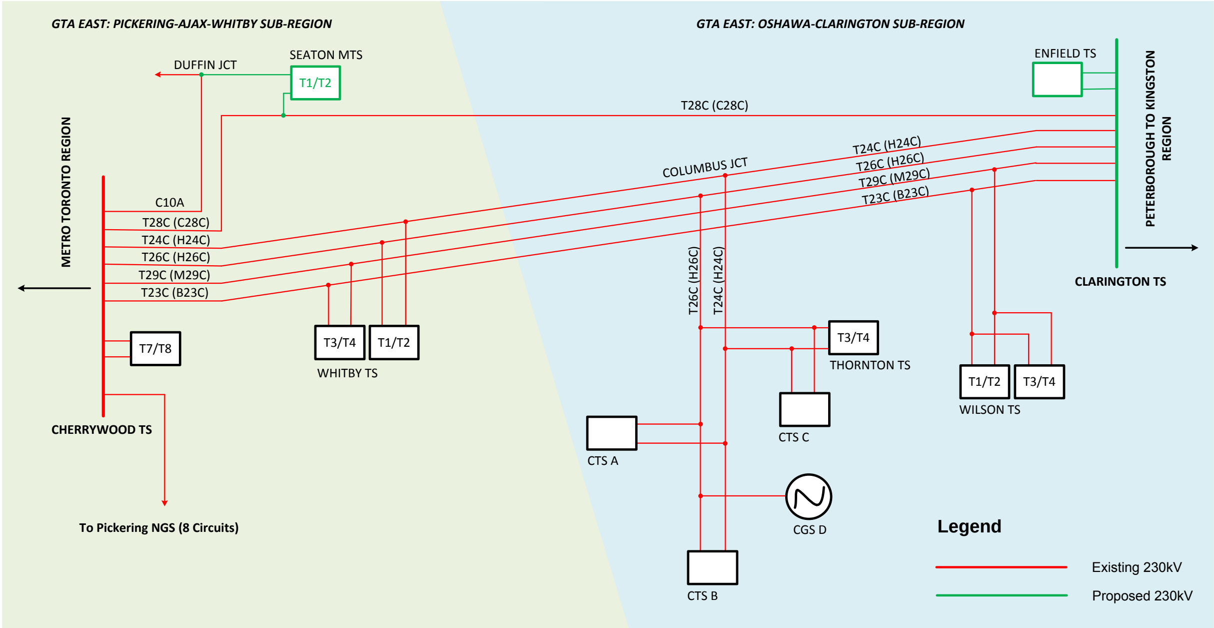

Figure 1 **GTA East Region - Single Line Diagram**

[1] Circuits' nomenclature is shown following the commissioning of Clarington TS (2018) with current convention in parentheses

2 Identified Need

2.1 Load Restoration Criteria

In case of contingencies on the transmission system, the Ontario Resource Transmission Assessment Criteria (ORTAC) provides the load restoration times relative to the amount of load affected. Planned system configuration must not exceed 600MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

a. All loads must be restored within approximately 8 hours.
b. Load interrupted in excess of 150MW must be restored within approximately 4 hours.
c. Load interrupted in excess of 250MW must be restored within approximately 30 minutes.

In addition, ORTAC also provides a provision for exemption from the above restoration criteria on a case-by-case basis.

Figure 2 illustrates the load restoration timelines as discussed above.

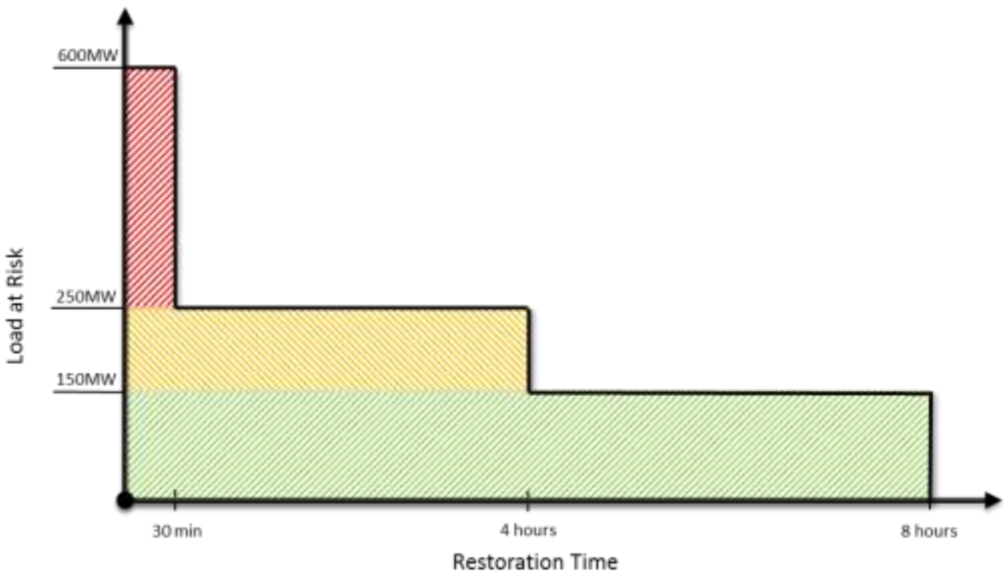

Figure 2 **Load Restoration Criteria**

2.2 Shortfall Need

In 2015, H24C/H26C and M29C/B23C supplied a coincident peak demand of approximately 366MW and 417MW, respectively.

It is expected and assumed that all loads can be restored within 8 hours. However, consistent with the NA and IRRP reports, during peak load periods all loads cannot be restored in the region subsequent of a double circuit contingency between Cherrywood TS and Clarington TS within 30 minutes to 4 hours.

Further findings from the Local Distribution Companies (LDC) in the Region and as reported in the IRRP[2], up to 57MW and 142MW can be restored for customers supplied by H24C/H26C through distribution transfers within 30 minutes and 4 hours, respectively. This leaves the maximum shortfall of 59MW after 30 minutes, and 74MW after 4 hours to be restored from these circuits.

Similarly, for the M29C/B23C, up to 105MW can be restored through distribution transfers within 30 minutes and 257MW within 4 hours for customers supplied by these circuits under the current supply arrangement. This leaves the maximum shortfall of 62MW after 30 minutes, and 10MW after 4 hours to be restored from these circuits.

Table 1 summarizes the 2015 peak demands for each pair of circuit and differentiates between restorable load and the shortage load for 30-minutes and 4-hour periods as discussed above.

Table 1 **Load Restoration/Shortfall in 2015**

2015 Coincident Peak					
Load Pocket	**Actual Demand**	**30-Min Restoration**	**30-Min Restoration Shortfall**	**4-Hour Restoration**	**4-Hour Restoration Shortfall**
H24C/H26C: Whitby TS DESN 1, Thornton TS, and Transmission Connected Customers	366	57	59	142	74
M29C/B23C: Whitby TS DESN2, Wilson TS	417	105	62	257	10

By the end of 2025, the load that cannot be restored increases due to load growth in the region illustrated in Table 2.

Table 2 **Load Restoration/Shortfall in 2025[3]**

2025 Coincident Peak (Net Forecast)					
Load Pocket	**Forecast Demand**	**30-Min Restoration**	**30-Min Restoration Shortfall**	**4-Hour Restoration**	**4-Hour Restoration Shortfall**
H24C/H26C: Whitby TS DESN 1, Thornton TS, and Transmission Connected Customers	445	57	138	142	153
M29C/B23C: Whitby TS DESN2, Wilson TS	425	105	70	257	18

[3] Load forecast is subject to change

2.3 Options considered

An option to build a new 26km of line would have resulted in a cost of more than $75M, obtaining new right-of-way and was not further considered. Following options were further assessed:

Option 1a is status quo and option 1b includes Clarington TS to be in-service by 2018. Accordingly, following two options are further evaluated against each other:

Option 1 – a) Status quo/current state
b) Commissioning of Clarington TS by 2018

Option 2 – Install 8 Motorized Disconnect Switches (MDS) on circuits B23C, M29C, H24C, and H26C

A conceptual configuration of the switches (marked by the red X) is shown for Option 2 in Figure 3.

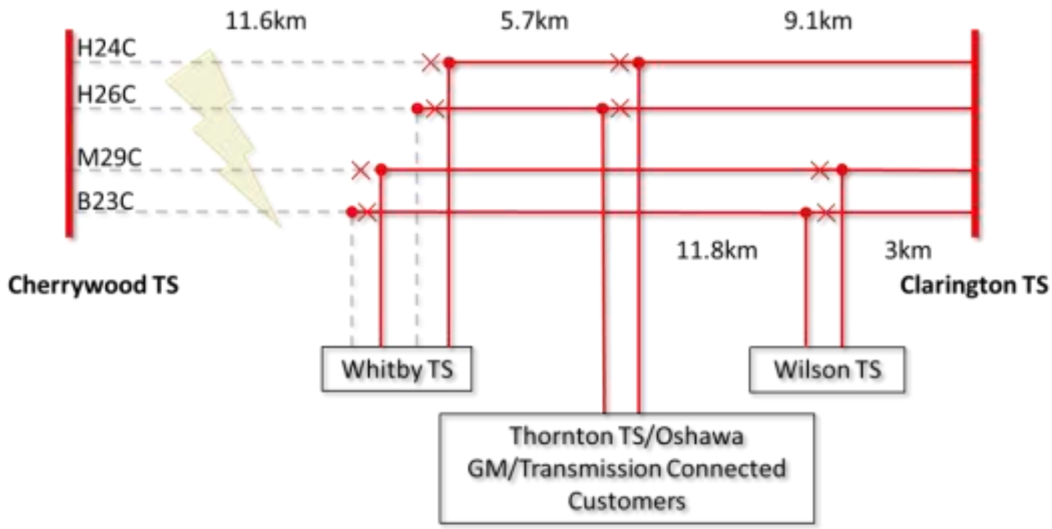

Figure 3 **MDS: Conceptual Configuration**

Similar cases can be shown to isolate faults on other sections of the corridor to restore the loads. It must be noted that although the corridor is protected using 8 MDSs as shown above, the tap offs will still remain unprotected. Further, a common mode fault (refer to section 4) at the tap off line sections will cause an outage regardless of installed switches. With the use of 8 MDS, the optimal locations of the switches are the junction points and 2 switches per circuit as shown in Figure 3.

3 Evaluation Method & Assumptions

The options identified in the previous section were evaluated from the reliability and cost points of view. The reliability indices for overlap outages were evaluated with the help of the AREP Program (Area Reliability Evaluation Program). The reliability for each option is expressed in terms of the frequency and duration of supply interruptions to customers.

Two cost components, one representing the capital cost and one representing the outage cost were evaluated for each option. The two annual costs are given as follows:

Annual cost of carrying charge = C*R,

Where: C – Capital cost of the switches
R – Annual discount rate

The annual outage cost (or risk cost) = F*P*I,

Where: F – Annual duration of load interruption in hours
P – Average kW interrupted including load factor
I – Customer interruption cost ($/KWh)

The following assumptions were made in the assessments:

1. All MDSs are assumed to be perfect (100% reliable).
2. Outages on line tap sections are excluded in common mode outages assessment in section 4.
3. All customer loads are restored within 8 hours for Option 1 and within 30 minutes for Option 2.
4. In case of overlap outages, switching time to isolate the faulted component and restore healthy ones to service is assumed to be one hour.
5. Faults do not occur on lines section where MDSs are located.

The assessment data used in the benefit/cost analysis for all options is provided in Table 3.

Table 3 **Data Used in Reliability Studies**

Assessment Data	
No. of circuit pairs on same towers	27
Total circuit length	551.347km
Circuit years in service	26 years
Distance between Cherrywood TS and Clarington TS	26km
2015 Peak load supplied from B23C and M29C, P	417MW
2015 Peak load supplied from H24C and H26C, P	366MW
Load factor for all load stations	0.6
Customer interruption cost, I	\$10–\$30/kWh[4]
Load restoration time without switches	8 hours
Load restoration time with switches	30 minutes
Cost of one switch (x4 per pair, C)	\$3 Million (\$12 Million)
Annual discount rate, R	5%

[4] Known as Value of Lost Load (VOLL), range is consistent with a Canadian Regulatory Application conducted in 2006 after considering customer composition and provincial GDP – IRRP (2016)

4 Impact of Common Mode Outages

A common mode outage is defined as an event involving two or more outages with the same initiating cause and where the outages are not consequences of each other and occur nearly simultaneously.

4.1 Line Outage Data

The historical common mode outage data for all 230 kV circuits on same structures and east of Cherrywood TS from 1990 to 2015 was used to compute the frequency and duration of common mode line outages. A summary of the common mode line outage events, along with the duration, over the period of 25 years is given in Table 4.

Table 4 **Common Mode Outage Events (from 1990 to 2015)**

Event #	Circuits Involved	Year	Outage Duration	Outage Cause
1	X3H and X4H	1992	927.6h	High winds toppled 16 towers
2	D5A and B5D	1998	0.15h or 9m	Electrical storm
3	B23C and M29C	2008	2.02h	Human error, relay settings
4	L21H and L22H	2011	0.08h or 5m	Relay problems

Only 4 common mode outages have been recorded in eastern Ontario in the last 25 years, of which, only one event is of relevance for this assessment. Hence, Event # 1, in Table 4 is the only one used in calculating the frequency of common mode line outages. This event occurred in November 1992 where adverse weather toppled multiple towers. The other outage events are not relevant to common mode outages because either the outage duration is less than 30 minutes (time assumed for switches to restore power supply to customers) or the outage was preventable or both.

NOTE: Event #1 has never occurred on the GTA East 230kV corridor which is the scope of this assessment but used as a proxy for assessment.

4.2 Reliability Results

The annual frequency of line common mode outages for 230 kV circuits east of Cherrywood TS was calculated by dividing the number of common mode line outages in 25 years by the product of the number of circuit in service years and the total circuit km over the 25 years period. The annual frequency was found to be **0.00007 outages/km** for all of eastern Ontario's 230kV transmission circuits. A low reliability index indicates the circuits in eastern Ontario have performed exceptionally well.

The commissioning of Clarington TS, Option 1b, does not affect the reliability indices for the common mode line outages because of the location of the station at the Oshawa Area Junction. All four 230 kV circuits currently emanate east on single towers from Cherrywood TS to the Oshawa Area junction point. From there on, B23C disperses south towards Belleville TS while the remaining three circuits emanate east on individual towers towards eastern Ontario. Therefore, a common mode line outage on these circuits cannot occur east of Oshawa Area

Junction, future site for Clarington TS.

It is also emphasized that the MDS would have no impact on the frequency of supply interruptions to customers. However, depending upon the location of a permanent fault, the switches can reduce the duration of interruption to customers by isolating the faulted section of the line and restoring the load from the alternative path.

The frequency and duration indices for all options are given in Table 5. The 8 hour restoration time for Option 1a and 1b, without switches, is in accordance with the standard outlined in ORTAC.

Table 5 **Reliability Indices, Common Mode Line Outages**

Options	Annual Frequency of Loss of Supply to any Customer	Duration of loss of Supply in Hours per Occurrence	Annual Duration of Supply Interruptions, F
Option 1a or 1b	0.00182	8	0.01456h or 52.4s
Option 2	0.00182	0.5	0.00091h or 3.3s

4.3 Cost Results

The capital cost and outage cost components were evaluated for all options using the formulae stated earlier. Table 6 shows the results for Circuits B23C and M29C while Table 7 shows the results for Circuits H24C and H26C.

Table 6 **Cost Results, Common Mode Line Outages (B23C/M29C)**

Options	Annual Cost of Carrying Charge in $k	Annual Outage Cost in $k	Total Annual Cost in $k
Option 1a or 1b	$0.00	$36.43-$109.29	$36.43-$109.29
Option 2	$600.00	$2.28-$6.84	$602.28-$606.84

Table 7 **Cost Results, Common Mode Line Outages (H24C/H26C)**

Options	Annual Cost of Carrying Charge in $k	Annual Outage Cost in $k	Total Annual Cost in $k
Option 1a or 1b	$0.00	$31.97-$95.92	$31.97-$95.92
Option 2	$600.00	$2.00-$6.00	$602.00-$606.00

The reliability and cost benefit assessment for the common mode line outages is based on the past 25 years of historical performance of 230kV circuits in eastern Ontario. Based on these findings, the annual reliability index for the GTA East region is only 0.00182 outages. As stated earlier, the installation of switches will not have an impact on the frequency index of events. Rather, as seen in Table 5, the duration of an event is the only dependent variable where the annual duration of an outage is reduced from 52.4s to 3.3s with the installation of switches.

The cost analysis in each option is dependent on the reliability index and is calculated using the assessment data provided in Table 3. Using the cost calculation formulas in Section 3, annual carrying cost of the switches and annual outage costs are calculated for B23C/M29C and

H24C/H26C. The annual carrying cost of the 4 switches per circuit pair is based on the minimum operating period of 20 years while the annual outage costs are based on the duration of outages, calculated from the reliability index, with and without the installation of switches.

The annual cost for just common mode line outages for each pair in the region is approximately \$32k-\$109k while the annual carrying cost of switches, including cost of outages, for each pair is nearly 5-19 times more, \$602k-\$607k. Also, the annual outage cost due to a common mode line outage is calculated on a very small probability of an event occurring. The annual frequency of loss of supply to any customer in the region is only 0.00182 outages, 1 in over 549 years, with or without switches as MDS have no impact on the frequency of supply interruptions.

As shown, the annual reliability and cost benefits from the MDS are insignificant compared to the annual carrying costs of the switches. The installation of switches improves the outage duration, if occurred, from 52.4s to 3.3s for a certain annual investment of over \$1.2M for both pairs of circuits. The annual benefits will still be lower than the carrying costs even if higher values are used for the frequency of common mode line outages. In addition, MDS are assumed to be 100% reliable in this assessment while they introduce a weak link on the system. The reliability and cost analysis show that the installation of MDS is not justifiable.

5 Impact of Overlap Outages

An overlap outage is referred to an event where two or more components are out of service at the same time. The outage initiating causes are different and outages can start at different time. The overlap outage may occur as one of two types; Forced-Forced or Planned-Forced.

5.1 Line Outage Data

The historical outage data from 1990 to 2014 was used to compute the frequency and duration of H24C/H26C line sections and line terminal indices due to forced and planned outages. A reliability model was developed using Area Reliability Evaluation Program (AREP) for both options. The reliability indices were then used to calculate the annual frequency and annual duration of loss of supply to customers. It is expected that circuits B23C/M29C will have similar reliability indices, if not better, due to comparable characteristics and load as circuits H24C/H26C.

5.2 Reliability Results

Currently, the four circuits collectively supply eastern Ontario for 120–300km. In spite of this long distance, the reliability and security of the transmission lines in this part of the province has been exceptional based on the historical performances. Given that these 230kV circuits will now be terminating at Clarington TS, the exposure will reduce to 26km, the region's security and reliability is expected to improve substantially. Table 8 illustrates the reliability indices for the loss of supply to customers considering both types of overlap events: Forced-Forced and Planned-Forced.

Table 8 **Reliability Indices, Overlap Line Outages**

Options	Annual Frequency of Loss of Supply	Annual Duration of Supply Interruptions
Option 1a	0.01	0.12h or 7.02m
Option 1b	0.0008	0.007h or 26.60s
Option 2, Whitby TS DESN 1	0.0001	0.0003h or 1.26s
Option 2, Thornton TS/CTSs	0.0004	0.002h or 8.47s

For each reliability index above, two sets of reliability indices were considered: one due to the overlap of forced outages (Forced-Forced) only and one with the overlap of planned and forced outages (Planned-Forced). In the course of the overlap outages' assessment, it was observed that the Planned-Forced type outages had the dominant impact on the final reliability indices when compared to Forced-Forced type outages.

Further, two types of outages in each set, namely the permanent outages and the switching outages, were computed. In the permanent outage, the supply to customers is restored after repairing the failed components while in the switching outage; the supply to customers is restored by switching off the failed components and restoring the healthy ones to service. The switching time to isolate the faulted component and restore healthy ones to service is assumed to be one hour except in the case of Option 2 where MDSs are expected to operate within 30 minutes.

It is observed in Table 8 that with the commissioning of Clarington TS in 2018, the reliability improves by over 92% while an additional investment in MDSs of over $24 million yields another increment of only 7% to the system reliability. With Clarington TS in service, Option 1b, the reliability indices improve significantly when compared to the reliability of the existing supply system. Also, the annual duration of supply interruption is reduced to just 26.6 seconds from 7 minutes with Clarington TS in the region.

5.3 Cost Results

The capital (carrying) cost and outage cost components were evaluated for the both options using the formulae stated earlier and the results are shown in Table 9. These costs are mainly dependent on the annual duration of supply interruption in Table 8. Since the annual duration of supply interruption in the region is expected to be reduced to merely 26.6s with Clarington TS soon to be in service, the annual expected outage cost has dropped by almost 94%.

Table 9 illustrates that the annual benefits from the MDS are insignificant compared to the annual carrying costs of the switches. The performance of H24C/H26C is expected to be exceptionally good following the commissioning of Clarington TS with an expected annual cost of $15.37k-$46.12k, a very well improvement from the current system and at least 13 times more economical than the annual cost with the switches. With the inclusion of Clarington TS by 2018, the system is projected to be most cost-effective and reliable.

Table 9 **Cost Results, Overlap Line Outages (H24C/H26C)**

Options	Annual Cost of Carrying Charge in $k	Annual Outage Cost in $k	Total Annual Cost in $k
Option 1a	$0.00	$263.52-$790.56	$263.52-$790.56
Option 1b	$0.00	$15.37-$46.12	$15.37-$46.12
Option 2	$600.00	$3.66-$10.97	$603.66-$610.97

6 Conclusion

6.1 Common Mode Outages

The following concluding remarks can be made regarding the impact of the common mode outages:

i) All options have the same frequency of supply interruptions to customers.
ii) Only one common mode outage, relative to this assessment, has occurred in the eastern Ontario in the past 25 years. This event occurred in 1992 due to high winds toppling multiple towers.
iii) The reliability and cost analysis show that it is not justifiable to invest $24M for marginal improvement.

6.2 Overlap Outages

The following concluding remarks can be made regarding the impact of overlap outages:

i) A significant improvement in reliability is observed after the commissioning of Clarington TS in 2018, Option 1b. However, the installation of MDS, Option 2, does not result in a substantial improvement in the reliability indices for an additional cost of approximately $24M.
ii) The result of reliability/cost analysis for circuits B23C/M29C is expected to be similar to H24C/H26C due to similar regional characteristics and loading conditions, therefore, same conclusion can be drawn for both pairs.

6.3 Summary

Based on historical data and a technical analysis on how outages impact the loads supplied by the GTA East 230kV corridor currently, post-Clarington TS, and with MDS, Table 10 illustrates that Clarington TS alone improves the reliability in the region by 77.8% while with additional investment of $24M in MDS, further reliability improvement is insignificant (less than 4%).

Table 10 **Summary of Results**

Options	Total Annual Cost ($k)	Annual Frequency of Interruption	% Reliability Improvement
Option 1a, Current System	$632.16-$1,896.49	0.02364	-
Option 1b, post Clarington TS	$101.28-$303.87	0.00524	77.8%
Option 2, MDS post Clarington TS	$1,211.47-$1,234.37	0.00444	81.2%

In conclusion, the performance of all 4 circuits has been very good over the last 20 years. With Clarington TS in service in 2018 the risk exposure on these circuits will be significantly less; therefore, it is not justifiable to further invest $24M.

Finally, these costs will have to be recovered from the customers or rate payers consistent with the TSC. Furthermore, MDS were considered to be ideal and 100% reliable in the course of this assessment but in reality introduce a weak link in the system.

WG is recommending that based on this assessment, Option 1b is considered to be the most economical and reliable state of the system. No further action is required at this time.

7 Next Steps

Hydro One will continue with the Clarington TS and keep the LDCs informed of any delays with the project. The finding of this study will be included in the GTA East RIP report expected to be completed in Q4 2016.

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE NETWORKS INC. ("HYDRO ONE") AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE ("TSC") REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN FACILITIES THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS OF THE GTA NORTH REGION.

The participants of the RIP Working Group included members from the following organizations:

- Enersource Hydro Mississauga Inc.
- Hydro One Brampton Networks Inc.
- Hydro One Networks Inc. (Distribution)Independent Electricity System Operator
- Newmarket-Tay Power Distribution Ltd.
- PowerStream Inc.
- Toronto Hydro-Electric System Limited
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the OEB's mandated regional planning process for the GTA North Region which consists of the York Sub-Region and the Western Sub-Region. It follows the completion of the York Sub-Region's Integrated Regional Resource Planning ("IRRP") by the IESO in April 2015 and the Western Sub-Region's Needs Assessment ("NA") Study by Hydro One in June 2014.

This RIP provides a consolidated summary of needs and recommended plans for the York Sub-Region over the near-term (up to 5 years) and the mid-term (5 to 10 years). The York Region IRRP has identified the need for additional transformation capacity in Markham, Northern York Region and Vaughan in the mid-term. These mid-term needs are linked to long-term (beyond 10 years) transmission capacity needs.

No needs have been identified over the near-term and mid-term for the Western Sub-Region except for load restoration for the loss of double circuit 230 kV line V43/V44. It is recommended that this need be assessed as part of the IESO led GTA West bulk system planning initiative and as a result is not addressed in this RIP.

The major infrastructure investments planned for the GTA North Region over the near-term, identified in the various phases of the regional planning process, are given in the Table below.

No.	Project	I/S date	Cost
1	Vaughan #4 MTS	Q1 2017	$25M*
2	Holland breakers, disconnect switches and special protection scheme	Q4 2017	$32M
3	Parkway belt switches	Q4 2018	$4-6M

* PowerStream's station cost. Hydro One line connection cost is currently being estimated

The planning is continuing for the mid-term and long-term needs. These needs, and the options to address these them, are being reviewed by the Working Group as part of the community engagement activities currently being led by the IESO and LDCs through the Local Advisory Committee process. The Working Group expects to finalize recommendations to address these and associated long-term transmission needs in an IRRP update currently scheduled for 2017.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA NORTH REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the study with input and consultation with Enersource Hydro Mississauga Inc. ("Enersource"), Hydro One Brampton Networks Inc. ("Hydro One Brampton"), Hydro One Distribution, Newmarket-Tay Power Distribution Ltd. ("NTPDL"), PowerStream Inc. ("PowerStream"), Toronto Hydro-Electric System Limited ("THESL"), and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The GTA North Region includes most of the Regional Municipality of York and parts of the City of Toronto, Brampton, and Mississauga (see Figure 1-1). Electrical supply to the Region is provided through 230 kV transmission circuits, fifteen step-down transformer stations ("TS"), and the York Energy Centre ("YEC") generating station ("GS").

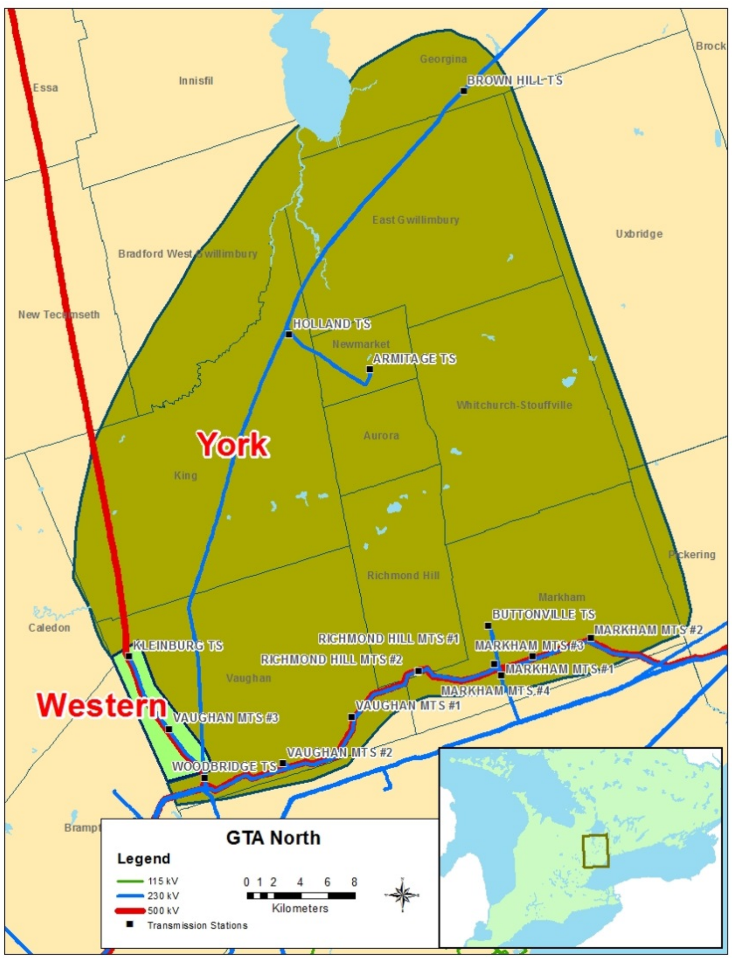

Figure 1-1 GTA North Region

1.1 Scope and Objectives

This RIP report examines the needs in the GTA North Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plan to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of all the needs and relevant plans to address near and mid-term needs (2015 to 2025) identified in previous planning phases (Needs Assessment and Integrated Regional Resource Plan)
- Identification of any new needs over the 2015-2025 period and a wires plan to address them.
- Consideration of long-term needs identified in the York Region IRRP

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the regional needs.
- Section 7 describes the needs and provides alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2 REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led

[1] Also referred to as Needs Screening.

stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- NA, SA, and LP phases of regional planning; and,
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

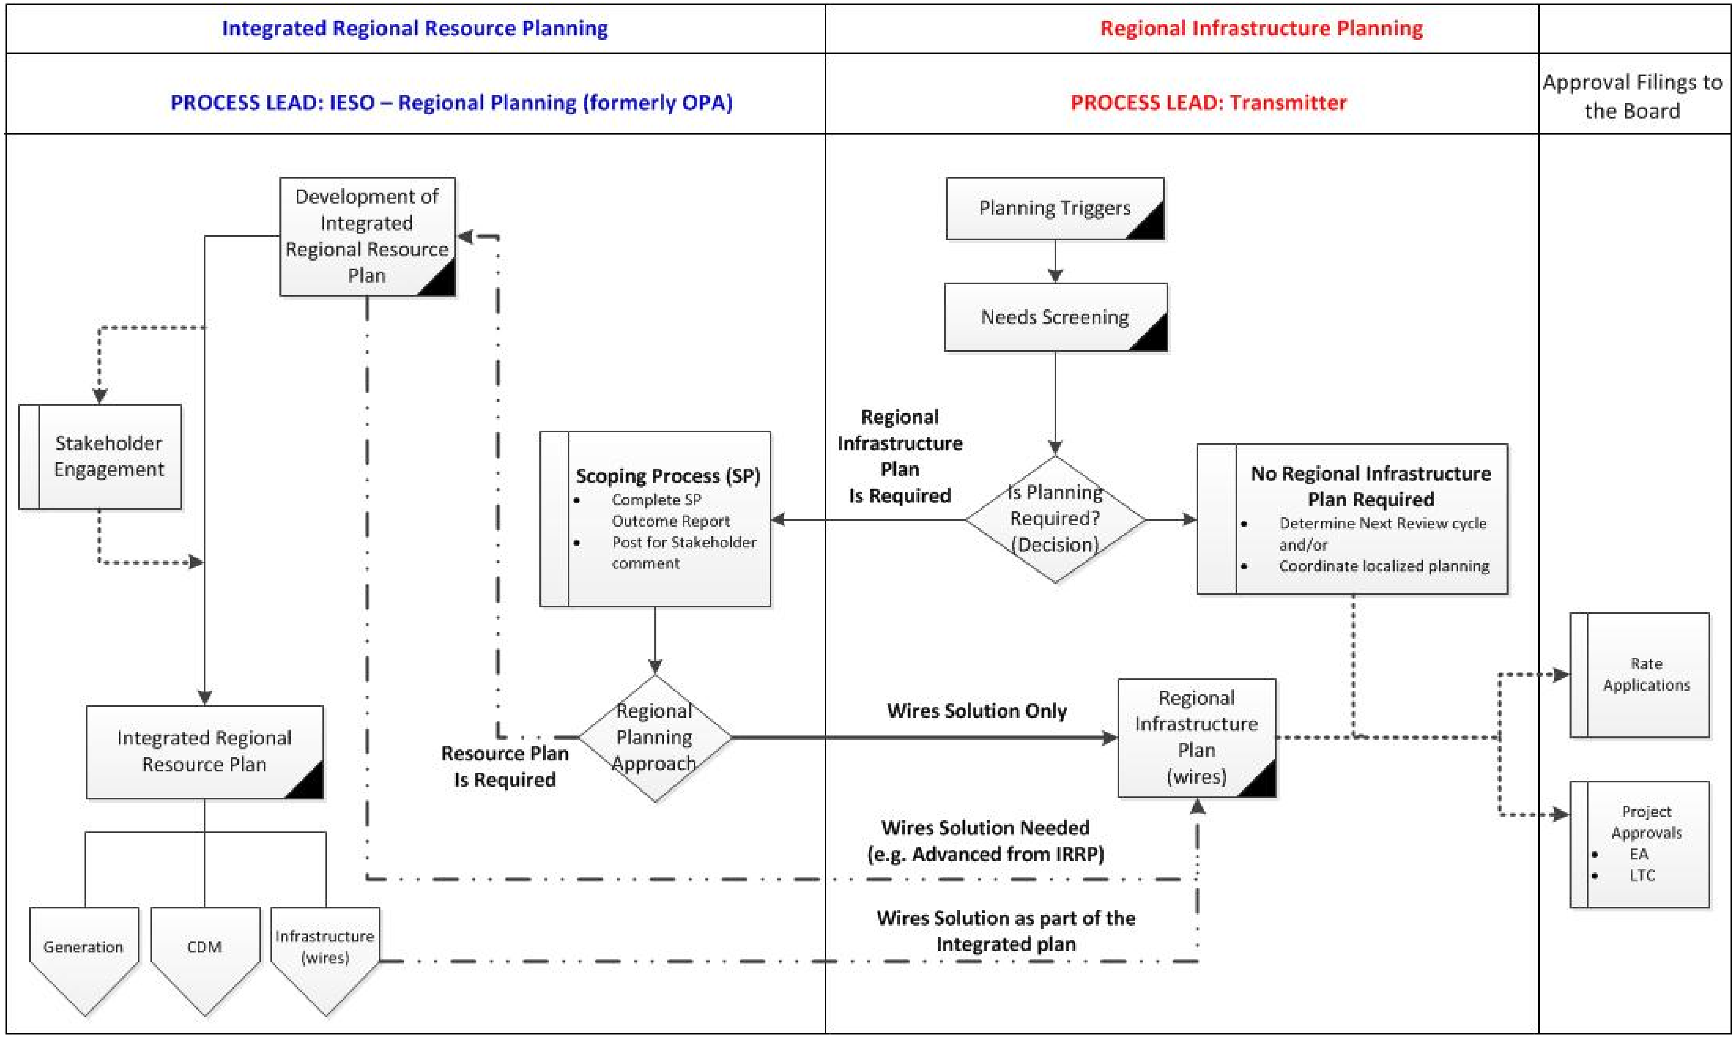

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any DG or CDM programs.
   - Existing area network and capabilities including any bulk system power flow assumptions; and,
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

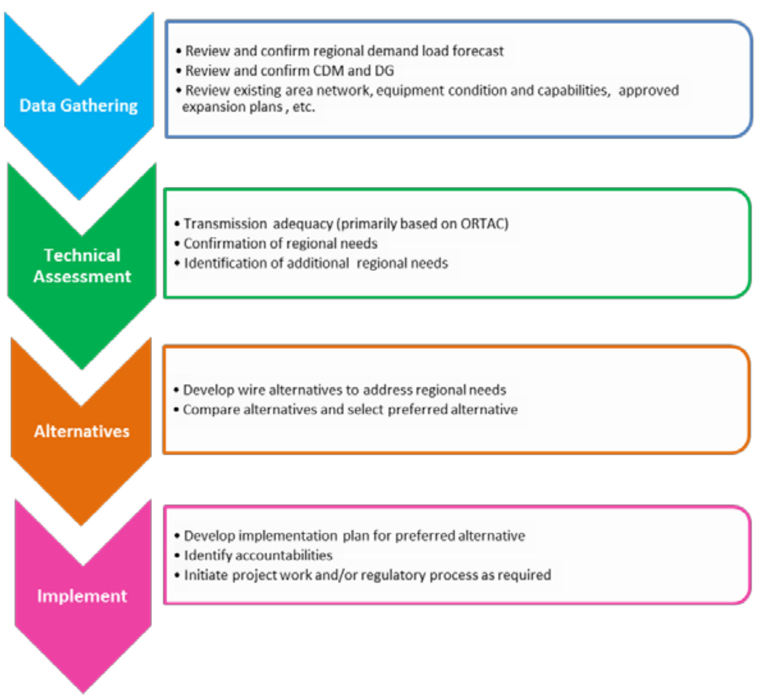

Figure 2-2 RIP Methodology

3 REGIONAL CHARACTERISTICS

THE GTA NORTH REGION IS COMPRISED OF THE YORK SUB-REGION AND THE WESTERN SUB-REGION. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FIFTEEN 230 KV STEP-DOWN TRANSFORMER STATIONS. THE 2015 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 1900MW.

Electrical supply to the GTA North Region is primarily provided from three major 500/230 kV autotransformer stations, namely Claireville TS, Parkway TS, and Cherrywood TS, and a 230 kV transmission network supplying the various step-down transformation stations in the region. Local generation in the Region consists of the 393 MW York Energy Centre connected to the 230 kV circuits B82V/B83V in King Township.

The April 2015 York Region Integrated Regional Resource Plan ("IRRP"), prepared by the IESO in conjunction with Hydro One, PowerStream and Newmarket-Tay Power, focused solely on the York Sub-Region. The June 2014 GTA North Western Sub-Region Needs Assessment report, prepared by Hydro One, considered the Western Sub-Region. A map of the GTA North Region is shown in Figure 3-1 and a single line diagram of the transmission system is shown in Figure 3-2.

3.1 York Sub-Region

The York Sub-Region was identified as a "transitional" region, as planning activities in the region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete, and the regional planning process was considered to be in the IRRP phase. An IRRP for the region was completed in April 2015.

For regional planning purposes, the York Sub-Region is further classified into Northern York Area and Southern York Area to reflect the layout of the region's electricity infrastructure. The Northern York Area encompasses the municipalities of Aurora, Newmarket, King, East Gwillimbury, Whitchurch-Stouffville and Georgina, as well as some load in Simcoe County that is supplied from the same electricity infrastructure. It is supplied by Claireville TS, a 500/230 kV autotransformer station, and three 230 kV transformer stations stepping down the voltage to 44 kV. The York Energy Centre provides a local supply source in Northern York Area. The LDCs supplied in the Northern York Area are Hydro One Distribution, Newmarket-Tay Power Distribution, and PowerStream.

The Southern York Area includes the municipalities of Vaughan, Markham and Richmond Hill. It is supplied by three 500/230 kV autotransformer stations (Claireville TS, Parkway TS, and Cherrywood TS), nine 230 kV transformer stations (includes eight municipal transformer stations) stepping down the voltage to 27.6 kV, and one other direct transmission connected load customer. The LDC supplied in the Southern York Area is PowerStream.

Please see Figure 3-1 and Figure 3-2 for a map and single line diagram of the Sub-Region facilities.

3.2 Western Sub-Region

The Western Sub-Region comprises the Western portion of the municipality of Vaughan. Electrical supply to the sub-region is provided through Claireville TS, a 500/230 kV autotransformer station, and a 230 kV tap (namely, the "Kleinburg tap") that supplies three 230 kV transformer stations (including one municipal transformer station) stepping down the voltage to 44 kV and 27.6 kV. The LDCs directly supplied in the sub-region are PowerStream and Hydro One Distribution. Embedded LDCs supplied in the sub-region include Enersource, Hydro One Brampton and Toronto Hydro.
During the Needs Assessment phase for the Western Sub-Region, a load restoration need for the loss of V43/V44 was identified. It was recommended that a plan to address this need be included in the IESO led GTA West bulk system planning initiative and therefore this need is not addressed in this RIP.

Please see Figure 3-1 and Figure 3-2 for a map and single line diagram of the Sub-Region facilities.

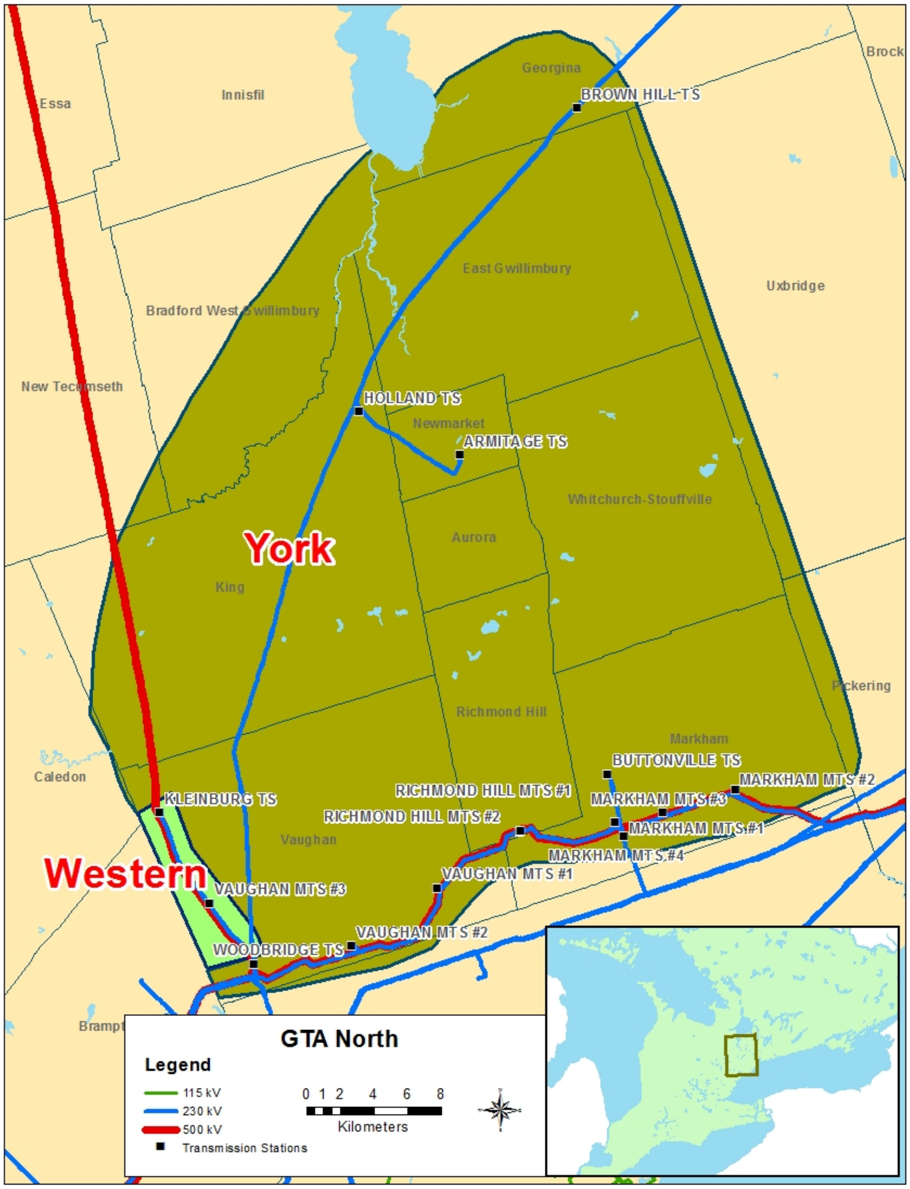

Figure 3-1 GTA North Region – Supply Areas

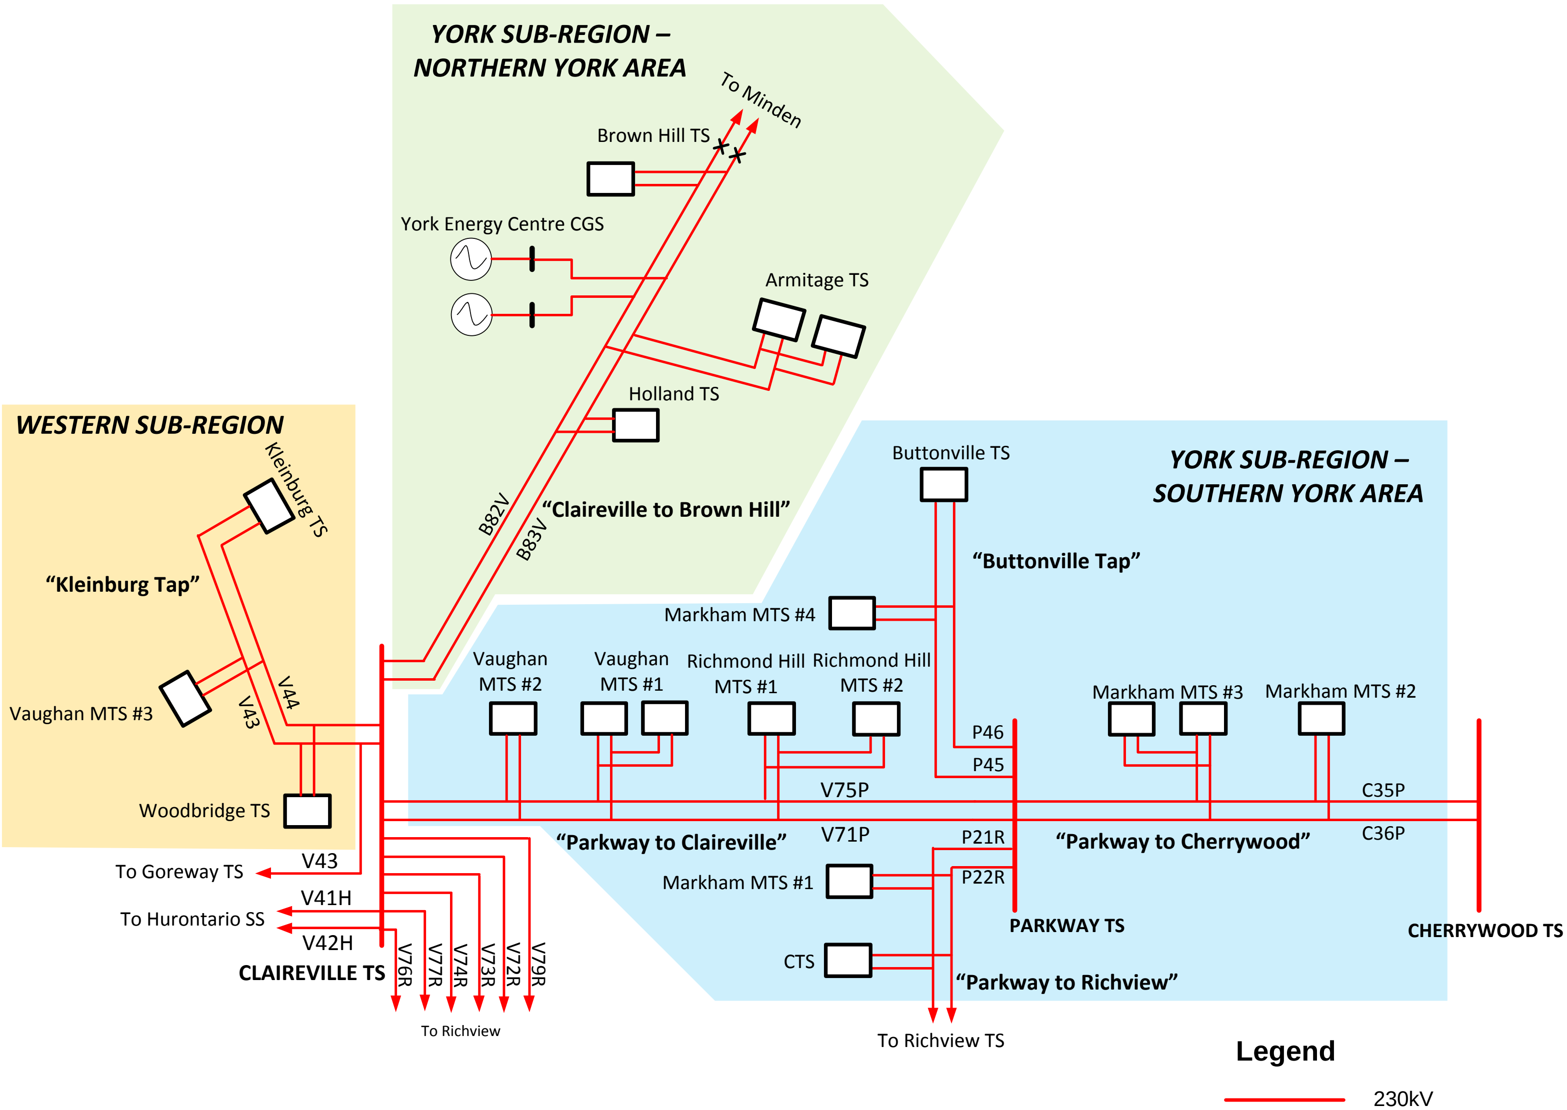

Figure 3-2 GTA North Transmission Single Line Diagram

4 TRANSMISSION FACILITIES COMPLETED OVER THE LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GTA NORTH REGION.

A brief listing of the completed development projects along with their in-service dates over the last 10 years is given below:

- Holland TS and low voltage capacitor banks (2009) – to increase transformation capacity for the Northern York Area.
- Parkway 500-230kV autotransformer station (2006) – to increase transmission supply capacity to GTA North
- Parkway x Richmond Hill 230kV double circuit line (2006) – to improve reliability of supply to Southern York Area
- Connect Markham #4 MTS (2009) – to increase transformation capacity for the Southern York Area.
- Increased the size of the capacitor banks at Armitage TS (2006) – to improve reliability of supply to the Northern York Area.
- Connect the York Energy Centre generation facility (2012) – to provide a local source of supply for the Northern York Area.

The following development projects are currently underway:

- Vaughan MTS #4 (2017) – to increase transformation capacity for the Southern York Area.
- Holland breakers, disconnect switches and special protection scheme (2017) – to increase the transmission supply capacity and load restoration capability of the York Sub-Region.

5 FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA North Region is forecast to increase at an average rate of approximately 2.1% annually up 2020, and 1.8% between 2020 and 2025. The growth rate varies across the Region.

Figure 5-1 shows the GTA North Region extreme summer weather coincident peak net load forecast. The coincident peak net load forecast for the individual stations in the GTA North Region is given in Appendix D. The net load forecast takes into account the expected impacts of conservation programs and distributed generation resources.

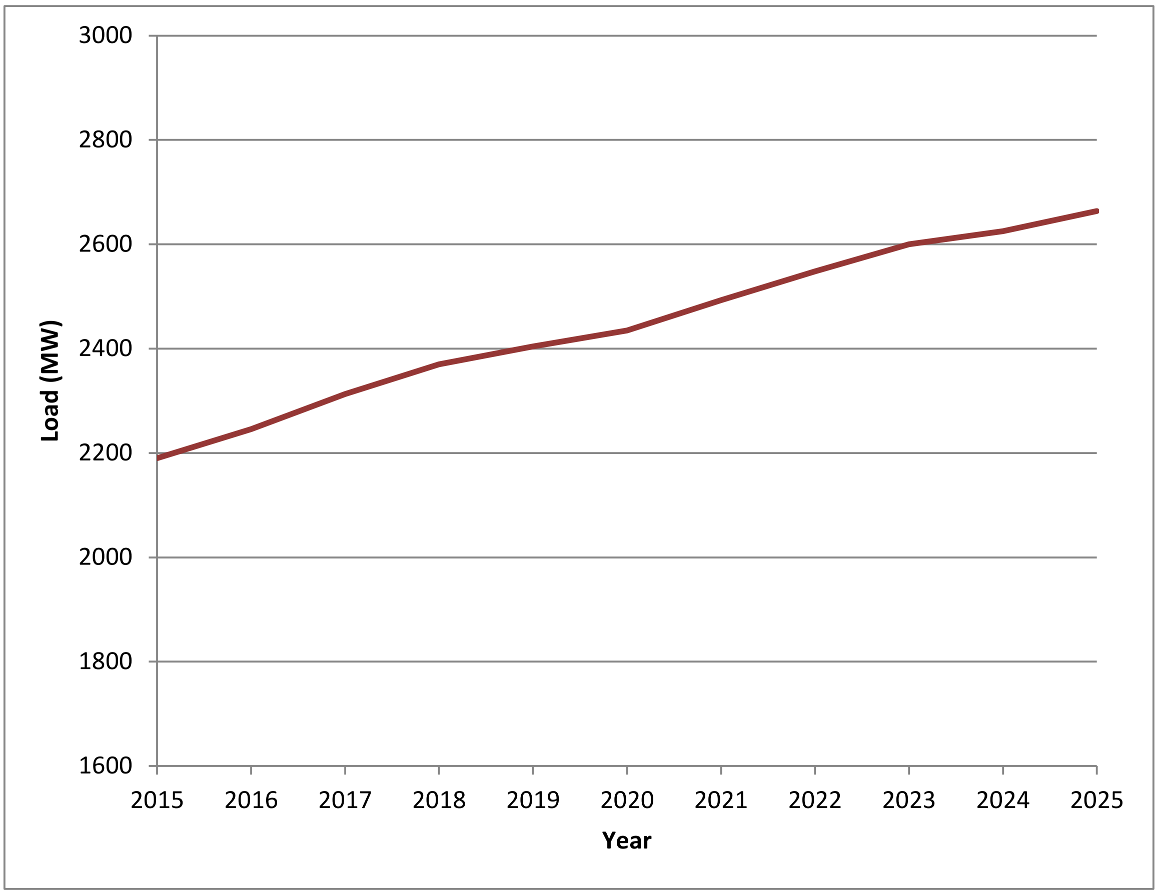

Figure 5-1 GTA North Region Extreme Summer Weather Coincident Peak Net Load Forecast

The station coincident peak net loads used in the RIP are as given in the York Region IRRP for the York Sub-Region[1] and the NA for the Western Sub-Region[2]. RIP Working Group participants confirmed that the load forecast, CDM, and DG information used in the IRRP and NA for the Western Sub-Region was still valid.

5.2 Other Study Assumptions

Further assumptions are as follows:

- The study period for the RIP Assessments is 2015-2025.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor which is consistent with ORTAC[4]. Normal planning supply capacity for transformer stations in this region is determined by the summer 10-Day Limited Time Rating ("LTR").

6 ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2015-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND STEP DOWN TRANSFORMATION STATION FACILITIES SUPPLYING THE GTA NORTH REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM.

Within the current regional planning cycle two regional assessments have been conducted for the GTA North Region; the findings of these studies are input to the RIP:

1) IESO's York Region Integrated Regional Resource Plan – dated April 28, 2015[1]
2) Hydro One's Needs Assessment Report – GTA North – Western Sub-Region – June 27, 2014[2]

The York region IRRP identified a number of regional needs to meet the forecast load demand over the near to mid-term. Due to the immediate nature of the needs the Holland TS Breakers project and the Vaughan #4 MTS project were initiated to provide adequate load supply capability for the York Sub-Region while the York Region IRRP study was still underway. A detailed description and status of the Holland TS Breakers project and other work initiated or planned to meet these needs is given in Section 7.

This RIP reviewed the loading on transmission lines and stations in the GTA North Region assuming the Holland TS Breakers project is in-service using the latest Regional Forecast based on the IRRP load growth scenario as given in Section 5. Sections 6.1- 6.4 present the results of this review and Table 6-1 lists the Region's needs identified in both the IRRP and RIP phases.

Table 6-1 Near and Mid-Term Needs in the GTA North Region

Type	Section	Needs	Timing
Step-down Transformation Capacity	7.1.1	Additional transformation capacity in Vaughan (new Vaughan MTS #4 on circuits B82V/B83V)	2017
	7.1.4	Additional transformation capacity in Markham	2022(3)
	7.1.3	Additional transformation capacity in Vaughan(1)	2023(3)
	7.2.2	Additional transformation capacity in Northern York Area(1)	2023
Transmission Capacity	7.2.1	Capacity of the Claireville to Brown Hill (B82V/B83V) transmission line exceeded	2021
Load Security	7.2.1	Claireville to Brown Hill line (B82V/B83V)	2018
	7.1.2	Parkway to Claireville line (V71P/V75P)	Today
Load Restoration	7.2.1	Claireville to Brown Hill line (B82V/B83V)	Today
	7.1.2	Parkway to Claireville line (V71P/V75P)	Today
	7.3.1	Claireville to Kleinburg line (V43/V44) – restoration need only(2)	Today

(1) There are long-term transmission supply needs associated with new transformation capacity
(2) Restoration need to be assessed as part of the IESO led GTA West bulk system planning initiative
(3) PowerStream is currently reviewing their forecast and has advised that the need date for Markham may change to 2023 and the need date for Vaughan may change to 2026.

6.1 Adequacy of York Sub-Region Facilities

6.1.1 500 and 230 kV Transmission Facilities

All 500 and 230 kV transmission circuits in the GTA North are classified as part of the Bulk Electricity System ("BES"). The 230 kV circuits also serve local area stations within the region. The York Sub-Region is comprised of the following 230 kV circuits. Refer to Figure 3-2.

Southern York Area:

a) Parkway TS to Cherrywood TS 230 kV circuits: C35P and C36P.
b) Parkway TS to Claireville TS 230 kV circuits: V71P and V75P.
c) Parkway TS to Buttonville TS **(**"Buttonville Tap") 230 kV circuits: P45 and P46.
d) Parkway TS to Richview TS 230 kV circuits: P21R and P22R.

Northern York Area:

- Claireville TS to Brown Hill TS 230 kV circuits: B82V and B83V.

The RIP review shows that based on current forecast station loadings and bulk transfers, all 230 kV circuits are expected to be adequate over the study period.

6.1.2 Step down Transformer Station Facilities

There are a total of twelve step-down transformers stations in the York Sub-Region as follows:

Table 6-2 Step-Down Transformer Stations in the York Sub-Region

Northern York Area		
Armitage TS	Brown Hill TS	Holland TS
Southern York Area		
Buttonville TS	Markham MTS#1*	Markham MTS#2*
Markham MTS#3*	Markham MTS#4*	Richmond Hill MTS*
Vaughan MTS#1*	Vaughan MTS#2*	Industrial Customer

*Stations owned by PowerStream

Based on the LTR of these load stations, additional capacity is required in Vaughan in 2017 which will be addressed by Vaughan MTS #4. Based on the forecast in Appendix D, additional capacity is required in Markham as early as 2022, and additional capacity will be needed in both Vaughan and Northern York Area as early as 2023. However, PowerStream has advised that their forecast for Markham and Vaughan is currently under review, and that these need dates may change to 2023 and 2026 respectively.

The station loading in each area and the associated station capacity and need dates are summarized in Table 6-3.

Table 6-3 Adequacy of the Step-Down Transformation Facilities in the York Sub-Region

Area/Supply	Capacity (MW)	2015 Summer Loading (MW)*	Need Date
Northern York Area (Armitage, Holland)	485	430	2023
Northern York Area (Brown Hill)	184	74	-
Southern York Area (Markham/Richmond Hill)	956	833	2022
Southern York Area (Vaughan)	612**	459	2023

* Weather adjusted summer peak as per York Region IRRP

** Includes future capacity provided by Vaughan #4 MTS. It does not include Vaughan MTS #3 which is in the Western Sub-Region

6.2 Adequacy of Western Sub-Region Facilities

The Western Sub-Region is comprised of one 230 kV double circuit line V43/V44 between Claireville TS and Kleinburg TS. Refer to Figure 3-2. The line supplies Kleinburg TS, Vaughan MTS #3, and Woodbridge TS. Loading on the V43/V44 line is adequate over the study period.

6.2.1 Step down Transformation Facilities

There are three step-down transmission connected transformation stations in the York Sub-Region as follows:

Table 6-4 Step-Down Transformer Stations in the Western Sub-Region

Kleinburg TS
Woodbridge TS
Vaughan MTS#3*

*Station owned by PowerStream

The forecast individual station forecast loads are given in Appendix D. Based on the forecast loads these transformer stations are adequate over the study period. The total station capacity and 2015 loads in Western Sub-Region are given in Table 6-5.

Table 6-5 Adequacy of Step-Down Transformation Facilities – Western Sub-Region

Area/Supply	Capacity (MW)	2015 Summer Loading (MW)	2025 Summer Loading (MW)
Western Sub-Region (Vaughan/Kleinburg)	509	394	409

6.3 Other Items Identified During Regional Planning

6.3.1 Load Security and Restoration in the Southern York Area

The York Region IRRP report had identified load security and restoration needs for loss of the Claireville TS to Parkway TS 230 kV double circuit line V71P/V75P. Loading on the Claireville TS to Parkway TS 230 kV double circuit line V71P/V75P exceeds the 600 MW limit as per ORTAC security criteria. Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria. The needs and the Working Group recommendations to address the needs are discussed in more detail in Section 7.1.2.

6.3.2 Load Restoration in Western Sub-Region

The Needs Assessment report for the Western Sub-Region had identified a load restoration need for the loss of the Claireville TS to Kleinburg TS 230 kV double circuit line V43/V44. Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria. The Working Group has reviewed the need and reaffirmed the NA recommendation that this need be considered as part of the IESO led GTA West bulk system planning initiative.

6.4 Long-Term Regional Needs

As shown in Section 6.1.2 additional transformation capacity is required in the mid-term. With continued demand growth, the transmission system supplying these stations is also expected to reach its limits. The York Region IRRP had identified the need to coordinate the long term transmission needs with plans to address the station capacity needs.

The GO Rail Electrification Project is an initiative by Metrolinx to convert several rail corridors from a diesel to an electric-based system. GO's Barrie and Stouffville corridors are part of this plan and it is expected that parts of these rail corridors will be supplied by transmission infrastructure in the GTA North Region. At the time of this RIP the electrification project is still in the planning phase, but the impact of this project on the electrical infrastructure in the GTA North Region will need to be monitored as the plans are developed.

The options to address the transformation capacity needs are being reviewed by the Working Group as part of the community engagement activities currently being led by the IESO and LDCs through a Local Advisory Committee process. The Working Group expects to finalize recommendations to address these and associated long-term transmission needs in an IRRP update currently scheduled for 2017.

7 REGIONAL PLANS

This section discusses the needs, wires alternatives and the current preferred wires solution for addressing the electrical supply needs in the GTA North Region. These needs are listed in Table 6-1 and include needs previously identified in the IRRP for the York Sub-Region[1] and the NA for the Western Sub-Region.[2] Needs for which work is already underway are also included.

The near-term needs include needs that arise over the first five years of the study period (2015 to 2020) and the mid-term needs cover the second half of the study period (2020-2025).

7.1 Southern York Area

7.1.1 Increase Transformation Capacity in Vaughan

7.1.1.1 Description

The load forecast reflects substantial growth around the City of Vaughan, mainly around the northern boundaries, as new developments are being made in the area. As a result, based on the net demand forecast a new transformer station is needed by 2017 to ensure adequate transformation capacity is available. This need was also identified as a near-term need in the 2015 York Region IRRP.

7.1.1.2 Recommended Plan and Current Status

Due to the need to provide transformation capacity by 2017, work on building a new station was initiated by PowerStream while the York Region IRRP was still under way. The IRRP Working Group recommended that the new station connect to the Claireville to Brown Hill lines (230 kV circuits B82V/B83V) approximately 12 km north of Claireville TS.[5] Refer to Figure 7.1.

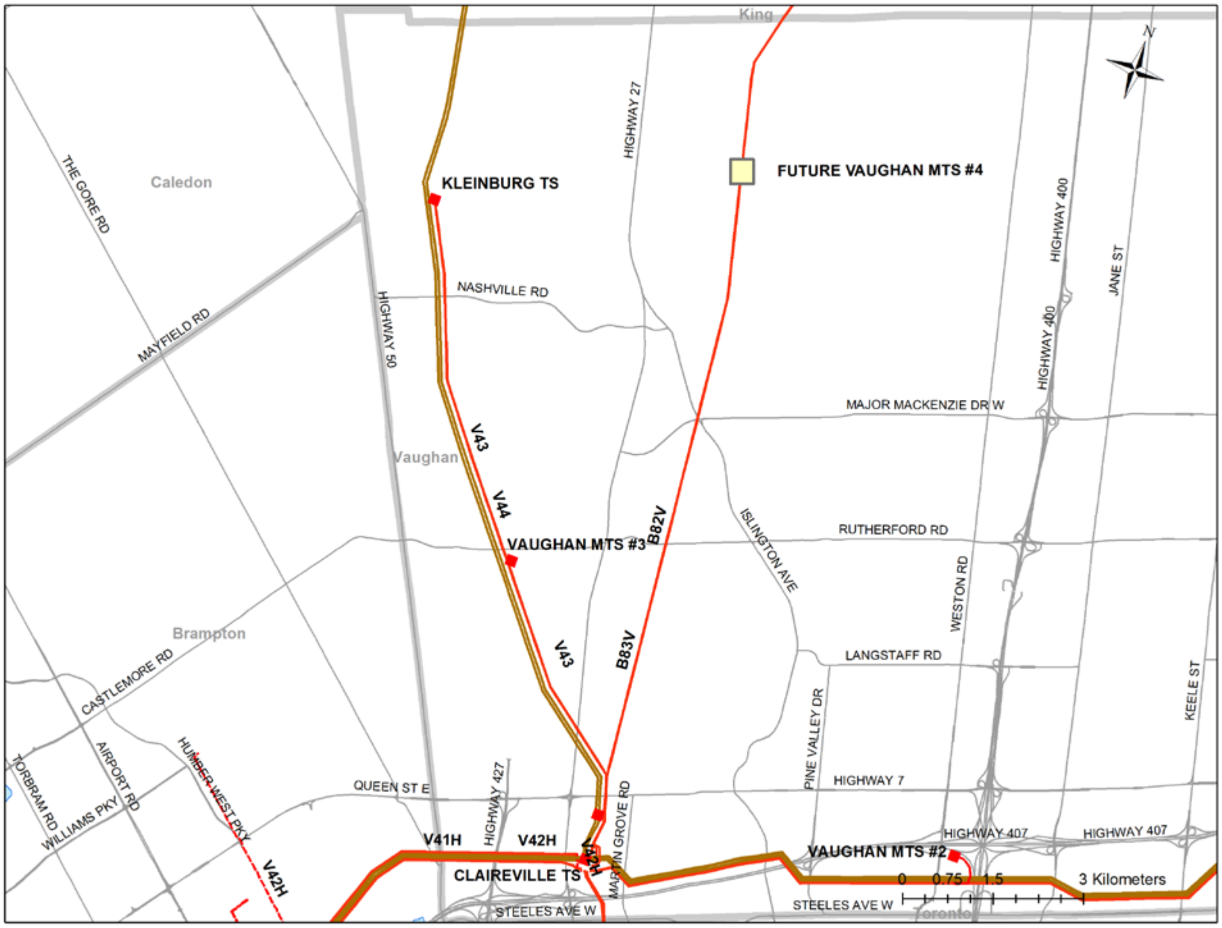

Figure 7-1 Vaughan MTS #4

The new station, Vaughan MTS #4, will provide 153 MW of 27.6 kV transformation capacity and is expected to be in-service by May 2017. Hydro One will construct the line tap to connect the new station to the B82V/B83V circuits.

PowerStream's estimated cost for the station is $25M. The Hydro One line connection cost is currently being estimated. The Hydro One line connection cost will be recovered from rate revenue in accordance with the TSC.

7.1.2 Improve Load Restoration Capability on the Parkway to Claireville Line

7.1.2.1 Description

The Parkway to Claireville line (V71P/V75P) is located on the Parkway Belt and supplies five load stations with a combined load of approximately 700 MW under current summer peak loading conditions. There are two needs identified for this system:

- The load security criteria in ORTAC[4] limits the amount of load that can be interrupted due to the loss of two elements (e.g.: a double circuit line outage) to 600 MW under peak load. On the Parkway to Claireville line, that limit is exceeded.
- The load restoration criteria requires that any load that is interrupted that exceeds 250 MW must be restorable within 30 minutes. At present, this may not be possible on the Parkway to Claireville line under certain operating conditions.

7.1.2.2 Recommended Plan and Current Status

The York Region IRRP recommended the installation of inline switches at the Vaughan MTS #1 junction in order to improve the capability of the system to restore load in the event that both 230 kV circuits V71P/V75P are lost. The switches will not reduce the amount of load that is interrupted, however they will enable Hydro One to quickly isolate the problem and allow the resupply of load to occur expeditiously. This work is covered under the V71P/V75P - Install 230 kV In-line Switches project.

Hydro One has established a project to install the two 230 kV in-line switches onto the V71P/V75P double circuit line with one switch installed on each circuit. The project is currently in the detailed design and estimation phase. The cost of this project is approximately $4-6 million and it is anticipated to be a transmission pool investment. The planned in-service date is May 2018.

7.1.3 Mid-Term Need to Increase Transformation Capacity in Vaughan

7.1.3.1 Description

The planned Vaughan MTS #4 will provide near term transformation capacity for Vaughan beginning in 2017. However, the load forecast shows that additional transformation capacity will be needed in Vaughan as early as 2023. There isn't sufficient transmission capacity available to supply another transformation station on the Claireville to Brown Hill line. Therefore a plan to increase transmission capacity to the area will be required before a plan for a new transformation station can be committed.

7.1.3.2 Recommended Plan and Current Status

Given the time required to build new transmission facilities, the York Region IRRP[1] had advised that it was necessary to identify a preferred alternative no later than 2018 to address both the transformation capacity need as well as the transmission capacity need. However, PowerStream is currently reviewing their load forecast for Vaughan and has advised that the need date for new transformation capacity may change to 2026. An update to the York Region IRRP is currently scheduled for 2017 to review the need date and develop a preferred plan for building and connecting additional transformation capacity in Vaughan.

7.1.4 Mid-Term Need to Increase Step-Down Transformation Capacity in Markham

7.1.4.1 Description

The step-down transformation capacity in Markham will be exceeded as early as 2022. The York Region IRRP has identified that additional transmission facilities will be required to supply the new station. It is expected that the IESO will continue to explore non-wires options, in addition to wires options, through the IRRP process.

New developments attributable to forecasted load growth in the area are generally further north, away from existing transmission facilities. The ORTAC's[4] load restoration criteria will need to be considered in the further development of any detailed wires options. Non-wires options are beyond the scope of this RIP, but there are two main wires options for supplying a new Markham transformer station.

Option 1 - Connect to 230kV circuits C35P/C36P between Parkway TS and Cherrywood TS
The Parkway to Cherrywood line (C35P/C36P) connects two major bulk transmission stations, Parkway TS and Cherrywood TS, and also supplies load stations Markham MTS #3 (2 stations) and Markham MTS #2. There is transmission capacity available on these circuits to connect another transformer station.

Option 2 – Connect to 230kV double circuit line P45/P46 between Parkway TS and Buttonville TS
The Buttonville Tap (P45/P46) currently supplies two stations, Markham MTS #4 and Buttonville TS radially from Parkway TS. The transmission capacity on these circuits is thermally limited by a section less than 1 km long, so it would be necessary to increase the thermal capacity of these circuits in order to fully supply another station.

Extending the transmission circuits discussed would allow the point of supply to be nearer to the area of expected load growth and therefore reduce the amount of distribution facilities that would be needed.

7.1.4.2 Recommended Plan and Current Status

The existing transmission lines are not near the areas of expected load growth so the additional transmission costs to supply a new station nearer to the load need to be considered alongside the distribution costs. PowerStream estimates the incremental distribution costs for a station supplied by existing transmission lines to be on the order of $10-$50M higher than would be required for a station located nearer to the load.

Given that this need is a mid-term need, the York Region IRRP[1] identified a number of non-wires approaches that may address or defer the need for further transformation capacity. Such alternatives include CDM, DG, large generation and other local community initiatives and further monitoring of the load growth was recommended. In order to have facilities in-service to meet a summer 2022 need, it is recommended to continue wires planning, in addition to other non-wires alternatives, to meet this need and to identify a preferred solution by the end of 2017. This timeline allows approximately 4.5 years for detailed estimating, engineering, approvals, construction and commissioning if a wires option is identified as the preferred alternative. However, PowerStream is currently reviewing their load forecast for Markham and has advised that the need date for new transformation capacity may change to 2023. It is expected that the need date will be reviewed and a preferred solution will be identified in the York Region IRRP update process which is currently scheduled for 2017.

7.2 Northern York Area

7.2.1 Increase Capacity and Load Restoration Capability on Claireville to Brown Hill Line

The transmission capacity, load security and load restoration requirements are near-term needs for the Claireville to Brown Hill line (circuits B82V/B83V). These needs were identified in the 2015 York Region IRRP[1]. The Claireville to Brown Hill transmission line and local generation (York Energy Centre) combined are capable of supplying 600 MW of load. This limit is based on the ORTAC[4] load security criteria, which limits the amount of load that can be lost for two elements out of service to 600 MW. This is the most restrictive limit in this system and therefore defines the amount of load that can be supplied. With continued load growth at the stations supplied by this line as well as the future Vaughan #4 MTS (described in section 7.1), it is expected that load security criteria will be exceeded by 2018 based on the net demand forecast.

The load restoration need is based on the ORTAC[4] load restoration criteria that requires any load lost exceeding 250 MW to be restorable within 30 minutes. Based on the current net peak demand forecast, the loss of the Claireville to Brown Hill line will exceed this threshold and there are insufficient transmission and distribution facilities to restore sufficient load within 30 minutes in order to respect the criteria.

7.2.1.1 Recommended Plan and Current Status

Hydro One is expanding the Holland TS station to include two, 230kV inline circuit breakers and six motorized disconnect switches to increase the transmission capacity as well as the load restoration capability of this system. The project includes a load rejection and generation rejection special protection scheme ("SPS"). The purpose of the SPS is to ensure that the transmission system does not get overloaded following respected contingencies. The IESO (formerly the Ontario Power Authority) stated their support for this project in a letter to Hydro One dated June 14, 2013.[5] The planned in-service date for this project is Q4 2017 at an estimated cost of $32 million. This is anticipated to be a transmission pool cost and LDCs are not expected to pay any contribution.

The station service supply to the York Energy Centre is currently supplied from Holland TS. However, a low-voltage breaker failure event at Holland TS or a double circuit 230 kV contingency can result in an interruption to the station service supply to York Energy Centre and therefore the loss of all generation output until the station service can be restored from the alternate source. The IESO intends to develop a plan to address this issue in the York Region IRRP update currently scheduled for 2017.

7.2.2 Mid-Term Need to Increase Transformation Capacity

Based on the growth forecast for the Northern York Area, the combined loading on Armitage TS and Holland TS will exceed their combined summer 10-Day LTR as early as 2023. There is 44 kV transfer capability between these stations on the distribution system so the timing of the need is based on the combined capability of both stations. The IRRP indicated that the Claireville to Brown Hill circuits do not have sufficient capacity to fully supply another transformation station in Northern York Area after the Vaughan #4 MTS connection and Holland breakers project and therefore there is a long-term need to increase transmission capability to supply a new station. However, as noted in the York Region IRRP, under a low growth scenario in the long term, the demand in Northern York Area will stabilize to within the capacity of existing stations to beyond 2033.

7.2.2.1 Recommended Plan and Current Status

The York Region IRRP[1] identified a number of non-wires alternatives that may address or defer the need for further transformation capacity in Northern York Area. Such alternatives include CDM, DG, large generation and other local community initiatives. However, given that the need date for this area may be as early as 2023, it is necessary to identify a preferred alternative by 2018 that addresses both the transformation capacity need as well as the transmission capacity need. The working group expects to finalize a plan and recommendations to address these needs in an IRRP update currently scheduled for 2017.

7.3 Western Sub-Region

7.3.1 Load Restoration Need for the Claireville to Kleinburg Line

The three stations in this sub-region, Woodbridge TS, Vaughan #3 MTS and Kleinburg TS, are supplied by two radial 230kV circuits, V43 and V44, originating from Claireville TS. Inherent to radial configuration, the loss of these two circuits will interrupt supply to loads and consequently load restoration times as per the ORTAC[4] may not be met. This need was identified during the NA for this sub-region and also in the Northwest GTA IRRP[6] and it was subsequently recommended that this need be addressed in the IESO's GTA West bulk system planning initiative.

7.4 Long Term Future Transmission Corridor to the GTA North Region

The GTA West RIP recommended the establishment of a future-use transmission corridor, to address growth-related needs in the GTA West region. In addition to addressing needs in the GTA West region, development of an eastern portion of this corridor through the City of Vaughan is also a possible option that could address the long-term supply needs identified for York Region. It is therefore recommended that, in the development of the long-term plans for the GTA West and GTA North regions, consideration be given to coordinating solutions to meet the needs of both regions when assessing options for each region individually.

8 CONCLUSIONS AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA NORTH REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in Table 8-1.

Table 8-1: Regional Plans – Needs Identified in the Regional Planning Process

No.	Need Description
I	Vaughan Transformation Capacity (Near Term)
II	Northern York Area Load Security on B82V/B83V
III	Northern York Area Load Restoration on B82V/B83V
IV	Parkway to Claireville – Load Security on V71P/V75P
V	Parkway to Claireville – Load Restoration on V71P/V75P
VI	Markham Transformation Capacity (Mid-term)
VII	Vaughan Transformation Capacity (Mid-term)
VIII	Northern York Area Transformation Capacity (Mid-term)
IX	Kleinburg Tap – Load Restoration on V43/V44

Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the needs are summarized in Table 8-2 below. Investments to address the needs where there is time to make a decision (Needs No. VI, VII, and VIII), will be reviewed and finalized in the next regional planning cycle. Need No. IX will be addressed in the IESO GTA West bulk system planning initiative.

Table 8-2: Regional Plans – Next Steps, Lead Responsibility and Planned In-Service Dates

Id	Project	Next Steps	Lead Responsibility	I/S Date	Estimated Cost	Needs Mitigated
1	Vaughan #4 MTS	LDC to carry out the work	PowerStream	2017	$25M	I
2	Holland Breakers and SPS	Transmitter to carry out the work	Hydro One	2017	$32M	II, III
3	Parkway Belt Switches	Transmitter to carry out the work	Hydro One	2018	$4-6M	V

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. Due to the timing of the mid-term needs, the IRRP proposed that the process be updated in advance of the regular 5-year review schedule. The York Region IRRP is currently scheduled to be updated in 2017.

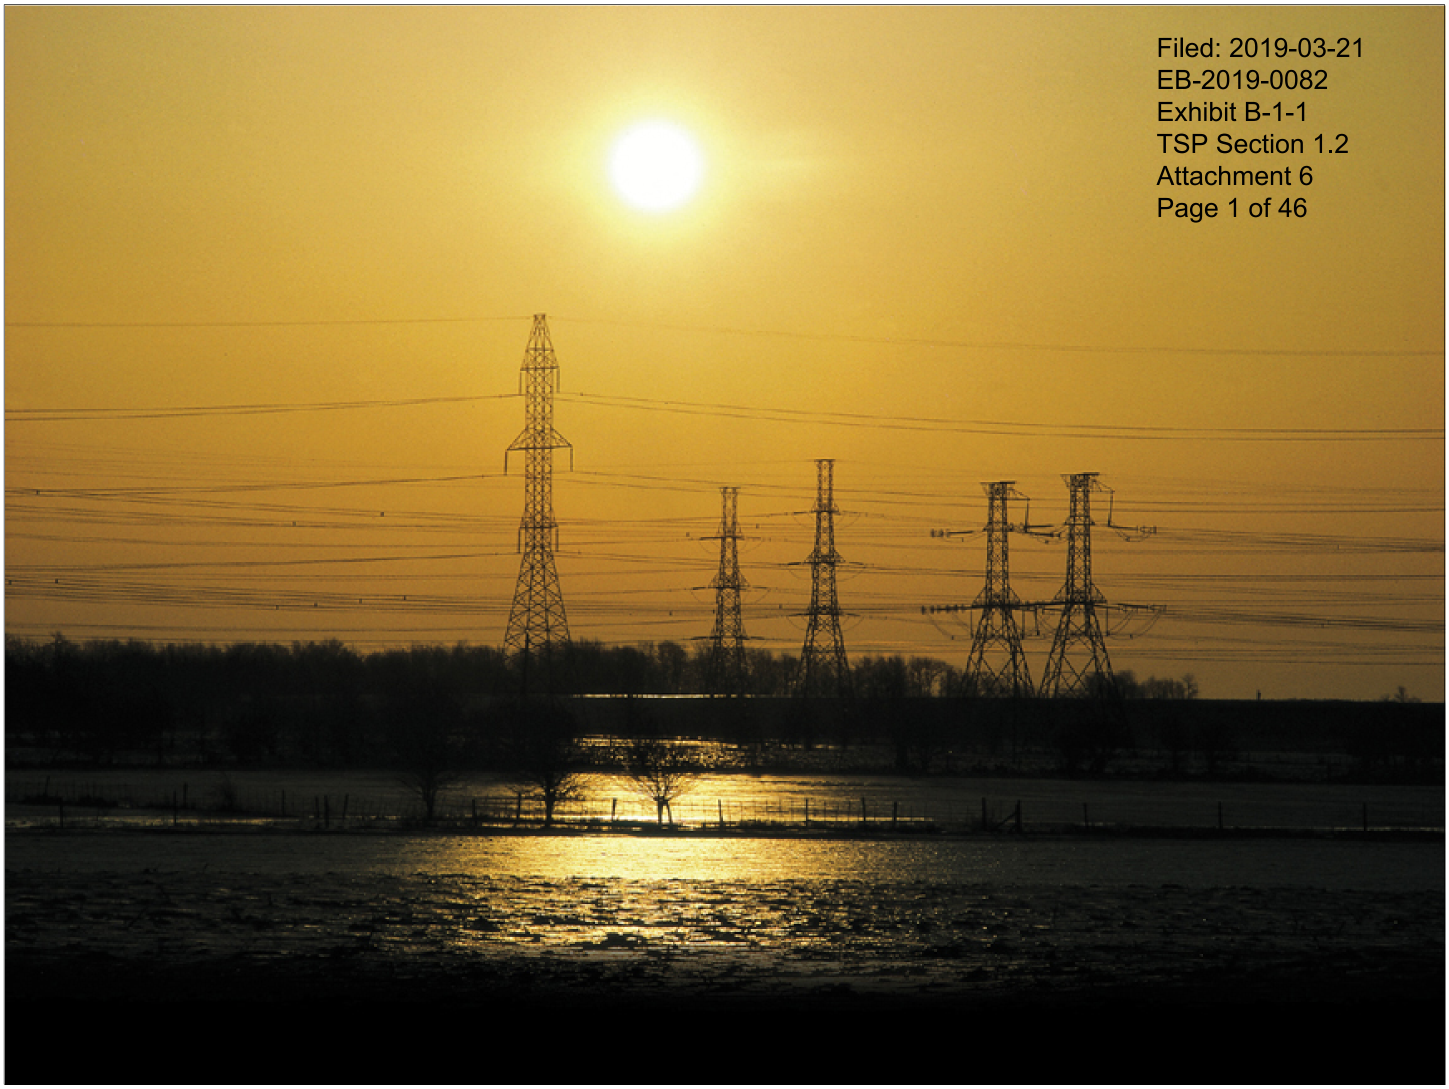
APPENDIX E: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme



GTA West

REGIONAL INFRASTRUCTURE PLAN

January 25, 2016

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Burlington Hydro Electric Inc.
Enersource Hydro Mississauga Inc.
Halton Hills Hydro Inc.
Hydro One Brampton Networks Inc.
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
Milton Hydro Distribution Inc.
Oakville Hydro Electricity Distribution Inc.

[This page is intentionally left blank]

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GTA WEST REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Burlington Hydro Electric Inc.
- Enersource Hydro Mississauga Inc.
- Halton Hills Hydro Inc.
- Hydro One Brampton Networks Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator ("IESO")
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

This RIP is the final phase of the regional planning process and it follows the completion of the Northwest GTA Integrated Regional Resource Plan ("IRRP") in April 2015; and the GTA West Southern Sub-Region's Needs Assessment ("NA") and Scoping Assessment ("SA") in May 2014 and September 2014, respectively.

This RIP provides a consolidated summary of needs and recommended plans for both the Northern Sub-Region and Southern Sub-Region that make up the GTA West Region.

The major infrastructure investments planned for the GTA West Region over the near and medium-term (2016-2025), identified in the various phases of the regional planning process, are given in the table below with anticipated in-service date and estimated cost. Several long-term needs beyond 2026 have been identified, and further assessments are currently underway as part of the IESO Bulk System Study.

No.	Project	I/S Date	Cost
1	Build new Halton Hills Hydro MTS	2018	$19M (1)
2	Build new Halton TS #2	2020	$29M (1)
3	Build new 44/27.6 kV DS to relieve Erindale TS T1/T2	2018-2019	$5M
4	Upgrade (reconductor) circuits H29/H30 (2)	2023-2026	$6.5M

Notes:

(1) Excludes cost for distribution infrastructure
(2) The plan will be reviewed and finalized in the next regional planning cycle

The following needs will be considered in the scope of the Bulk System Study led by the IESO:

- Richview x Trafalgar (R14T/R17T & R19TH/R21TH) circuit capacity need;
- Radial supply to Halton TS (T38/T39B) circuit capacity need;
- Supply security and restoration to several load pockets in GTA West Region.

The IESO's Northwest GTA IRRP has identified that Halton Hills, Caledon, Brampton, and Vaughan area is expected to grow by 849-1132 MW by 2031, as forecast by the Province "Places to Grow" program. A new electricity corridor will be required for additional transmission facilities required to meet this long-term need in the area. The RIP Working Group recommends further assessments to be carried out and complete technical details, layout of high voltage electricity infrastructure no later than Q4 2016. Following this, Environmental Approval and acquisition of land rights would be under taken to ensure that the transmission facilities on this corridor can be placed to meet the needs.

As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years. It is expected that the next planning cycle for this region will start in 2018. If there is a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle can be started earlier to address the need.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA WEST REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) (“Hydro One”) on behalf of the Working Group in accordance with the regional planning process established by the Ontario Energy Board (“OEB”) in 2013. The Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Burlington Hydro Electric Inc.
- Enersource Hydro Mississauga Inc.
- Halton Hills Hydro Inc.
- Hydro One Brampton Networks Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator (“IESO”)
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

The GTA West Region encompasses the municipalities of Brampton, southern Caledon, Halton Hills, Mississauga, Milton, and Oakville. The region includes the area roughly bordered geographically by Highway 27 to the north-east, Highway 427 to the south-east, Regional Road 25 to the west, King Street to the north and Lake Ontario to the south, as shown in Figure 1-1.

Bulk electricity in the region is supplied by Burlington TS from the west, Claireville TS from the north, Richview TS and Manby TS from the east, and 500/230 kV Trafalgar TS autotransformers, and distributed by a network of 230 kV transmission lines and 17 step-down transformer stations. The summer 2015 peak load of the region was approximately 2900 MW.

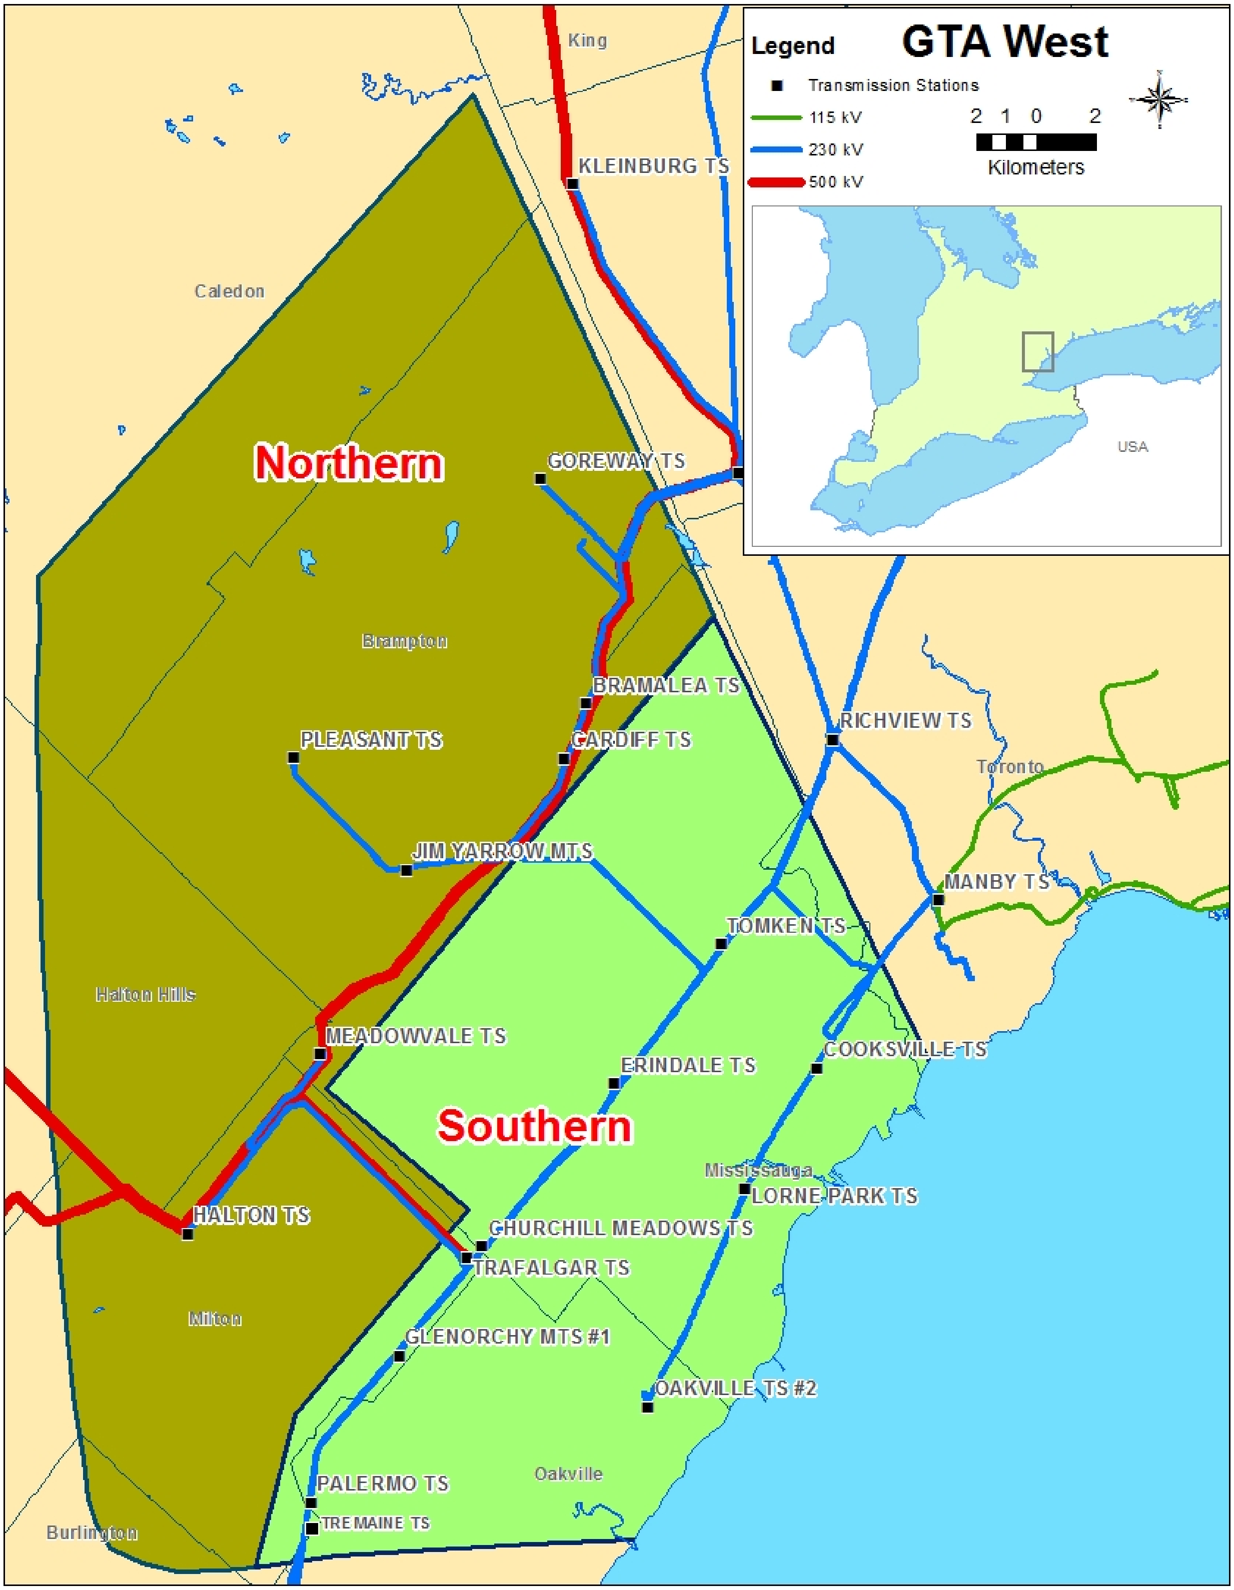

Figure 1-1 GTA West Region Map

1.1 Scope and Objectives

This RIP report examines the needs in the GTA West Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan);
- Identification of any new needs over the 2015-2025 period and wires plans to address these needs based on new and/or updated information;
- Develop a plan to address any longer terms needs identified by the Working Group.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast and study assumptions used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs;
- Section 7 discusses the needs and provides the alternatives and preferred solutions;
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

[1] also referred to as Needs Screening

a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee (LAC) in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

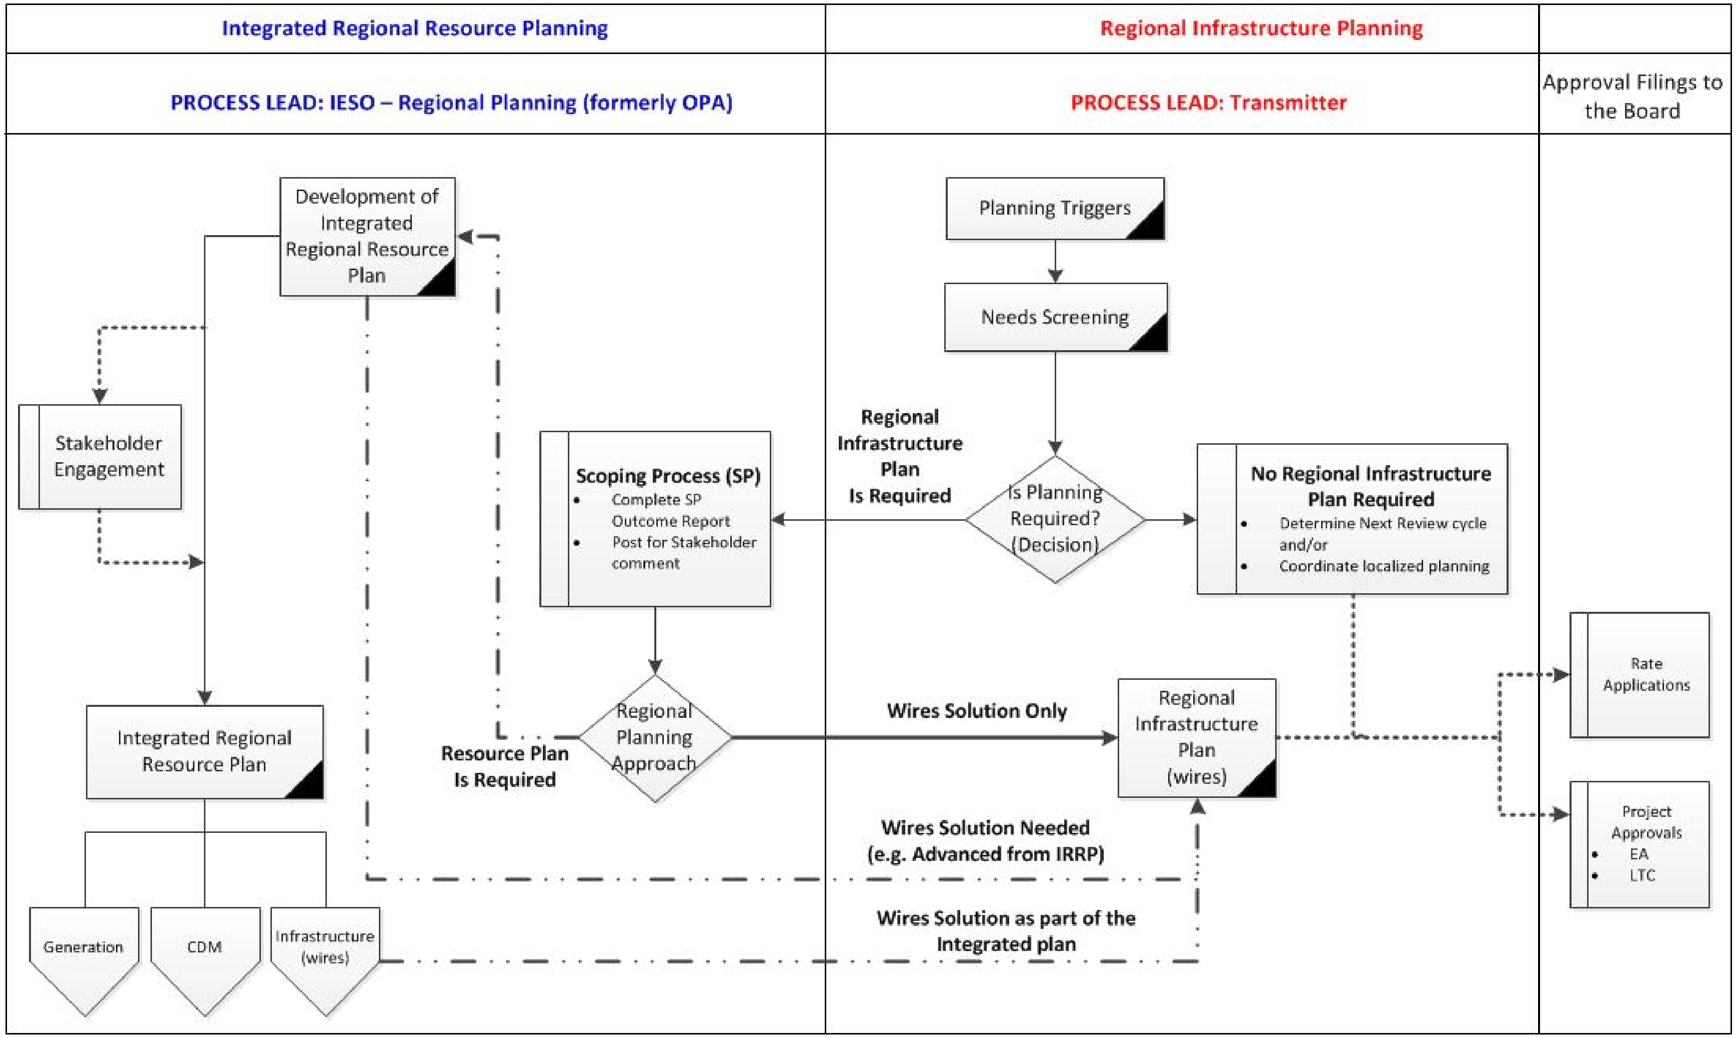

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

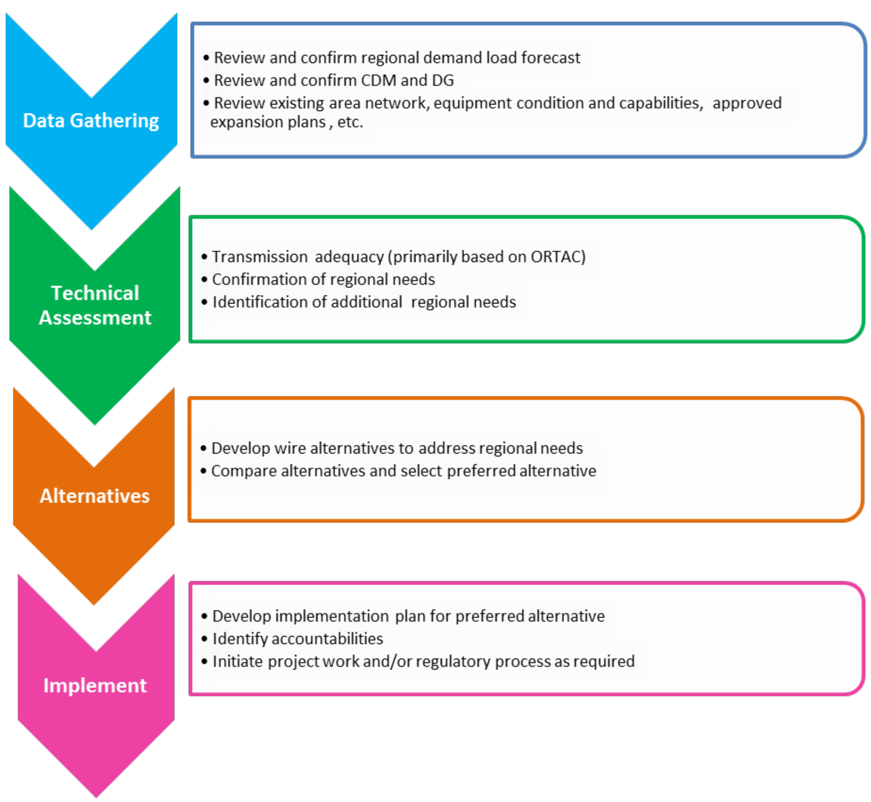

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GTA WEST REGION ENCOMPASSES THE MUNICIPALITIES OF BRAMPTON, SOUTHERN CALEDON, HALTON HILLS, MISSISSAUGA, MILTON, AND OAKVILLE. THE REGION INCLUDES THE AREA ROUGHLY BORDERED GEOGRAPHICALLY BY HIGHWAY 27 TO THE NORTH-EAST, HIGHWAY 427 TO THE SOUTH-EAST, REGIONAL ROAD 25 TO THE WEST, KING STREET TO THE NORTH AND LAKE ONTARIO TO THE SOUTH.

Bulk electricity in the region is supplied by Burlington TS from the west, Claireville TS from the north, Richview TS and Manby TS from the east, and 500/230 kV autotransformers at Trafalgar TS, and distributed by a network of 230 kV transmission lines and 17 step-down transformer stations. Local generation in the region includes the two gas fired plants: Sithe Goreway CGS (839 MW rated capacity) and TCE Halton Hills CGS (683 MW rated capacity). The summer 2015 regional coincidental peak load of the region is approximately 2900 MW.

LDCs supplied from electrical facilities in the GTA West Region are Burlington Hydro Electric Inc., Enersource Hydro Mississauga Inc., Halton Hills Hydro Inc., Hydro One Brampton Networks Inc., Hydro One Networks Inc. (Distribution), Milton Hydro Distribution Inc., and Oakville Hydro Electricity Distribution Inc. The LDCs receive power at the step down transformer stations and distribute it to the end users – industrial, commercial and residential customers.

The April 2015 Northwest GTA IRRP report, prepared by the IESO in conjunction with Hydro One and the LDC, focused on the Northern Sub-Region which included the 230 kV facilities in the northern part of Region. The May 2014 Southern GTA Needs Assessment report, prepared by Hydro One, considered the remainder of the GTA West Region.

For the purpose of regional planning, the GTA West Region is divided into Northern and Southern Sub-Regions. A single line diagram showing the electrical facilities of the GTA West Region, consisting of the two sub-regions, is shown in Figure 3-1. More details regarding transformer stations and transmission lines in the region are provided in Appendix A and B, respectively.

GTA West – Northern Sub-Region

The Northern Sub-Region covers the GTA West Region area north of Highway 407. It is supplied by 230 kV circuits out of Trafalgar TS, Claireville TS and Hurontario SS through seven 230/44 kV or 230/27.6kV step down transformer stations, local generation consist of the Sithe Goreway GS located in Brampton and the TransCanada Halton Hills GS located in Halton Hills, Generation is also connected to the LV buses of Bramalea TS in Brampton.

Enersource, Hydro One Brampton, Milton Hydro and Halton Hills Hydro are the three main Local Distribution Companies in the Sub-Region. They receive power at the step down transformer stations and distribute it to the end use customers.

The GTA West – Northern Sub-Region was identified as a "transitional" sub-region, as planning activities in this sub-region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete, and the regional planning process was considered to be in the IRRP phase. The Northwest GTA IRRP was completed for the Northern Sub-Region in April 2015.

GTA West – Southern Sub-Region

The Southern Sub-Region covers the GTA West Region area south of Highway 407. It is supplied by 230 kV circuits out of Trafalgar TS, Richview TS and Manby TS. There are a total of nine steps down 230/44 kV or 230/27.6 kV step down transformer stations serving the area customers.

Enersource Hydro Mississauga and Oakville Hydro are the main LDCs serving the GTA West - Southern Sub-Region. There is one large industrial customer (Ford Motor Company) in Oakville.

The NA and SA for the Southern Sub-Region were completed in May and September 2014, respectively. A Local Plan has also been developed in this sub-region to address a near-term station capacity need at Erindale TS, further discussed in Section 7.2.

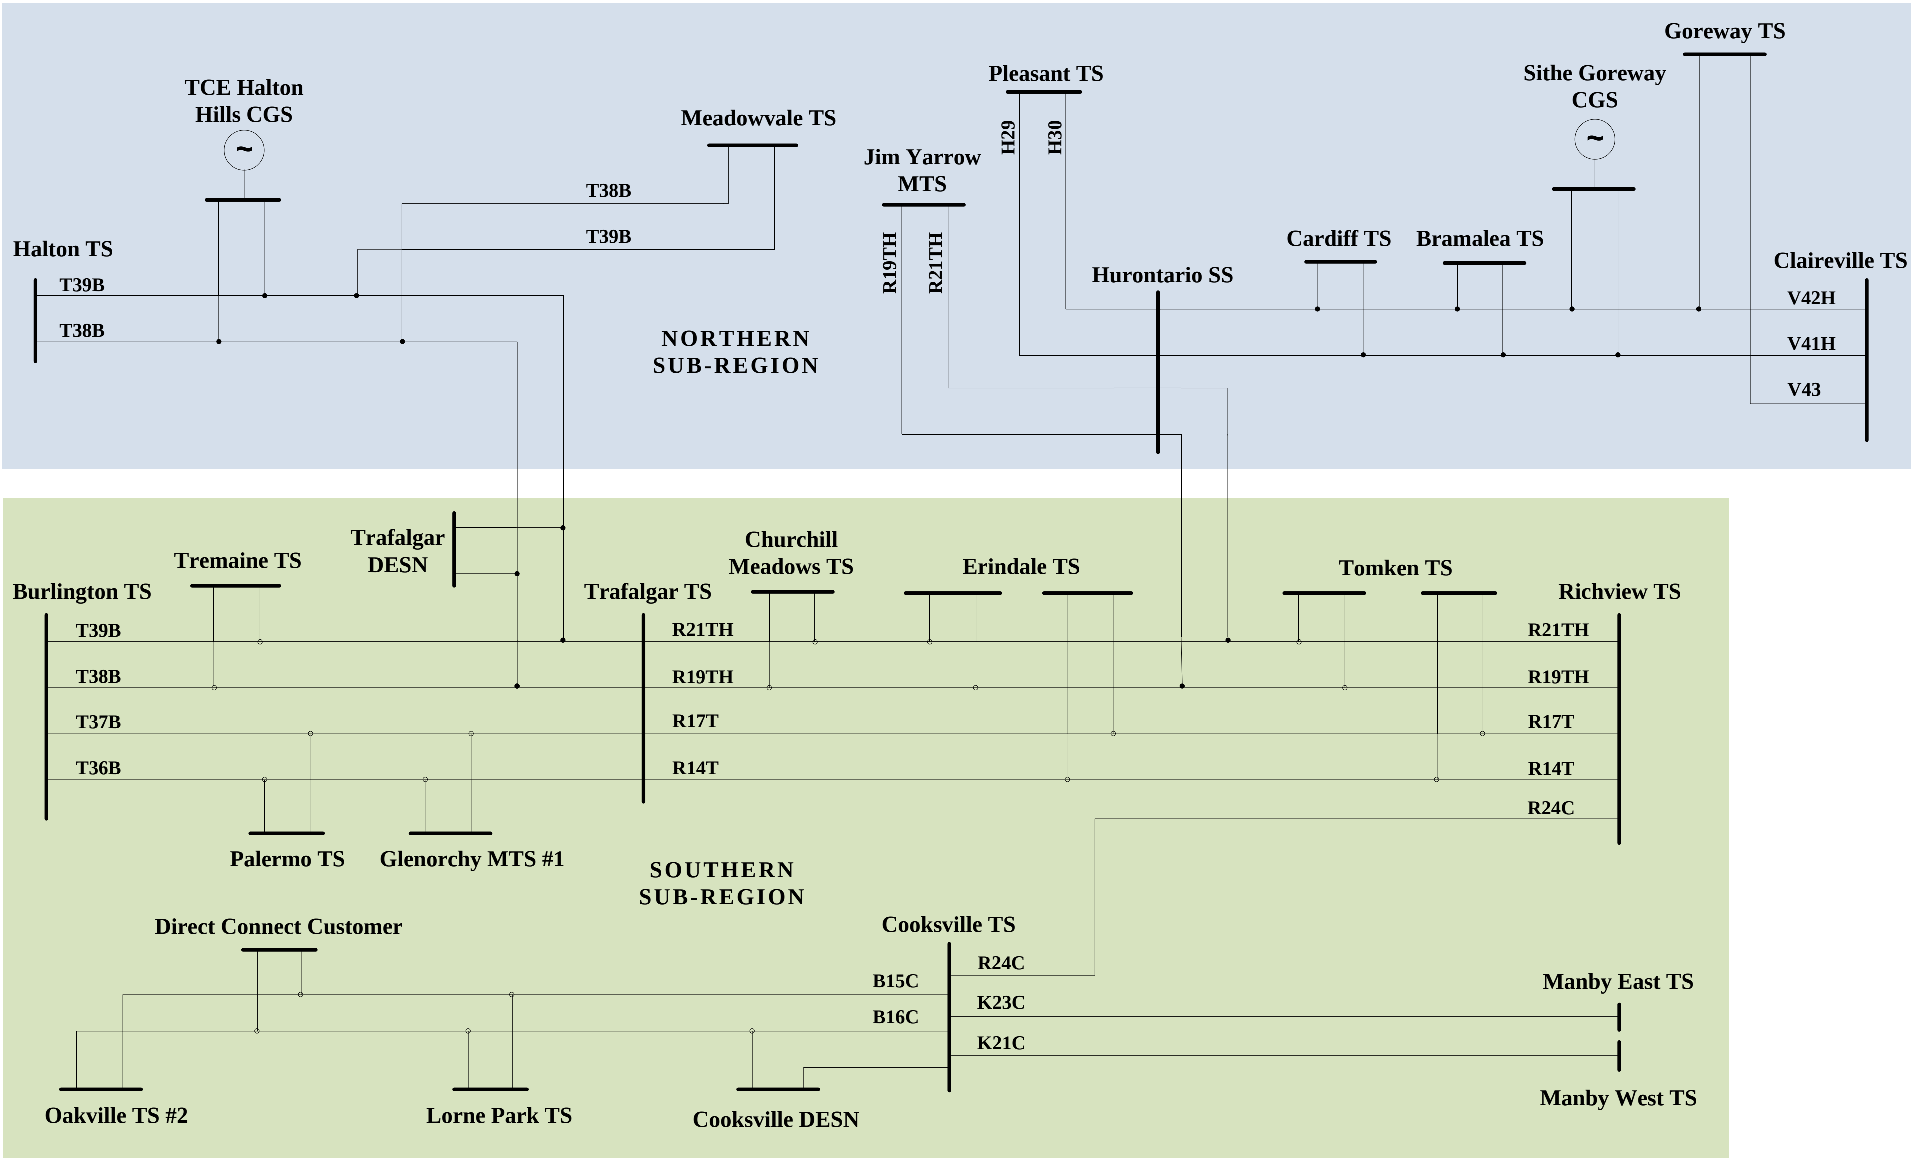

Figure 3-1 GTA West Region Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED AND/OR UNDERWAY IN THE LAST TEN YEARS

IN THE LAST TEN YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY CAPABILITY AND RELIABILITY IN THE GTA WEST REGION.

A brief listing of those projects is given below:

- Cardiff TS (2005) – built a new step down transformer station consisting of two 50/83 MVA transformers in Brampton supplied from 230 kV circuits V41H and V42H. This station provided additional load meeting capability to meet Enersource Hydro Mississauga Inc. requirements.
- Sithe Goreway CGS (2008) – connect a new 839 MW gas-fired combined cycle generation station in Brampton connected to 230 kV circuits V41H and V42H. This generation station provided necessary local power to supply the GTA West Region.
- Halton TS Shunt Capacitor - installed 43.2 MX of shunt capacitor banks at Halton TS 27.6 kV bus for voltage support (2009).
- Churchill Meadows TS (2010) – built a new step down transformer station consisting of two 75/125 MVA transformers in Mississauga supplied from 230 kV circuits R19TH and R21TH. This station provided additional load meeting capability to meet Enersource Hydro Mississauga Inc. requirements.
- Hurontario SS and underground cable work - built a new switching station Hurontario SS, 4.2 km of double circuit 230 kV Line from Hurontario SS to Cardiff TS and 3.3 km of underground cable from Hurontario SS to Jim Yarrow TS (2010). The new switching station and associated line work connects the R19T/R21T circuits and the V42/V43H circuits to provide relief and improved reliability to Pleasant TS and Jim Yarrow MTS.
- Halton Hills CGS (2010) – connected a new 683 MW gas-fired combined cycle generation station in Halton Hills connected to 230 kV circuits T38B and T39B. This generation station provided necessary local power to supply the GTA West Region.
- Glenorchy MTS (2011) – connected new Oakville Hydro-owned Glenorchy MTS to 230 kV circuits T36B and T37B. This station provided additional load meeting capability to meet Oakville Hydro requirements
- Tremaine TS (2012) – built a new step down transformer station consisting of two 75/125 MVA transformers in Burlington supplied from 230 kV circuits T38B and T39B. This station provided additional load meeting capability to meet Burlington Hydro and Milton Hydro requirements.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA West Region is expected to grow at an average rate of approximately 0.8% annually from 2015 to 2025, and 0.5% from 2025 to 2035. The growth rate varies across the region ranging from 1.1% in the Northern Sub Region to 0.5% in the Southern Sub Region over the first 10 years. Longer term is a more uniform growth rate of 0.5% across both Northern and Southern Sub Regions. .

Figure 5-1 shows the GTA West Region load forecast from 2016 to 2035. The forecast shown is the regional coincidental forecast, representing the sum of the load in the area for the 17 step-down transformer stations at the time of the regional peak, and is used to determine any need for additional transmission reinforcements. The coincidental regional peak is forecast to increase from approximately 2900 MW in 2015 to 3300 MW in 2035. Non-coincident forecast for the individual stations in the region is available in Appendix A, and is used to determine any need for station capacity relief.

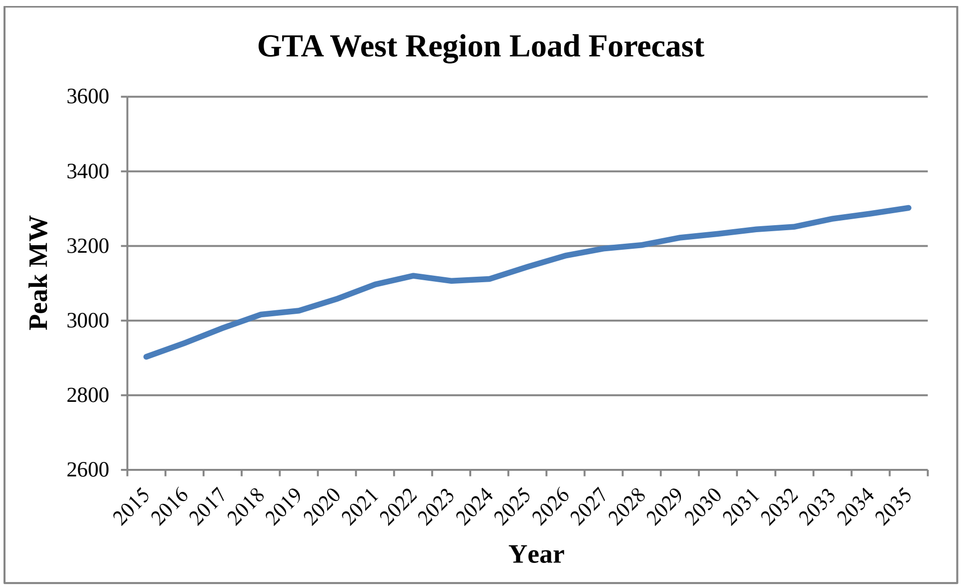

Figure 5-1 GTA West Region Extreme Weather Peak Load Forecast

The regional coincidental load forecast was developed by projecting the 2015 summer peak loads corrected for extreme weather, using the area station growth rates as per the 2015 IESO Northwest GTA IRRP and as per the 2014 Hydro One's Need Assessment Study for the GTA West Southern Sub-Region. The growth rate accounts for CDM measures and connected DG. Details on CDM and connected DG information used in this report are provided in the Northwest GTA IRRP and the Southern Sub-Region's NA, and not repeated in this report.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2015-2035.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR).

6. ADEQUACY OF EXISTING FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND STATION FACILITIES SUPPLYING THE GTA WEST REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE 2016-2025 PERIOD.

Within the current regional planning cycle, three regional assessments have been conducted for the GTA West Region. The findings of these assessments are input to the RIP. These assessments are:

1) The Northwest GTA Integrated Regional Resource Plan (IRRP), April 2015 [1]
2) The GTA West Southern Sub-Region's Needs Assessment (NA) Report, May 2014 [2]
3) The GTA West Southern Sub-Region's Scoping Assessment (SA) Report, September 2014 [3]

The IRRP and NA planning assessments identified a number of regional needs to meet the area forecast load demand over the 2016-2025 period. These regional needs are summarized in Table 6-1. Table 6-1 also includes the longer-term needs (up to 2035) that have been identified in the Northern Sub-Region. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

A review of the loading on the transmission lines and stations in the GTA West Region was also carried out as part of the RIP report. Sections 6.1 to 6.3 present the results of this review.

Table 6-1 Needs Identified in Previous Phases of the GTA West Regional Planning Process

Type	Section	Needs	Timing
Station Capacity	7.1	Halton TS	2018-2020
	7.2	Erindale TS (T1/T2)	Today
Transmission Circuit Capacity	7.3	Richview x Trafalgar (R14T/R17T & R19TH/R21TH)	Within 5 years
	7.4	Radial Supply to Pleasant TS (H29/H30)	2023-2026
	7.5	Radial Supply to Halton TS (T38B/T39B)	2029+
Supply Security	7.6	Supply Security to Halton Radial Pocket (T38B/T39B)	2027
Supply Restoration	7.7	Supply Restoration in Northern Sub-Region (1): - Halton Radial Pocket (T38B/T39B) - Pleasant Radial Pocket (H29/H30) - Cardiff/Bramalea Supply (V41H/V42H)	Today
	7.8	Supply Restoration in Southern Sub-Region: - West of Cooksville (B15C/B16C) - Richview x Trafalgar x Hurontario (R19TH/R21TH) - Richview x Trafalgar (R14T, R17T)	Today
Long-Term Growth	7.9	Pleasant TS (T1/T2) NWGTA Electricity Corridor	2026-2033+

(1) The Northwest GTA IRRP also identified an issue and need to assess "Kleinburg Radial Pocket" supply restoration. This need is being assessed as part of the IESO led Bulk System Study and is not part of this RIP.

6.1 230 kV Transmission Facilities

All 230 kV transmission facilities in the GTA West Region, with the exception of Hurontario SS to Pleasant TS 230 kV circuits H29 and H30 are classified as part of the Bulk Electricity System (BES). A number of these circuits also serve local area stations within the region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (refer to Figure 3-1):

1. Claireville TS to Hurontario SS (230 kV Circuits V41H, V42H, V43) – Supply Bramalea TS, Cardiff TS, and Goreway TS
2. Hurontario SS to Pleasant TS (230 kV Circuits H29, H30) – Supply Pleasant TS
3. Trafalgar TS to Burlington TS, radial tap to Halton TS and Meadowvale TS (230 kV Circuits T38B, T39B) – Supply Halton TS, Meadowvale TS, and Trafalgar DESN
4. Trafalgar TS to Burlington TS (230 kV Circuits T36B, T37B, T38B, T39B) – Supply Glenorchy MTS #1, Palermo TS, and Tremaine TS
5. Richview TS to Trafalgar TS (230 kV Circuits R14T, R17T) – Supply Erindale TS and Tomken TS
6. Richview TS to Trafalgar TS, with tap to Hurontario SS (230 kV Circuits R19TH, R21TH) – Supply Churchill Meadows TS, Erindale TS, Jim Yarrow MTS, and Tomken TS
7. Richview TS and Manby TS to Cooksville TS (230 kV Circuits R24C, K21C, K23C, B15C, B16C) – Supply Cooksville DESN, Ford Oakville CTS, Lorne Park TS, and Oakville TS #2

Based on current forecast station loadings and bulk transfers, the H29/H30 circuits will require reinforcement by 2023-2026. The H29/H30 upgrade will be addressed by Hydro One based on the recommendation stemming from the Northwest GTA IRRP led by the IESO. The Trafalgar to Richview 230 kV circuits (R14T/R17T) will require reinforcement in the near term based on GTA West Southern Sub-Region's NA. This need will be further assessed in the IESO led Bulk System Study.

6.2 500/230 kV Transformation Facilities

All loads are supplied from the 230 kV transmissions system. The primary source of 230 kV supply is the 500/230 kV autotransformers at Trafalgar TS and Claireville TS, as well as 230 kV supply from Burlington TS. Additional support is provided from the 230 kV generation facilities at Halton Hills CGS and Sithe Goreway CGS. Based on the long term forecast in the Northwest GTA IRRP, Trafalgar TS and Claireville TS may require relief in the next 10 years. This need will be studied under the IESO led Bulk System Study.

6.3 Step-Down Transformation Facilities

There are a total of sixteen step-down transformer stations in the GTA West Region. Based on the local station load forecast, Halton TS and Erindale TS would require station capacity relief in the near term, as shown in Table 6-2.

Table 6-2 Step-Down Transformer Stations Requiring Relief

Station	Capacity (MW)	2015 Loading (MW)	Need Date
Halton TS	185.9	176.4	2018
Erindale TS (T1/T2)	181.3	208.3	Now
Pleasant TS (T1/T2)	148.1	124.8	2026-2033 (1)

(1) 2026 under the "Higher Growth" scenario, while 2033 under the "Expected Growth" scenario. Please refer to Northwest GTA IRRP [1]

7. REGIONAL PLANS

THIS SECTION DISCUSSES NEEDS, PRESENTS WIRES ALTERNATIVES AND THE CURRENT PREFERRED WIRES OPTIONS FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE GTA WEST REGION. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE NORTHWEST GTA IRRP AND THE NA FOR THE GTA WEST SOUTHERN SUB-REGION AS WELL AS THE ADEQUACY ASSESSMENT CARRIED OUT AS PART OF THE CURRENT RIP REPORT.

7.1 Halton TS Station Capacity

7.1.1 Description

Halton TS supplies Halton Hills Hydro through 3 feeders and Milton Hydro through 9 feeders at the station. As the load in Halton Hills and Milton continues to grow, the peak load at Halton TS is expected to exceed the station peak load by 2018.

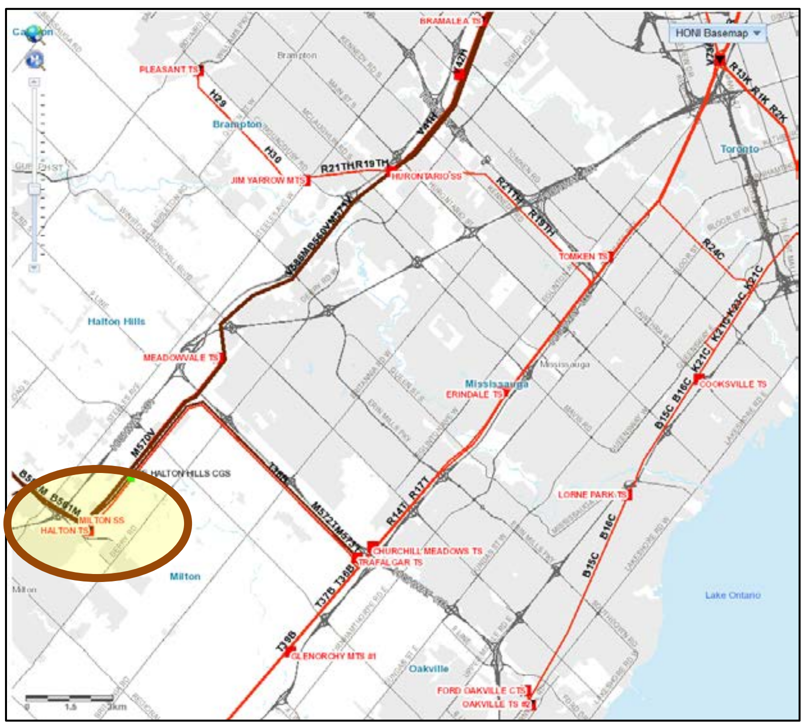

Figure 7-1 Halton TS and Surrounding Areas

7.1.2 Recommended Plan and Current Status

The recommendation of the IRRP is to build two new step-down stations: one to provide supply for Halton Hills Hydro loads and second to supply Milton Hydro load. The Halton Hills Hydro station is expected to be required in 2018, while the Milton Hydro station is expected to be required in 2020.

The IRRP recommends that Halton Hills Hydro proceed to gain the necessary approvals to construct, own, and operate a new step-down station at the Halton Hills Gas Generation facility. Based on technical and economic analysis, the Working Group believes that building this facility is the least-cost option for serving growth within Halton Hills. Currently analysis recommends a targeted in-service date of 2018. Halton Hills Hydro has started a Request for Proposal for the work to construct Halton Hills MTS. The station will consists of two 50/83 MVA transformers with capacity to connect eight distribution feeders. The existing Halton Hills CGS will be expanded to accommodate the HV connection of Halton Hills MTS. There are no transmitter costs for this station. The expected in-service date is spring of 2018. The cost for this station is estimated to be $19 million.

The IRRP recommends Hydro One to initiate engineering work for the development of Halton TS #2 in 2017 (3 year lead-time), at the site of the existing Halton TS, with a tentative in-service date of 2020. The Halton Hills TS #2 will consist of two 75/125 MVA transformers with capacity to connect eight distribution feeders. It will tap to circuits T38B and T39B. The cost for Hydro One to build Halton TS #2 is estimated to be $29 million.

7.2 Erindale TS (T1/T2) Station Capacity

7.2.1 Description

Erindale TS solely supplies Enersource Hydro Mississauga Inc. The existing Erindale TS (T1/T2) DESN load currently exceeds the normal supply capacity. However, there is extra capacity available in the area's 44 kV system that can be utilized by building a step down (44/27.6 kV) distribution station.

Options for providing the required relief were investigated in Local Planning for Erindale TS T1/T2 DESN Capacity Relief [4]. As per the Local Plan, Hydro One and Enersource agreed that this is primarily a distribution planning issue that will involve planning and building a new DS by Enersource to utilize the extra 44 kV station capacity in the area.

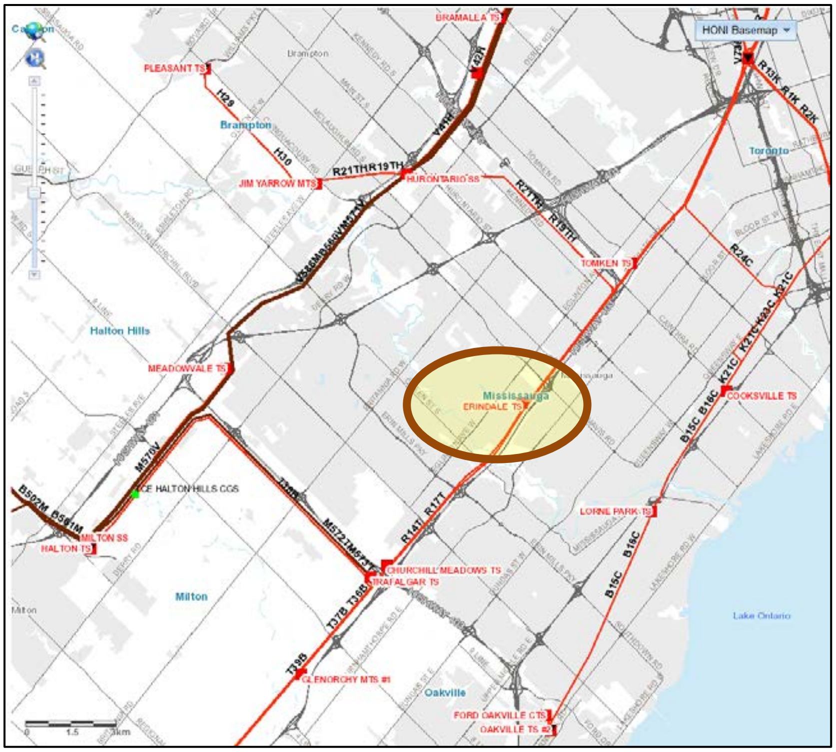

Figure 7-2 Erindale TS and Surrounding Areas

7.2.2 Recommended Plan and Current Status

The proposed DS ("Mini-Britannia MS") is planned to be supplied from Churchill Meadows TS (44 kV system) and provide additional capacity to feed the 27.6 kV load currently supplied by Erindale TS T1/T2. This configuration will reduce over-capacity loading at Erindale TS T1/T2 while balancing the loading capability on 44 kV system via Churchill Meadows TS.

At completion, the substation will house two power transformers (40 MVA capacity), two high voltage switchgears and two low voltage switchgears that will deliver power via four 27.6 kV feeders.

This option is expected to cost $5 million. Under this option, Enersource will build the new DS, own it and recover the costs through the distribution rates. The expected in-service date for the DS is 2018-2019.

7.3 Richview x Trafalgar Transmission Circuit Capacity

7.3.1 Description

As identified in the GTA West Southern Sub-Region's NA, with a single-circuit contingency and high Flow East Towards Toronto (FETT) interface flows, loading on the Richview TS to Trafalgar TS circuits (R14T, R17T, R19TH, R21TH) exceeded their summer long-term emergency ratings in the near-term.

7.3.2 Recommended Plan and Current Status

As these circuits are part of the Bulk Electric System, this need is being further assessed in the IESO-led bulk power system planning.

7.4 Radial Supply to Pleasant TS Transmission Circuit Capacity

7.4.1 Description

Pleasant TS consists of 3 DESNs supplied by 230 kV H29/H30 circuits. Due to growth in load forecasted at Pleasant TS, these circuits are expected to reach their thermal capacity by 2023 at the earliest.

The IRRP process, completed in April 2015, identified the need, discussed alternatives, and recommended a solution to resolve this need.

7.4.2 Recommended Plan and Current Status

The existing conductors used for 230kV circuits H29/H30 going to Pleasant TS are 795.0 kcmil ACSR 26/7 with summer long term emergency rating of 1090 A (at 127°C). They extend 8.5km north from Hurontario SS to Pleasant TS. Based on the study conducted in the Northwest GTA IRRP, this rating limits the maximum load-carrying capacity to approximately 417 MW of load at Pleasant TS.

Preliminary feasibility study shows that the existing towers can support larger conductors. The recommended new conductors would be 1192.5 kcmil ACSR 54/19 with summer long term emergency rating of approximately 1400 A (at 127°C). As per the load flow study conducted in the IRRP, this would supply over 500 MW of load at Pleasant TS. The estimated budgetary cost of this upgrade is about $6.5 million.

The Working Group recommends regularly monitoring the actual load growth and reassessing this issue during the next regional planning cycle.

7.5 Radial Supply to Halton TS Transmission Circuit Capacity

7.5.1 Description

The Northwest GTA IRRP study identified that the thermal capacity of supply circuit to Halton TS from Trafalgar TS to Burlington TS (T38B/T39B) may be exceeded with a single-circuit contingency and Halton Hills GS out of service in the mid-term. However, under this scenario, the ORTAC permits up to 150 MW of load shedding to prevent system overloads. With this control action in place, this need is observed in the long-term in 2029 at the earliest.

7.5.2 Recommended Plan and Current Status

As per the IRRP recommendation, this regional need is being further assessed in the IESO-led bulk power system planning.

7.6 Supply Security to Halton Radial Pocket (T38B/T39B)

7.6.1 Description

As the load connected to T38B/T39B continues to grow, it is expected by 2027 the Halton Radial Pocket will not be able to meet the ORTAC supply security criteria, which states that no more than 600 MW can be interrupted due to a loss of two major power system elements, as shown in Table 7-1.

Table 7-1 Halton Radial Pocket Load Forecast

Year	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027
Halton Radial Pocket Load (MW)	463	471	482	490	491	492	503	512	562	571	585	598	**609**

7.6.2 Recommended Plan and Current Status

The Working Group recommends that the bulk power system study led by IESO account for this supply security issue on T38B/T39B in their planning process.

7.7 Supply Restoration in Northern Sub-Region

The Northwest GTA IRRP study identified that the following circuits are currently at risk of not meeting the supply security and restoration criteria:

Table 7-2 Supply Restoration Need in Northern Sub-Region

Load Pocket	2015 Peak Load (MW)	Load (MW) That Can Be Restored Within 30-min (1)	30-min Restoration Shortfall (MW) (2)
Halton Radial Pocket • Tremaine • Trafalgar DESN • Meadowvale • Halton • Halton Hills Hydro MTS (1) • Halton #2 (1) Supply: T38B/T39B	463	146	**67**
Pleasant Radial Pocket • Pleasant DESNs Supply: H29/H30	359	52	**57**
Bramalea/Cardiff Supply • Bramalea DESNs • Cardiff Supply: V41H/V42H	456	140	**66**

(1) Available 30-min restoration through emergency distribution load transfer following the loss of transmission supply (based on IRRP)
(2) Calculated as follows: Actual Load minus 250 MW minus 30minRestorationCapability. 250 MW is the maximum amount of load not restored within 30-min following loss of two elements.
(3) Halton Hills Hydro MTS and Halton TS #2 are expected to be in-service in 2018 and 2020.

The Northwest GTA IRRP also identified "Kleinburg Radial Pocket" supply restoration need. However, this need will be discussed in more details in the IESO's Bulk System Studies.

As per the IRRP recommendation, all of the above restoration needs are being further assessed in the IESO-led bulk power system planning.

It is expected that with new increased forecasted load at Tremaine TS provided by Milton Hydro and Burlington Hydro, circuitsT38B/T39B Burlington TS to Trafalgar TS will experience higher power flow, and the need date may be moved closer. Therefore, the Working Group recommends that the bulk power system study led by IESO account for this increased flow on T38B/T39B in their planning process.

7.8 Supply Restoration in Southern Sub-Region

The GTA West Southern Sub-Region SA identified that the following circuits are at a risk of not meeting the supply security and restoration criteria in the medium term to long term time frame:

Table 7-3 Supply Restoration Need in Southern Sub-Region

Load Pocket	2015 Peak Load (MW)	Load (MW) That Can Be Restored Within 30-min (1)	30-min Restoration Shortfall (MW) (2)	Load (MW) That Can Be Restored Within 4-hour (1)	4-hour Restoration Shortfall (MW) (3)
West of Cooksville • Oakville #2 • Ford Oakville • Lorne Park Supply: B15C/B16C	304	46	**8**	110	**44**
Richview x Trafalgar x Hurontario • Churchill Meadows • Erindale T5/T6 • Tomken T3/T4 • Jim Yarrow Supply: R19TH/R21TH	555	165	**140**	465	None
Richview x Trafalgar • Erindale T1/T2 • Erindale T3/T4 • Tomken T1/T2 Supply: R14T/R17T	498	115	**133**	390	None

As per the Southern Sub-Region's SA recommendation, all of the above restoration needs are being further assessed in the IESO-led bulk power system planning.

7.9 Long-Term Growth & NWGTA Electricity Corridor Need

Growth projections in the Ontario Governments - Growth Plan for the Greater Golden Horseshoe [5] indicates that the population in Halton Hills, Caledon, Brampton, and Vaughan area is expected to grow significantly over the 20 years period, from 930,000 people in 2011 to 1.5 million people in 2031. Growth plan of this magnitude translates to an overall electrical demand of approximately 849 to 1132 MW by 2031 [1]. Supply electrical demand related to this growth will require new transmission and distribution infrastructure in the area because current electricity infrastructure in the area is limited and at its capacity. Planning and Environmental Approval for a proposed new 400 series Highway, extending from Highway 400 to the Highway 401/407 ETR interchange, has been paused by the Ministry of Transportation. However, opportunities for multi-use transportation/ electricity transmission line corridor must be investigated as new transportation and electricity plans for the area are developed, to maintain consistency with direction outlined in the Provincial Policy Statement.

Existing electricity supply to new developments in the area is technically limited by transmission line and transformer station supply capacity. In addition, there are customer service quality concerns, such as reliability performance and low voltage levels on the LDC's distribution feeders due to the long distance between the locations of new development and existing transformer stations.

Based on the latest load forecast, electrical load at Pleasant TS, which supplies Brampton, is anticipated to exceed its station capacity as early as 2026 [1]. As the result, new station will be required to meet growing electrical needs.

Since a typical 75/125 MVA 230 kV step-down transformer station is capable of supplying up to 170 MW of load, up to 6 new stations in strategic locations could be required to effectively meet load growth in the area over the next 10-20 years. In order to provide adequate supply to these new step-down stations, new 230 kV transmission lines will be required within the general vicinity of the area's load growth centers.

In addition to the need for supply capacity to meet growth, several locations are at risk for not meeting ORTAC criteria following the loss of two transmission elements: Halton radial pocket, Pleasant radial pocket, Bramalea/Cardiff supply, and Kleinburg radial pocket. These needs should also be studied and addressed in a coordinated manner to develop optimal solutions for both GTA North and GTA West Region. As a result, a high degree of integration will be required between regional planning in the two adjacent regions going forward.

Siting a new transmission corridor in the area would provide an alternate supply route to enable continued electrical service when other lines are out of service. Currently it is estimated that over 250 MW of load will not be restored within the timelines prescribed by the criteria. The situation and risk will continue to worsen with continued growth and load will be at higher risk of prolonged power outages following major system contingencies.

An important first phase for providing the required transmission capacity is to identify land / right of ways, which can accommodate economical overhead transmission lines. This includes completing an Environmental Approval followed with an application to the OEB for Leave to Construct (Section 92). The EA process and acquisition of land rights process may take up to five years. Allowing the area to develop without identifying the electricity corridor in municipal plans and not acquiring land rights for transmission corridor now would be significantly arduous after municipal and community development has already taken place without consideration of electricity needs. Identifying and preserving rights-of-way ahead of the forecasted need will help rate payers and municipalities avoid cost associated with underground cables in the future, which is significantly more costly ranging from 5 to 10 times higher than overhead lines.

Continued load growth throughout the GTA, and changing generation patterns across the province, are expected to stress the bulk transmission system's capacity. One option for addressing this need is the addition of a major new 500/230 kV supply point at the existing Milton SS. This new 500/230 kV supply point will provide an additional source to the local network and would need to be supplemented with the incorporation of new 230 kV lines and reconfiguration of the 230 kV system in the area. A new corridor providing new 230 kV transmission lines connecting Milton TS in GTA West and Kleinburg TS in GTA North will allow for better overall bulk system performance in the long-term.

Existing projections of electricity corridor needs can be as early as 2025. The RIP concludes that based on growth projections outlined in the Growth Plan for the Greater Golden Horseshoe [5] a new electricity corridor will be ultimately required to provide additional transmission capacity to meet load growth; provide alternate supply route to various locations to meet restoration criteria; and improve bulk electricity transfer capability.

The RIP Working Group recommends that:

a) The required transmission corridor be identified within the appropriate Regional and Municipal Official Planning documents.

b) Hydro One, the IESO and LDCs undertake immediate action to further assess the location and pace of growth, as well as the related high voltage electrical facilities required for inclusion in a future electricity infrastructure plan. The plan should include but not limited to details with respect to conceptual layout of transmission lines, line terminations, switching stations and the number and approximate location of step-down transformer stations.

c) Following this, Environmental Approval and acquisition of land rights should be under taken to ensure that the transmission facilities on this corridor can be placed to meet the needs.

d) Hydro One, the IESO and LDCs should complete the assessment, technical details, layout of high voltage electricity infrastructure no later than Q4 2016.

8. CONCLUSIONS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA WEST REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in the Table 8-1 below.

Table 8-1 Regional Plans – Needs Identified in the Regional Planning Process

No.	Need Description
I	Halton TS station capacity
II	Erindale TS T1/T2 station capacity
III	Radial supply to Pleasant TS (H29/H30) circuit capacity
IV	Richview x Trafalgar (R14T/R17T & R19TH/R21TH) circuit capacity
V	Radial supply to Halton TS (T38B/T39B) circuit capacity
VI	• Supply security to Halton Radial Pocket • Supply restoration to Halton Radial Pocket, Pleasant Radial Pocket, and Bramalea/Cardiff Supply load pockets • Supply restoration to West of Cooksville, Richview x Trafalgar, and Richview x Trafalgar x Hurontario load pockets
VII	Long term need for a new NWGTA electricity transmission corridor

Next steps, lead responsibility, and timeframes for implementing the wires solutions are summarized in the Table 8-2 below. Investments to address the long-term need where there is time to make a decision (Need III) will be reviewed and finalized in the next regional planning cycle.

Table 8-2 Regional Plans - Next Steps, Lead Responsibility and Plan In-Service Dates

Project	Next Steps	Lead Responsibility	I/S Date	Cost	Needs Mitigated
Build new Halton Hills Hydro MTS	LDC to carry out the work	Halton Hills Hydro	2018	$19M (1)	I
Build new Halton TS #2	Transmitter to carry out the work	Hydro One	2020	$29M (1)	I
Build new 44/27.6 kV DS to relieve Erindale TS T1/T2	LDC to carry out the work	Enersource	2018-2019	$5M	II
Upgrade (reconductor) circuits H29/H30 (2)	Transmitter to carry out the work, and monitor growth	Hydro One	2023-2026	$6.5M	III
• R14T/R17T & R19TH/R21TH circuit capacity need • T38/T39B circuit capacity need • Supply security and restoration need	IESO to carry out Bulk System Study	IESO	TBD	TBD	IV, V, VI
Need for a new transmission corridor in NWGTA	Working Group to complete assessments, technical details & layout by Q4 2016	Hydro One, IESO, LDCs	TBD	TBD	VII

Notes:

(1) Excludes cost for distribution infrastructures
(2) The plan will be reviewed and finalized in the next regional planning cycle

As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years. It is expected that the next planning cycle for this region will start in 2018. If there is a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle can be started earlier to address the need.

Notes:

- Northern (N) Sub-Region's stations load forecast is based on the IRRP [1] "Expected Growth" Scenario.
- Southern (S) Sub-Region's stations load forecast is based on the NA [2] non-coincident stations load forecast.
- Halton Hills Hydro MTS and Halton TS #2 are assumed to be in-service in 2018 and 2020, respectively. Some load from Glenorchy MTS will be transferred to the new Halton TS #2 in 2023, as shown by the corresponding increase and decrease at those stations.
- Load forecast were updated for Palermo TS, Tremaine TS, and Glenorchy MTS based on new information provided by Milton Hydro and Burlington Hydro.

Appendix E. List of Acronyms

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE KITCHENER-WATERLOO-CAMBRIDGE-GUELPH ("KWCG") REGION.

The participants of the RIP Working Group included members from the following organizations:

- Cambridge and North Dumfries Hydro Inc.
- Centre Wellington Hydro
- Guelph Hydro Electric System Inc.
- Halton Hills Hydro One
- Hydro One Distribution
- Hydro One Transmission
- Independent Electricity System Operator
- Kitchener Wilmot Hydro Inc.
- Milton Hydro
- Waterloo North Hydro Inc.
- Wellington North Power Inc.

This RIP provides a consolidated summary of needs and recommended plans for the KWCG Region for the near-term (up to 5 years) and mid-term (5 to 10 years). No long term needs (10 to 20 years) have been identified at this time.

This RIP is the final phase of the regional planning process and it follows the completion of the KWCG Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015.

The major infrastructure investments planned for the KWCG Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the table below.

No.	Project	In-Service Date	Cost
1	Guelph Area Transmission Reinforcement	May 2016	$95 M
2	Arlen MTS: Install Series reactors	May 2016	$0.95 M
3	M20D/M21D – Install 230 kV In-line Switches	May 2017	$6 M
4	Waterloo North Hydro: MTS #4	2024	TBD

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. The Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle may be started earlier to address the need.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE KWCG REGION.

The report was prepared by Hydro One Networks Inc. (“Hydro One”) and documents the results of the joint study carried out by Hydro One, Kitchener-Wilmot Hydro Inc. (“Kitchener-Wilmot Hydro”), Waterloo North Hydro Inc. (“WNH”), Cambridge & North Dumfries Hydro Inc. (“CND”), Guelph Hydro Electric Systems Inc. (“Guelph Hydro”), Hydro One Distribution and the Independent Electricity System Operator (“IESO”) in accordance with the Regional Planning process established by the Ontario Energy Board (“OEB”) in 2013.

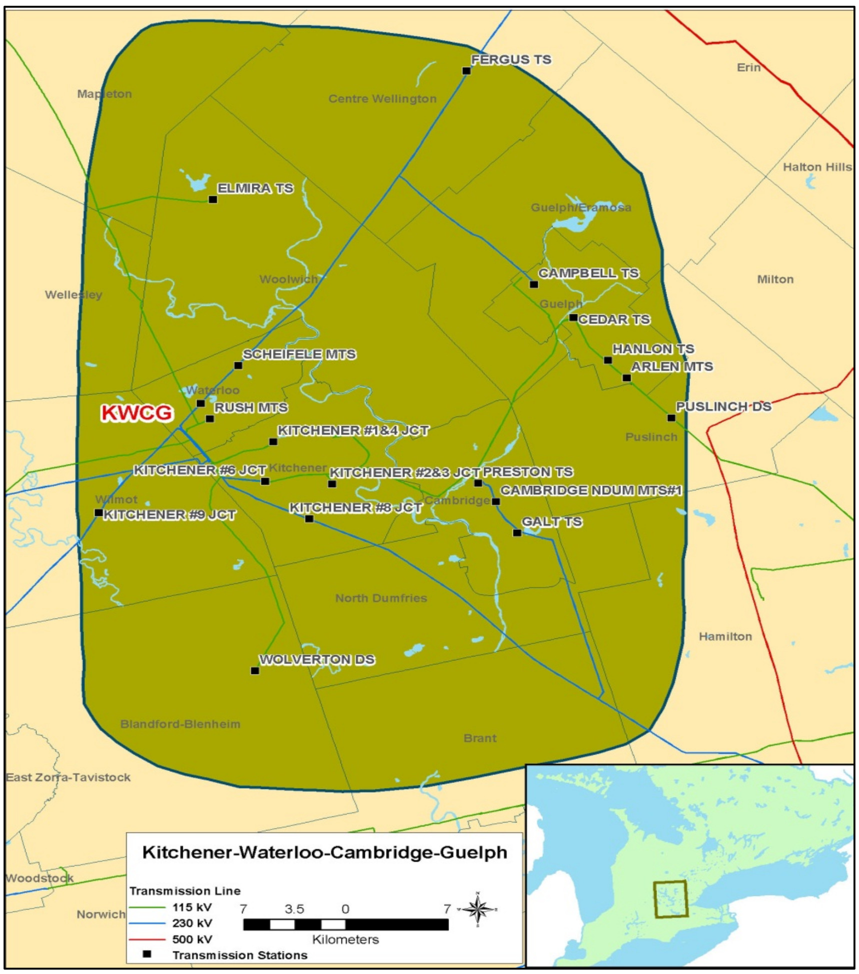

Figure 1-1 KWCG Region

The KWCG Region covers the cities of Kitchener, Waterloo, Cambridge and Guelph, portions of Oxford and Wellington counties and the townships of North Dumfries, Puslinch, Woolwich, Wellesley and Wilmot. Electrical supply to the Region is provided from eleven 230 kV and thirteen 115 kV step-down transformer stations. The summer 2015 coincident regional load was about 1240 MW. The boundaries of the Region are shown in Figure 1-1 above.

1.1 Scope and Objectives

This RIP report examines the needs in the KWCG Region. Its objectives are:

- To identify new supply needs that may have emerged since previous planning phases (e.g. Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan)
- To assess and develop a wires plan to address these needs
- To provide the status of wires planning currently underway or completed for specific needs
- To identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as load forecast, transmission and distribution system capabilities along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of all the needs and relevant plans to address near and mid-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan)
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated RIP phase information
- Develop a plan to address any longer term needs identified by the Working Group

The IRRP or RIP Working Group did not identify any long term needs at this time. If required, further assessment will be undertaken in the next planning cycle because adequate time is available to plan for required facilities.

1.2 Structure

The rest of the report is organized as the follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the region
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs
- Section 7 summarizes the Regional Plan to address the needs
- Section 8 provides the conclusions and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013, through amendments to the Transmission System Code ("TSC") and the Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ('SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation ("DG")) options at a higher or more macro level but sufficient to permit a comparison of options. If the IRRP process identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend the preferred wires solution. Similarly, resource options which the IRRP identifies as best

[1] Also referred to a Needs Screening

suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timeliness provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect
- The NA, SA, and LP phases of regional planning
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region

Figure 2-1 illustrates the various steps of the regional planning process (NA, SA, IRRP and RIP) and their respective phase trigger, lead, and outcome.

Note that as the KWCG Region was identified as a "transitional" region at the onset of the OEB defined Regional Planning process in 2013, the Needs Assessment and Scoping Assessment phases were deemed complete and the region was placed into the IRRP phase of the process.

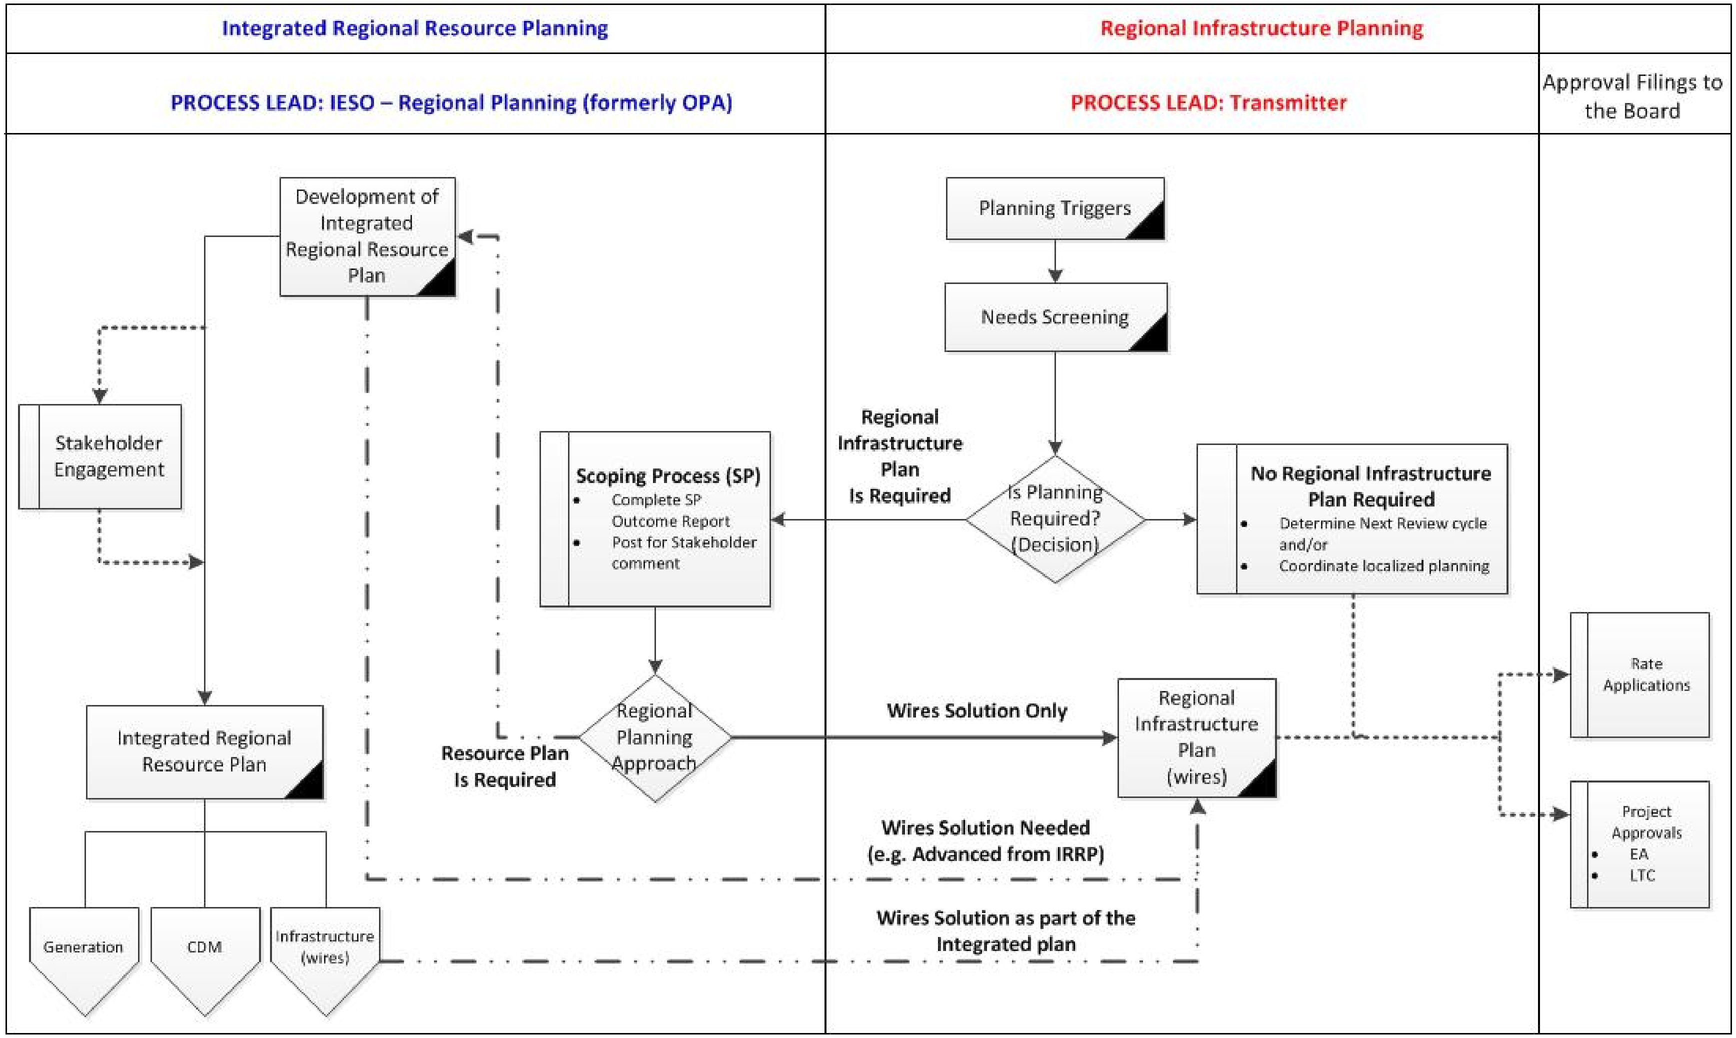

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1) Data Gathering: The first step of the RIP phase is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

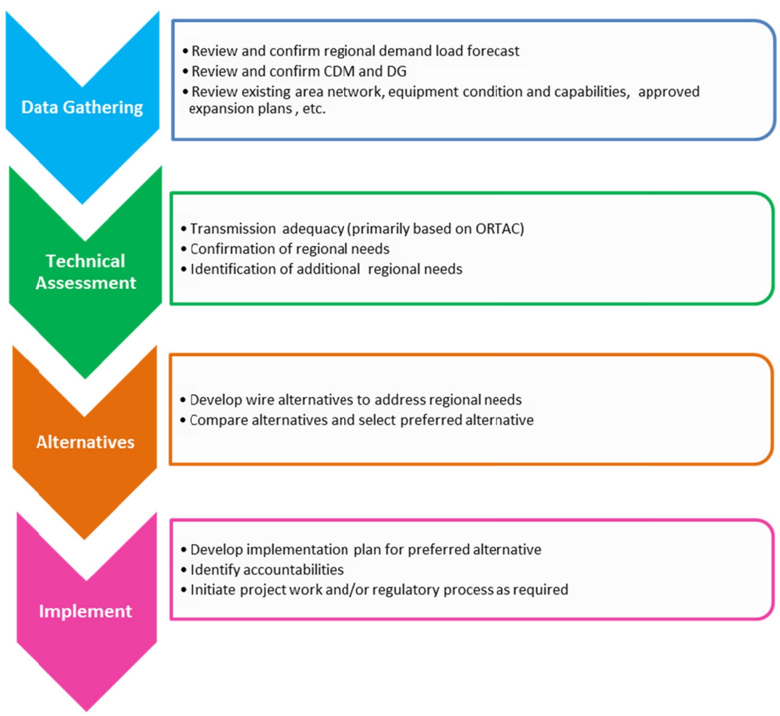

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE KWCG REGION COMPRISES OF THE CITIES OF KITCHENER, WATERLOO, CAMBRIDGE AND GUELPH, PORTIONS OF OXFORD AND WELLINGTON COUNTIES AND THE TOWNSHIPS OF NORTH DUMFRIES, PUSLINCH, WOOLWICH, WELLESLEY AND WILMOT AS SHOWN IN FIGURE 3-1.

The main sources of electricity into the KWCG Region are from four Hydro One stations: Middleport TS, Detweiler TS, Orangeville TS and Burlington TS. At these stations electricity is transformed from 500 kV and 230 kV to 230 kV and 115 kV, respectively. Electricity is then delivered to the end users of LDCs and directly-connected industrial customers by 24 step-down transformer stations. Figure 3-2 illustrates these stations as well as the four major regional sub-systems: Waterloo-Guelph 230 kV sub-system, Cambridge-Kitchener 230 kV sub-system, Kitchener-Guelph 115 kV sub-system and South-Central Guelph 115 kV sub-system. Appendix A lists all step-down transformer stations in the KWCG Region, Appendix B lists all transmission circuits in the KWCG Region and Appendix C lists LDCs in the KWCG Region.

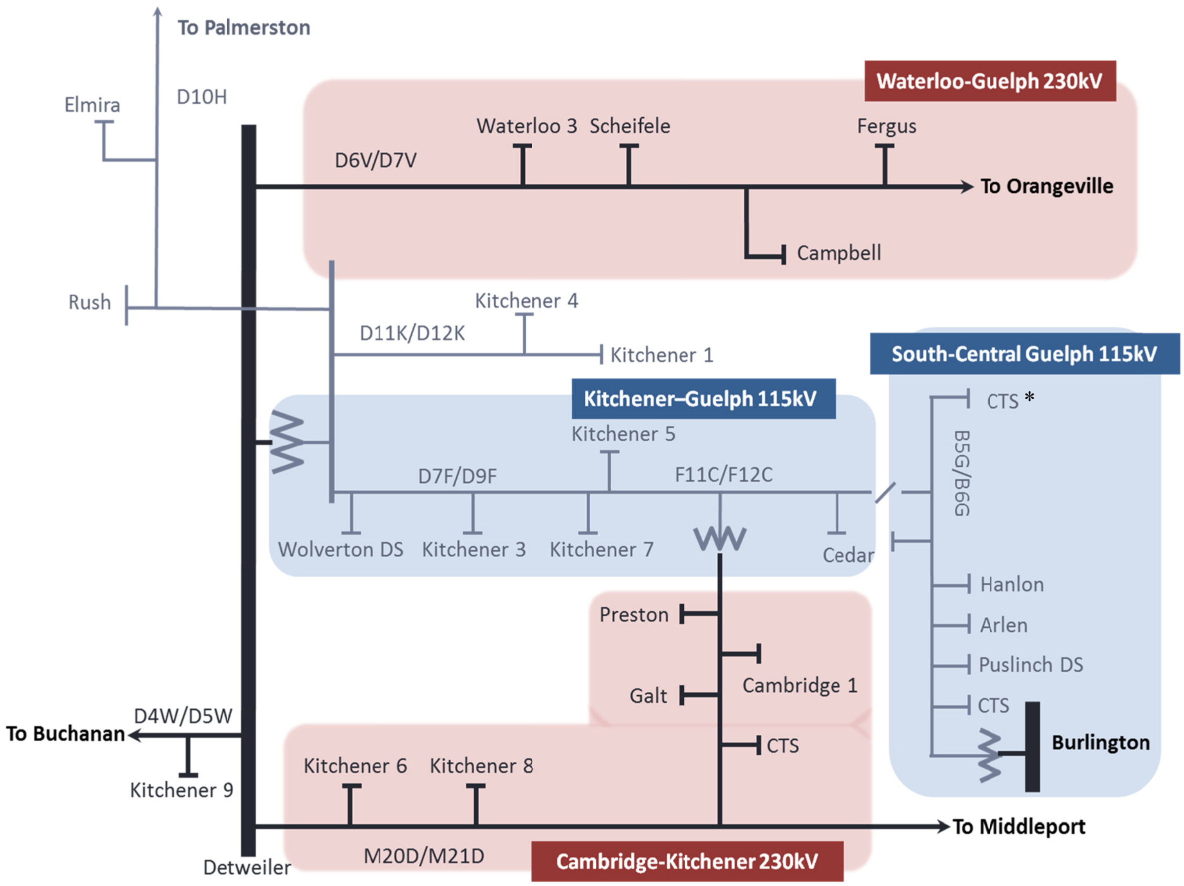

Figure 3-2 KWCG Single Line Diagram

*CTS relocated to the distribution system as part of the GATR project

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE KWCG REGION.

These projects were identified as a result of joint planning studies undertaken by Hydro One, IESO and the LDCs; or initiated to meet the needs of the LDCs; and/or to meet Provincial Government policies. A brief listing of the completed projects is given below.

For transmission voltage level transformation capacity needs:

- 250 MVA 230/115 kV autotransformer T4 at Burlington TS replaced in 2006
- 250 MVA 230/115 kV autotransformer T6 at Burlington TS replaced in 2009

For distribution voltage level transformation capacity needs:

- Kitchener MTS#9 connected to replace the Detweiler TS DESN in 2010
- Arlen MTS connected in 2011

For reactive and voltage support needs:

- a 13.8 kV shunt capacitor bank installed at Cedar TS in 2006
- a 230 kV shunt capacitor bank installed at Detweiler TS in 2007
- a 230 kV shunt capacitor bank installed at Orangeville TS in 2008
- a 230 kV shunt capacitor bank installed at Burlington TS in 2010
- a 115 kV shunt capacitor bank installed at Detweiler TS in 2012

For transmission circuit capacity needs:

- M20D/M21D circuit sections capacity increased by sag limit mitigation in 2014

For transmission load security needs:

- Freeport SS installed to sectionalize circuits D7G/D9G (Detweiler TS by Cedar TS) in 2008

For transmission load restoration needs:

- 250 MVA 230/115 kV autotransformer T2 installed at Preston TS in 2007

The following projects are underway:

- Guelph Area Transmission Reinforcement (GATR) project that entails the extension the 230kV circuits D6V/D7V to Cedar TS; the installation of two new 250MVA, 230/115kV autotransformers at Cedar TS; and the installation of two 230 kV in-line switches onto circuits D6V/D7V at Guelph North Junction. This project reinforces the Kitchener-Guelph and South-Central Guelph 115kV sub-systems as well as improves restoration capability to the Waterloo-Guelph 230 kV sub-system. This project is identified in the IESO KWCG IRRP, reference [1].

- The installation of a 13.8 kV series reactor to mitigate short circuit levels at Arlen MTS. This project was identified in the RIP phase.

- The installation two new 230kV in-line switches onto circuits M20D/M21D near Galt Junction to improve restoration capability in the Cambridge-Kitchener 230 kV sub-system. This project is identified in Hydro One's KWCG Adequacy of Transmission Facilities & Transmission Plan 2016-2025 report, reference [2]/Appendix F as well as reference [1].

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the KWCG Region is forecast to increase at an average rate of approximately 1.7% annually between 2015 and 2025. The growth rate varies across the Region with most of the growth concentrated in the cities of Waterloo and Guelph, each at an average rate of 2.5% over the next ten years.

Figure 5-1 shows the KWCG Region's planning load forecast (summer net, regional-coincident extreme weather peak). The regional-coincident (at the same time) forecast represents the total peak load of the 24 step-down transformer stations in the KWCG Region. By 2025 the forecasted coincident regional peak load is approximately 1765 MW.

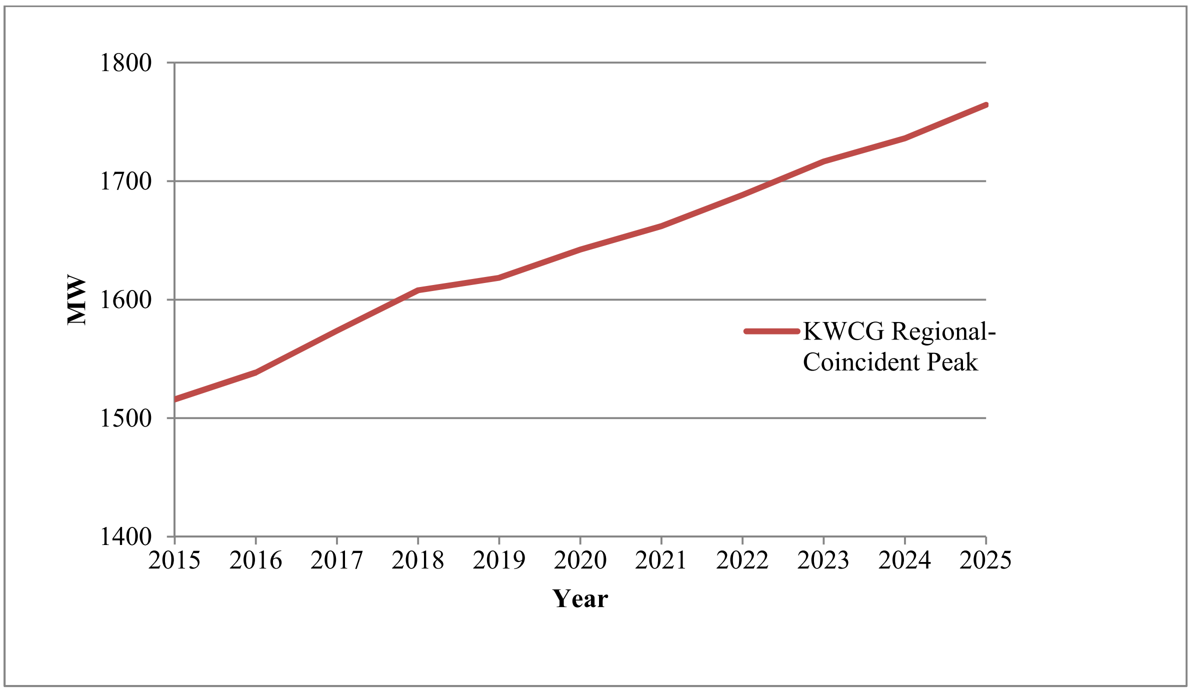

Figure 5-1 KWCG Region's Planning Forecast

The KWCG 2015 RIP planning load forecast is provided in Appendix D and is based upon the KWCG IRRP planning load forecast prepared by the IESO and was reaffirmed by the Working Group upon initiation of the RIP phase. In the IRRP phase, the LDC's provided the IESO with a 10 year gross, normal weather, regional-coincident, peak load forecast in MW. The IESO adjusted the forecast by subtracting the effective CDM capacity, applying an extreme weather factor and then subtracting the effective DG capacity. Further details regarding the CDM and connected DG are provided in reference [1]. The RIP forecast is identical to the IRRP forecast except as otherwise noted in Appendix D.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

1) The Study period for the RIP assessment is 2015-2025.
2) All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
3) Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
4) Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
5) Normal planning supply capacity for Hydro One transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR), while some LDCs use different methodologies for determining transformer station LTR.
6) Adequacy assessment is done as per the Ontario Resource and Transmission Adequacy Criteria ("ORTAC").

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2015-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND DELIVERY STATION FACILITIES SUPPLYING THE KWCG REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM.

Within the current regional planning cycle two regional assessments have been conducted for the KWCG Region. The findings of these studies are input to the RIP. The studies are:

1) IESO's KWCG Integrated Regional Resource Plan – dated April 28, 2015[1]
2) Hydro One's Adequacy of Transmission Facilities and Transmission Plan 2016-2025 – dated April 1, 2015 with revision 1 – dated October 30, 2015[2] (please see Appendix F)

The IRRP identified a number of regional needs to meet the forecast load demand over the near to mid-term. Due to the immediate nature of the needs the Guelph Area Transmission Reinforcement (GATR) project was initiated to provide adequate load supply capability to the KWCG area while the IRRP study was still underway. A detailed description and status of the GATR project and other work initiated or planned to meet these needs is given in Section 7.

This RIP reviewed the loading on transmission lines and stations in the KWCG Region assuming the GATR project is in-service. Sections 6.1-6.4 present the results of this review and Table 6-1 lists the Region's needs identified in both the IRRP and RIP phases.

Table 6-1 Near and Medium Term Regional Needs

Type	Section	Needs	Timing
Needs Identified in the IRRP [1] and the Adequacy Report [2]			
Transmission Circuit Capacity	7.1.1	South-Central Guelph 115 kV sub-system- Capacity of 115kV circuits B5G/B6G	Immediate
	7.1.2	Kitchener–Guelph 115 kV sub-system – Capacity of 115kV circuits D7F/D9F and F11C/F12C	Immediate
Load Restoration	7.1.3	Waterloo-Guelph 230 kV sub-system	Immediate
	7.2.1	Cambridge-Kitchener 230 kV sub-system	Immediate
Step-down Transformation Capacity	7.3.1	Waterloo North Hydro Inc.	2018
Additional Needs identified in RIP Phase			
Station Short Circuit Capability	7.4.1	Arlen MTS: Short Circuit capability	2016

6.1 230 kV Transmission Facilities

All 230 kV transmission circuits in the KWCG Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of the Ontario's transmission system and are also part of the transmission path from generation in Southwestern Ontario to the load centers in the Hamilton, Niagara and GTA areas. These circuits also serve local area stations within the Region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (refer to Figure 3-2):

1) Detweiler TS to Orangeville TS 230 kV transmission circuits D6V/D7V – supplies Fergus TS, Campbell TS, Waterloo North MTS#3 and Scheifele MTS
2) Detweiler TS to Middleport TS 230 kV transmission circuits M20D/M21D – supplies Kitchener MTS #6, Kitchener MTS # 8, Cambridge MTS #1, Galt TS, Preston TS and Customer #1 CTS
3) Detweiler TS to Buchanan TS 230 kV transmission circuits D4W/D5W – supplies Kitchener MTS#9.

The RIP review shows that based on current forecast station loadings and bulk transfers, all 230 kV circuits are expected to be adequate over the study period. Refer to section 3.4.2 of Appendix F for the detailed analysis.

6.2 500/230 kV and 230/115 kV Transformation Facilities

Bulk power supply to the KWCG Region is provided by Hydro One's 500 kV to 230 kV and 230 kV to 115 kV autotransformers. The number and location of these autotransformers are as follows:

1) Two 500/230 kV autotransformers at Middleport TS
2) Four 230/115 kV autotransformers at Burlington TS
3) Three 230/115 kV autotransformers at Detweiler TS
4) Two 230/115 kV autotransformers at Cedar TS
5) One 230/115 kV autotransformer at Preston TS

The RIP review shows that based on current forecast station loadings and bulk transfers, the auto-transformation supply capacity is adequate over the study period. Refer to section 3.4.1 of Appendix F for the detailed analysis.

6.3 Supply Capacity of the 115 kV Network

The KWCG Region contains five pairs of double circuit 115 kV lines. This 115 kV network serves local area load. These circuits are as follows (see Figure 3-2):

1) Detweiler TS to Freeport SS 115 kV transmission circuits D7F/D9F – supplies Wolverton DS, Kitchener MTS #3, Kitchener MTS#7
2) Freeport SS to Cedar TS 115 kV transmission circuits F11C/F12C – supplies Kitchener MTS#5 and Cedar T1/T2 transformers
3) Burlington TS to Cedar TS 115 kV transmission circuits B5G/B6G – supplies Puslinch DS, Arlen MTS, Hanlon TS, Customer #2 CTS and Cedar T7/T8 transformers
4) Detweiler TS 115 kV radial transmission circuit D11K/D12K – supplies Kitchener MTS#1 and Kitchener MTS#4
5) Detweiler TS to Seaforth TS/Hanover TS 115 kV transmission circuit D8S/D10H with Normally Open (N/O) points – supplies Rush MTS and Elmira TS

The RIP review shows that based on current forecast station loadings and bulk transfers, the supply capacity of the 115 kV network is adequate over the study period. Refer to section 3.4.3 of Appendix F for the detailed analysis.

6.4 Step-down Transformer Stations

There are 24 step-down transformer stations within the KWCG Region. Twenty-two supply electricity to LDCs and two are transmission-connected industrial customer stations. These stations are listed within the load forecast in Appendix D. Of those 24 stations, 15 of them are owned and operated by the LDCs.

As part of the IRRP, step-down transformation station capacity was reviewed and resulted in the IRRP forecast which was reaffirmed by the Working Group for use in the RIP phase. According to the load forecast, Waterloo North Hydro anticipates requiring additional step-down transformation capacity in 2018.

6.5 Other Items Identified During Regional Planning

6.5.1 Customer Impact Assessment for the GATR project

Based on the Customer Impact Assessment [3] for the GATR project, Guelph Hydro identified the need to mitigate short circuit levels at Arlen MTS in order to ensure the short circuit levels remain within the TSC limits and equipment ratings. The project need date is May 2016 so as to correlate with the completion of the GATR project.

6.5.2 System Impact Assessment for the GATR Project

A System Impact Assessment ("SIA") [4] was performed for Hydro One's application to the IESO for the Guelph Area Transmission Reinforcement (GATR) project.

Several findings emanated from the SIA report due to conservative assumptions made for the Bulk Power System. The Working Group has reviewed these findings and recommends that the assumptions be looked at in greater detail within a Bulk Power System study. If the Bulk Power System study results in regional needs then an early trigger of the next Regional Planning cycle may occur.

6.5.3 Load Restoration to the Cambridge area

The IRRP recommended Hydro One to continue to explore options with Cambridge and North Dumfries Hydro ("CND") to further improve the load restoration capability to the Cambridge area. During the RIP phase Hydro One presented to CND a detailed explanation of its capability to restore power to transformer stations that service the Cambridge area. Based on this discussion, CND and Hydro One have agreed that, at this time, no additional infrastructure is required and the restoration capability afforded by the GATR project and the 230 kV in-line switches at Galt Junction is acceptable for the study period.

6.6 Long-Term Regional Needs

The IRRP examined high-growth and low-growth scenarios to identify long-term needs. Under the high-growth scenario, there is sufficient transmission capacity afforded by the GATR project to meet demand in the long-term; however the need for additional step-down transformation capacity may arise. LDC's to closely monitor their load to determine the timing of potential step-down transformation needs. Under the low-growth scenario, no needs were identified in the long-term.

Consistent with the IRRP, the Working Group did not identify any additional long-term needs during the RIP phase. If new long-term needs were to arise, there is sufficient time to assess them in the next planning cycle which can also be started earlier to make timely investment decisions..

7. REGIONAL PLANS

THIS SECTION DISCUSSES THE ELECTRICAL SUPPLY NEEDS FOR THE KWCG REGION AND SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THE NEEDS. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE IRRP AS WELL AS THE NEEDS IDENTIFIED DURING THE RIP PHASE.

7.1 Transmission Circuit Capacity and Load Restoration

7.1.1 South-Central Guelph 115 kV Sub-system

The South-Central Guelph area is supplied by the 115 kV double circuit line B5G/B6G. As per section 6.2.1 of the IRRP, historical peak demand on the B5G/B6G line has already exceeded the 100 MW line Load Meeting Capability ("LMC").

7.1.2 Kitchener-Guelph 115 kV Sub-system

The Kitchener-Guelph area is supplied by two 115 kV double-circuit lines D7F/D9F and F11C/F12C supported by 230/115 kV autotransformers at Detweiler TS and Preston TS. As per section 6.2.1 of the IRRP, the planning forecast peak demand in the Kitchener-Guelph 115 kV sub-system will exceeded the 260 MW line LMC by summer 2014.

7.1.3 Waterloo-Guelph 230 kV Sub-system

As per section 6.2.2 of the IRRP, the transmission infrastructure supplying load in the Waterloo-Guelph 230 kV sub-system does not meet reliability requirements to quickly restore supply in the event of a major outage involving the loss of both transmission circuits, D6V and D7V.

7.1.4 Recommended Plan and Current Status

To address the transmission circuit capacity needs for the South-Central Guelph 115 kV sub-system and the Kitchener-Guelph 115 kV sub-system, the IRRP Working Group recommended reinforcement of the 115 kV transmission system by introducing a new 230 kV – 115 kV injection point. The new injection point is to be located at Cedar TS using two new 230 kV/115 kV autotransformers in conjunction with a 5 km extension of the existing 230 kV double-circuit transmission line, D6V/D7V from Campbell TS to Cedar TS. This reinforcement is covered under the GATR project.

To address the load restoration need of the Waterloo-Guelph 230 kV sub-system, the IRRP Working Group's preferred alternative is to install two new 230 kV in-line switches near Guelph North Junction. The switches will enable Hydro One to quickly isolate a problem and allow the resupply of load to occur expeditiously. This work is also covered under the GATR project.

Current Status of the GATR Project

Hydro One initiated construction on the GATR project in fall 2013 following the OEB approval in September 2013. The project has three components:

- Campbell TS x Cedar TS: Extend the 230 kV D6V/D7V tap from Campbell TS to Cedar TS. This requires replacing approximately a 5 km section of the existing 115 kV double circuit transmission section between CGE Junction and Campbell TS with a new 230 kV double circuit transmission line,
- Cedar TS: Install two new 230/115 kV autotransformers and associated 115 kV switching facilities at Cedar TS. Connect 115 kV switching facilities to the existing B5G/B6G line and the F11C/F12C at Cedar TS.
- Guelph North Junction: Install two in-line 230 kV switches at Guelph North Jct.

This investment will provide for sufficient 230/115 kV autotransformation capacity beyond the study period. The current in-service date of the project is May 2016.

The cost of this project is approximately $95 million. The project is a transmission pool investment as the autotransformers provide supply to all customers in the Region.

7.2 Load Restoration

7.2.1 Cambridge-Kitchener 230 kV Sub-system

As per section 6.2.2 of the IRRP and the section 3.4.8 of the Adequacy of Transmission Facilities report, transmission infrastructure supplying load in the Cambridge-Kitchener 230 kV sub-system does not meet reliability requirements to quickly restore supply in the event of a major outage involving the loss of both transmission circuits, M20D and M21D.

7.2.2 Recommended Plan and Current Status

To address the load restoration need of the Cambridge-Kitchener 230 kV sub-system, the IRRP Working Group's preferred alternative is to install two new 230 kV in-line switches on the M20D/M21D line near Galt Junction. The switches will enable Hydro One to quickly isolate a problem and allow the resupply of load to occur expeditiously. This work is covered under the M20D/M21D Install 230 kV In-line Switches project.

Current Status of the 230 kV In-Line Switches near Galt Junction

Hydro One has established a project to install the two 230 kV in-line switches onto the M20D/M21D double circuit line. One set of switches to be installed onto each circuit. One set of switches to be installed north of the Junction while the other to be installed south of Galt Junction. The switches will enable

Hydro One to quickly isolate a problem on either side of the junction and initiate the restoration of load to the Cambridge-Kitchener 230 kV sub-system.

The project is currently in the detailed design and estimation phase which also includes real estate negotiations. The cost of this project is approximately $6 million and it will be a transmission pool investment. The planned in-service date is May 2017.

7.3 Step-down Transformation Capacity

7.3.1 Waterloo North Hydro

The RIP/IRRP planning load forecast indicates that additional step-down transformation capacity is required by 2018, specifically Waterloo North Hydro's MTS #4.

7.3.2 Recommended Plan and Current Status

To address step-down transformation capacity needs of Waterloo North Hydro, Waterloo North Hydro will, wherever possible, manage load growth by maximizing the utilization of existing stations by increasing distribution load transfer capability between those stations and will continue to explore opportunities for CDM and DG. In addition Waterloo North Hydro will also explore, with other LDCs, opportunities to coordinate possible joint use and development of step-down transformer stations in the Region over the long term. With this in mind, additional step-down transformation capacity is not anticipated prior to 2024. This need will be reviewed in the next cycle of regional planning.

7.4 Station Short Circuit Capability

7.4.1 Arlen MTS

Arlen MTS is a 115/13.8 kV step-down transformer station owned by Guelph Hydro. As a result of the new 230/115 kV injection point afforded by the GATR project, the short circuit levels at Arlen MTS's 13.8 kV bus will exceed the TSC limit and equipment capability.

7.4.2 Recommended Plan and Current Status

To address the station short circuit capability need at Arlen MTS, Guelph Hydro will install series reactors to bring station short circuit levels within TSC limits and within equipment ratings.

Current Status of Short Circuit Mitigation

Guelph Hydro has initiated a project to install series reactors to bring station short circuit levels within TSC limits and equipment ratings. The cost of this project is $0.95 million and the expected completion date is May 2016 so as to correlate with the completion of the GATR project.

8. CONCLUSIONS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE KWCG REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

Six near and mid-term needs were identified for the KWCG Region. They are:

I. Transmission capacity in the South-Central Guelph 115 kV sub-system
II. Transmission capacity in the Kitchener-Guelph 115 kV sub-system
III. Load restoration capability in the Waterloo-Guelph 230 kV sub-system
IV. Load restoration capability in the Cambridge-Kitchener 230 kV sub-system
V. Step-down transformation capacity for Waterloo North Hydro
VI. Station Short Circuit Capacity at Arlen MTS

This RIP report addresses all six of these needs. Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the near and mid-term needs are summarized in the Table 8-1 below.

Table 8-1 Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

No.	Project	Next Steps	Lead Responsibility	I/S Date	Cost	Needs Mitigated
1	Guelph Area Transmission Reinforcement	Construction in the final stages	Hydro One	May 2016	$95M	I, II, III
2	Mitigate Short Circuit Levels at Arlen MTS	Construction underway	Guelph Hydro	May 2016	$0.95M	VI
3	M20D/M21D – Install 230 kV In-line Switches	Transmitter to carry out this work	Hydro One	May 2017	$6M	IV
4	Waterloo North Hydro: MTS #4	LDC to monitor growth	Waterloo North Hydro	2024	TBD	V

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Customer #2 CTS	Customer Station (Assumed Values)	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0

Table D1 -is based upon KWCG 2015 IRRP Planning Load Forecast except as noted.

(1) Cambridge and North Dumfries Hydro ("CND") has confirmed 9.2 MW of cogeneration at a large customer to be accounted for in the Preston TS forecast starting year 2016. The generation plant is expected to run most of the time and would offset the customer's load. This cogeneration was not factored into the KWCG 2015 IRRP Planning Load Forecast.

(2) Both CND and Waterloo North Hydro ("WNH") are monitoring the load closely to determine the timing of potential transformation needs. For planning purposes, WNH has moved back the in service date of MTS #4 from 2018 to 2024. WNH is closely monitoring the need for additional transformation capacity to determine if the load growth indicated at MTS #4 in the forecast can be managed through a combination of improving transformer station interties, CDM and DG in the Waterloo Region. Where possible, these LDCs are exploring opportunities to coordinate possible joint use and development of step-down transformer station facilities in the KWCG Region over the long term.

(3) Updated to include Hydro One Distribution load

(4) Based on information provided by the transmission-connected customer

Appendix F. KWCG Adequacy of Transmission Facilities and Transmission Plan 2016-2025

Revision 1

KITCHENER/WATERLOO/CAMBRIDGE/GUELPH AREA

ADEQUACY OF TRANSMISSION FACILITIES

AND

TRANSMISSION PLAN 2016 – 2025

October 30, 2015

Prepared by Hydro One Networks Inc. in Consultation with the KWCG Working Group

Foreword

This report is the result of a joint study by KWCG Working Group. It has been prepared by Hydro One Networks in consultation with the Working Group.

The working group members were:

Entity	**Member**
Kitchener-Wilmot Hydro	Shaun Wang L. Frank G. Cameron
Waterloo North Hydro Inc.	Herbert Haller David Wilkinson Dorothy Moryc
Cambridge & North Dumfries Hydro	Ron Sinclair Shawn Jackson
Guelph Hydro Electric System Inc.	Michael Wittemund K. Marouf Eric Veneman
Hydro One Distribution	Charlie Lee
Ontario Power Authority	Bob Chow Bernice Chan
Independent Electricity Operator	Peter Drury
Hydro One Networks Inc.	Alessia Dawes Farooq Qureshy Emeka Okongwu Qasim Raza

The preferred plan has been selected based on technical and economic considerations. The issue of cost allocation between utilities was not addressed.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

In 2010 an integrated regional planning study was initiated to assess the electricity supply and reliability over a twenty year period for the Kitchener-Waterloo-Cambridge-Guelph (KWCG) areas and continues to be conducted by a Working Group led by the Ontario Power Authority (OPA) and includes staff from the Independent Electricity System Operator (IESO), Hydro One Networks Inc., Kitchener-Wilmot Hydro, Waterloo North Hydro, Cambridge & North Dumfries Hydro, Guelph Hydro Electric Systems Inc. and Hydro One Distribution.

The early results of the integrated regional planning study identified the need to reinforce supply capacity for the South-Central Guelph and the City of Cambridge over the near and medium term. It also identified the need to minimize the impact of double circuit interruptions in the area[1]. As a result, the Working Group recommended two transmission projects in conjunction with conservation and distributed generation:

1. The Guelph Area Transmission Reinforcement (GATR) project – comprising a new 230/115kV autotransformer station at Guelph Cedar TS, upgrading the circuit section between Campbell TS and CGE Junction to 230 kV and in-line switching on the Orangeville TS x Detweiler TS 230kV circuits D6V/D7V – to reinforce supply to South Central Guelph,
2. The Preston TS Autotransformer Project – comprising the installation of a second 230/115kV autotransformer at Preston TS - to reinforce supply to the City of Cambridge.

Work on the GATR project was started in 2014 following approval from the Ontario Energy Board and the Ministry of Environment. The project's planned in-service date is June 2016.

For the Preston project, the OPA issued Hydro One a hand off letter to develop a "Wires" solution to improve the supply to the Cambridge area and to facilitate the connection of a future Cambridge and North Dumfries Hydro transformer station by 2018.

This report presents the results of Hydro One led "Wires" study of the adequacy of supply to the City of Cambridge and the wider KWCG area based on the planned in-service of the GATR project in summer 2016. The main conclusions of the report are as follows:

- The supply capability to the KWCG 115kV area has been significantly increased to meet all 2025 forecast loads by the addition of the GATR project. The need for the Preston autotransformer can be deferred to beyond 2025.
- There is inadequate load restoration capability for load connected to Middleport TS x Detweiler TS 230kV double circuit line M20D and M21D

This report recommends that the most cost effective plan to improve load restoration capability for load connected to circuits M20/21D is to install 230 kV in-line switches onto circuits M20/21D.

[1] OPA Submission to the OEB for the GATR Project – Document EB-2013-0053 dated March 8, 2013 entitled, "Kitchener-Waterloo-Cambridge-Guelph Area

1.0 INTRODUCTION

This transmission adequacy assessment focused on the electrical supply to the municipalities of Kitchener, Waterloo, Cambridge and Guelph and their surrounding areas of Ontario, collectively referred to as the KWCG area in this report. Its primary focus was to confirm the near and mid-term transmission needs for the area and to provide a 10-year transmission plan in order satisfy those Needs.

Geographically, the KWCG area consists of 4 municipalities – Kitchener, Waterloo, Cambridge, Guelph and portions of two counties - Perth and Wellington. Hydro One Networks Inc. is the sole high voltage transmitter in the KWCG area; however the low voltage distribution of electricity in the KWCG area is carried out by Cambridge and North Dumfries Hydro Inc., Guelph Hydro Electric System Inc., Hydro One Distribution, Kitchener-Wilmot Hydro Inc., and Waterloo North Hydro. A geographic map of the area is shown in Appendix A, Map 1 while an electrical map of the area is shown in Appendix A, Map 2.

The KWCG area is a major regional load centre in Ontario. The area has a well-established history in manufacturing and technology. The area peak load is approximately 1400 MW.

This report presents the results of the Hydro One led “Wires” study of the adequacy of supply to the City of Cambridge and the wider KWCG area based on the planned in-service of the GATR project in summer 2016.

2.0 EXISTING TRANSMISSION INFRASTRUCTURE

2.1 TRANSMISSION IN KWCG

Electrical Supply in this area is provided through 230 kV and 115 kV transmission lines and step down transformation facilities (transmission stations, TS) as show in Appendix A, Map 2.

The main sources of electricity into the KWCG Region are Middleport TS, Detweiler TS, Orangeville TS, Cedar TS and Burlington TS. At these stations electricity is transformed from 500 kV and 230 kV to 230 kV and 115 kV, respectively. The KWCG Region transmission system is connected as follows:

- Two 230 kV circuits (D6V/D7V) that run North-East from Detweiler TS to Orangeville TS that supply five load serving stations;
- Two 230 kV circuits (M20/21D) that run South-East from Detweiler TS to Middleport TS that supply five load serving stations and one transmission-connected customer;
- Two 230 kV circuits (D4W/D5W) that run South-West from Detweiler TS to Buchanan TS (in the “London area”) that supply one load serving station;
- Four 115 kV circuits (D7F/D9F, F11C/F12C) that run East-West: D7/9F from Detweiler TS to Freeport SS that supply three load serving stations and F11/12C from Freeport SS to Cedar TS that supply one load serving station;
- Two 115 kV circuits (B5G/B6G) that run North-West from Burlington TS to Cedar TS that supply three load serving stations and one transmission-connect customer;
- Two 115 kV radial circuits (D11K/D12K) emanating East from Detweiler TS that supply two load serving stations; and,
- Two 115 kV circuit (D8S and D10H) emanating North from Detweiler TS that supply two load serving stations in the KWCG area.

Voltage support is provided in the area by:

- Four high voltage shunt capacitor banks and one SVC at Detweiler TS
- Four high voltage shunt capacitor banks at Middleport TS
- Three high voltage shunt capacitor banks at Burlington TS
- One high voltage shunt capacitor bank at Orangeville TS
- 43.2 MVar low voltage station shunt capacitor at Galt TS
- 21.6 MVar low voltage station shunt capacitors at Campbell TS
- 59.81 MVar low voltage station shunt capacitors at Cedar TS
- 9.92 MVar low voltage station shunt capacitors at Elmira TS
- Low voltage feeder shunt capacitors were lumped at: C&ND MTS#1, Waterloo North Hydro MTS #3, Scheifele MTS

All stations in the KWCG Region were considered in the analysis to determine the adequacy of the existing transmission system. Transformation capacity at individual load serving stations was previously analyzed by the OPA as part of the Integrated Regional Resource Plan (IRRP). The result of that analysis was a load forecast that included proposed new stations, as shown in Appendix C. Therefore, transformation capacity at individual load serving stations was not considered in this study.

2.2 TRANSMISSION-CONNECTED GENERATION

There are no existing large-scale transmission-connected generation plants in the KWCG area; however two contracted renewable transmission-connected wind farms were included in the study area and are listed in Appendix B.

3.0 ADEQUACY OF EXISTING TRANSMISSION INFRASTRUCTURE IN KWCG AREA

3.1 STUDY ASSUMPTIONS

Assumptions were made in order to assess the effects of contingencies to verify the adequacy of the transmission system. The assumptions used in the study were:

1. A 10 year load forecast: years 2016 to 2025; shown in Appendix C
2. Forecasted loads were provided by the LDC's in MW. The MVAR portion of the load was set to 40% of the MW load which is a reasonable assumption to achieve a power factor of 0.9 at the defined meter point of load serving transformer stations (TS, CTS, MTS)
3. A summer assessment was performed as the KWCG area is summer load peaking while the equipment is at its lowest rating during summer ambient conditions. This was deemed to be the most conservative approach;
4. Equipment continuous and Limited Time Ratings (LTR) were based on an ambient temperature of 35°C for summer and a wind speed of 4 km/hour;
5. The Guelph Area Transmission Reinforcement (GATR) project would be in-service in June 2016;
6. Circuits M20D and M21D are assigned their updated long-term emergency rating (LTE) based on a maximum temperature of 127°C;
7. Simulation of year 2025 load forecast was performed as it was the maximum loading of the area for the duration of the study period; year 2016 was simulated as necessary;
8. Waterloo North Hydro's Snider MTS #4 (MTS #4) will connect to 230 kV circuit D6/7V between Scheifele MTS and Guelph North Jct., projected in-service date 2024 (refer to Note 2 in Appendix C, Table C1)
9. The flows on Ontario's major internal transmission interfaces were assumed as follows:
   - FETT ~ 4500 MW
   - FS ~1250 MW
   - FABCW ~ 5800MW
   - NBLIP ~ 1650 MW (the slightly high NBLIP was offset by the lower FABCW)
   - QFW ~ 1550 MW

3.2 STUDY CRITERIA

The adequacy of the transmission system is assessed as per the IESO Ontario Resource and Transmission Assessment Criteria, Issue 5.0.

3.3 LOAD FORECAST

The load forecast used in this assessment is the KWCG 2015 RIP forecast as shown in Appendix C. This summer forecast is an extreme weather, area coincident, net, peak load forecast.

The KWCG 2015 RIP forecast is based upon the KWCG 2015 IRRP forecast. The LDC's provided the IESO with a 20 year gross, normal weather, area coincident, peak load forecast in MW. The IESO adjusted the forecast by subtracting the effective conservation and demand management (CDM) capacity, applying an extreme weather factor and then subtracting the effective Distribution Generation (DG) capacity.

3.4 SUPPLY CAPACITY NEEDS

Single element contingencies were considered in assessing the adequacy and reliability of the local transmission system that serves the KWCG area. Figure 1 summarizes the local KWCG area Needs for the 10-year period under study. Appendices D, F and G detail the technical study and results.

At stations, within the KWCG area, classified as NPCC Bulk Power System (BPS) additional contingencies were considered to establish their impact to the local KWCG area. Appendix E details the technical study and results.

3.4.1 AUTO-TRANSFORMATION SUPPLY CAPACITY

There is no major generation station in the KWCG area. Hence, the majority of supply to the load is provided by Hydro One's 500 kV to 230 kV and 230 kV to 115 kV auto-transformers. The number and location of these auto-transformers are as follows:

- Two 500/230 kV autotransformers at Middleport TS
- Four 230/115 kV autotransformers at Burlington TS[2]
- Three 230/115 kV autotransformers at Detweiler TS
- Two 230/115 kV autotransformers at Cedar TS
- One 230/115 kV autotransformer at Preston TS

Single autotransformer contingencies were performed to assess the adequacy of the transmission system to supply bulk power into the KWCG area via the autotransformers for year 2025 loading.

The results indicate that there are no thermal overloads and no voltage violations for the loss of a single autotransformer.

[2] The loading of the autotransformers at Burlington TS is mainly driven by the load connected in the Burlington to Nanticoke area. Only a small percentage of the autotransformer load is due to local Guelph load and as such, analysis of the Burlington TS autotransformers was undertaken in the 'Burlington to Nanticoke' Regional Infrastructure Plan.

3.4.2 Supply Capacity of the 230 kV Network

The KWCG area contains three pairs of double circuit 230 kV lines: M20D/M21D, D6V/D7V and D4W/D5W.

Single circuit contingencies were performed to assess the adequacy of the local 230 kV transmission system for year 2025 loading[3].

As indicated in Appendix D there are no thermal overloads and no voltage violations for the loss of a single 230 kV circuit.

3.4.3 Supply Capacity of the 115 kV Network

The KWCG area contains five pairs of double circuit 115 kV lines: D7F/D9F, F11C/F12C, B5G/B6G, D11K/D12K and D8S/D10H.

Single circuit contingencies were performed to assess the adequacy of the local 115 kV transmission system for year 2025 loading.

As indicated in Appendix D there are no thermal overloads and no voltage violations for the loss of a single 115 kV circuit. Appendix H details supply capacity on circuit D8S and D10H as request by the LDC.

3.4.4 Voltage Performance

Single circuit contingencies as well as single element HV shunt capacitor bank contingencies were performed to determine the overall voltage performance of the KWCG area for year 2025 loading.

As indicated in Appendix D there are no thermal overloads and no voltage violations for these contingencies. Appendix H details voltage performance at Elmira TS and Rush MTS as request by the LDC.

3.4.5 Load Security Analysis

The most stringent load security criterion that applies to the KWCG area states that with any two elements out of service:

- Voltage must be within applicable emergency ratings and equipment loading must be within applicable short-term emergency ratings;
- Load transfers to meet the applicable long-term emergency ratings must be able to be made in the time afforded by short-time ratings;
- Planned load curtailment or load rejection in excess of 150 MW is not permissible (except for local generation outages) and;

[3] Note, if another element such as an autotransformer, circuit or capacitor bank shared the same “switching position” and/or zone of protection with the circuit under contingency, both were removed from service.

- Not more than 600 MW of load may be interrupted by configuration and by planned load curtailment or load rejection excluding voluntary demand management with any two transmission elements out of service.

There are three pairs of 230 kV double circuit lines and five pairs of 115 kV double circuit lines in the KWCG area. While one circuit of a double circuit line is out of service, the loss of the companion circuit in the pair would result in the loss of all load stations connected to the pair by configuration. Tables F1 and F2 in Appendix F illustrate the load lost due to configuration in both years 2016 and 2025.

There are five stations in the KWCG area that have autotransformers. Overlapping autotransformer contingencies were taken and Table F3 in Appendix F illustrates any load transfer requirements due to two overlapping autotransformer outages.

As seen in Appendix F, the load forecasted on all circuit pairs is less than 600 MW within the 10-year study period and the loss of two autotransformers within this local area does not result in equipment loading beyond their applicable emergency ratings; therefore there is no concern with Load Security in the KWCG area for the study period.

3.4.6 Load Restoration Capability Analysis

The load restoration criteria requires that the transmission system be planned such that following local area design criteria contingencies, the affected loads can be restored within the restoration times indicated below[4]:

- All load lost must be restored within 8 hours;
- Load lost in excess of 250 MW must be restored within 30 min; and
- Load lost between the amount of 150 MW and 250 MW must be restored within 4 hours.

Each pair of double circuit 230 kV and 115 kV lines were assessed to verify their load restoration capability. This assessment is detailed in Appendix G.

The results indicated the existing transmission system can adequately restore load to each circuit pair with the exception of M20/21D. Therefore, improvement to the restoration capability of load connected to circuits M20D and M21D is required.

3.4.7 Impact of Contingencies on the BPS to the KWCG Area

Northeast Power Coordinating Council (NPCC) Bulk Power System stations in the KWCG area are:

- Middleport TS 500 kV bus
- Middleport TS 230 kV bus
- Detweiler TS 230 kV bus

[4] As per ORTAC: “These approximate restoration times are intended for locations that are near staffed centres. In more remote locations, restoration times should be commensurate with travel times and accessibility.”

All elements connected to BPS buses are considered BPS facilities. Elements refer to circuit breakers, transmission lines, generators, transformers and reactive devices (e.g. SVC or capacitor bank).

Appendix E: Technical Results-Bulk Power System Considerations provides a list of BPS contingencies and the results. A *limited* number of BPS contingencies were performed in order to establish the impact of contingencies on the BPS to the local KWCG area.

Three NPCC Directory 1 contingency events were utilized in this study:

1. Simultaneous loss of two adjacent transmission circuits on a multiple circuit tower
2. Loss of any element with delayed fault clearing (a.k.a. Breaker Failure)
3. Loss of a critical element, followed by system adjustment, then loss of a critical element.

These BPS contingency events were applied to BPS buses only. The results can be summarized as follows:

- As per Table E3 and E5 when two of the three auto-transformers at Detweiler TS are not available the remaining auto-transformer may become overloaded. Since the loading of the remaining auto-transformer is within its 15-minute Short-Term Emergency Rating (STE) operational control actions can be taken to reduce the loading to within acceptable limits. Control actions could entail isolation of the faulted element e.g. circuit breaker, bus or transformer, and placing back in-service a healthy auto-transformer (at Detweiler TS and/or Preston TS). Another control action could entail opening of 115kV breakers at Freeport SS to redirect flows through the Cedar TS autotransformers.

3.4.8 Summary of Needs

Figure 1 illustrates the Needs timeline for the KWCG region.

Figure 1: Transmission Needs in the KWCG Area

4.0 Options to Address the Need

Options were considered to address the insufficient load restoration capability for loads connected to circuits M20D and M21D. These options are shown in Table 1. Although there are several metrics that can be utilized to measure and compare options, the simple metric "initial capital cost/MW of load restored" was selected because it compares the unit costs of remedial measures. This was deemed sufficient in order to select the preferred option

Table 1: Options to Improve M20/21D Load Restoration

Option	Options to Improve Restoration	Fault on the Main Line – Restorable Load (Note 1)	Fault on the Tap – Restorable Load (Note 1)	Initial Capital Cost (Note 3)	Initial Capital Cost/ MW Load Restored
--	Existing (Benchmark)	100 MW (Preston TS only)	100 MW (Preston TS only)	0	$0/MW
1	230 kV in-line switches on M20/21D at **Preston Junction**	100 MW (C&ND load only-Note 2)	100 MW (C&ND load only-Note 2)	$6M	$60k/MW
2	230 kV in-line switches on M20/21D at **Galt Junction** (main line)	368 MW - 484 MW	234 MW (100 MW via existing Preston Auto)	$6M	$12k/MW to $26k/MW
3	One 230 kV cap bank at Preston TS plus 230 kV in-line switches on MxD at **Preston Junction**	140 MW (Note 4) (C&ND load only-Note 2)	140 MW (Note 4) (C&ND load only-Note 2)	$11M	$79k/MW
4	2nd autotransformer at Preston TS plus 230 kV in-line switches on MxD at **Preston Junction**	200 MW (Note 4) (C&ND load only-Note 2)	200 MW (Note 4) (C&ND load only-Note 2)	$21M	$105k/MW
5	2nd autotransformer at Preston TS plus 230 kV in-line switches on MxD at **Preston Junction** plus two 230 kV cap banks at Preston TS	280 MW (Note 4) (C&ND load only-Note 2)	280 MW (Note 4) (C&ND load only-Note 2)	$31M	$111k/MW

NOTE 1 Restorable load values are approximate values only as the actual amount of restorable load will depend on the prevailing system conditions and Operating/Control Centre protocols and priorities

NOTE 2 "C&ND load only" means that only those customers connected to Galt TS, C&ND MTS#1 and Preston TS will benefit. Cambridge and North Dumfries Hydro customers are the sole customers of these three stations.

NOTE 3 All prices are based on historical data: taxes extra, overhead extra, no escalation considered, no assumptions are made to feasibility or constructability, no assumptions made as to space requirements, real estate and environmental cost extra

NOTE 4 Restoration of 230 kV load (Cambridge and North Dumfries load) via the Preston TS auto-transformer may require operational measures on the 115 kV system to secure the transmission system to handle a subsequent contingency e.g. open the low voltage bus-tie breakers/switches at 115kV connected stations

5.0 DISCUSSION OF PREFERRED OPTIONS

5.1 PREFERRED OPTION TO IMPROVE RESTORATION TO M20/21D LOAD

Currently, loads connected to circuits M20/21D do not meet the restoration criteria.

Of the five options, option #2: 230 kV in-line switches on M20/21D at/near Galt Junction is the preferred option to satisfy the Need as it will provide the capability to restore the most load supplied from M20/21D.

Not only does Option #2 allow for more load to be restored, it provides for better operational flexibility; and is the most economical solution. As option 2 substantially meets the need by significantly improving the existing restoration capability, it is therefore the preferred option.

6.0 DEVELOPMENT PLAN

The transmission infrastructure development plan for the KWCG area is as followings:

1) <u>Immediate Action: Install 230 kV In-Line Switches</u>

Install 230 kV Load Interrupter type in-line switches on circuits M20D and M21D on the main line near Galt Junction. Note that load interrupter type switches cannot be used to interrupt fault current.

7.0 CONCLUSIONS

The following conclusions can be reached from the analysis performed by this study.

<u>Local Area Performance</u>

1. Improvement to the load restoration capability of transmission-connected customers on circuits M20D and M21D is required. The preferred option can be implemented by summer 2017.

<u>BPS Performance</u>

2. Autotransformer T2 at Detweiler TS is expected to be at 104.4% of LTE loading for year 2016 for the following contingency:
    i. Detweiler T4 outage plus Detweiler T3 with M20D (includes Preston T2 via Preston SPS). Since the post-contingency flow is below the auto-transformer STE, operational control actions can be taken to reduce loading to within the LTE rating.

8.0 RECOMMENDATIONS

The following recommendations are to address the transmission infrastructure deficiencies within the study period for the KWCG area. These recommendations are:

1. Hydro One Networks to install a set of 230 kV in-line switches onto the main line of circuits M20D and M21D near Galt Junction as soon as possible.
2. Hydro One Networks, the LDCs and the IESO to review the KWCG local area in 2019 with updated KWCG load forecasts to decide on appropriate actions to meet longer-term needs as they emerge.

APPENDIX A: KWCG MAPS

Planning demand (MW) = ((Gross-CDM) x Extreme Weather Factor) – DG

*Based upon KWCG 2015 IRRP Planning Load Forecast except where otherwise noted.

Note 1: The LDC has confirmed 9.2 MW of cogeneration at a large customer to be accounted for in the Preston TS forecast starting year 2016. The generation plant is expect to run most of the time and would offset the customer's load. This cogeneration was not factored into the KWCG 2015 IRRP Planning Load Forecast.

Note 2: The LDC has confirmed that additional transformation capacity (Snider/Bradley TS) would not be required until after 2024. The exact location and timing of these TS's have not been determined at this time. The load growth indicated at Snider and Bradley in the forecast can be managed by existing TS's/impact of CDM/DG in the Waterloo Region. LDCs are monitoring the load closely to determine the timing of potential transformation needs. Where possible, these LDCs are exploring opportunities to coordinate use and development of TS facilities in the KWCG Region over the long term. Cambridge #2 is assumed to be supplied off the KWCG 115kV system

Note 3: Slight modification from KWCG 2015 IRRP Planning forecast based on information provided by the transmission-connected customer

Note: Guelph CTS 1 forecast was removed as the LDC confirmed the load was already accounted for within their forecast

APPENDIX D: TECHNICAL RESULTS – LOCAL AREA ANALYSIS

Single element contingencies were considered in order to determine the presence of thermal overload and/or voltage violations.

Table D1: Single Element Contingencies (single zone of protection)

Loss of a Single Circuit (N-1)					
D11K	D12K	D8S	D10H	D7F	D9F

Results: Thermal Overload and Voltage Violations

Table D3: Thermal Analysis (>100% LTE), year 2025

Element	Contingency	%LTE
All circuits and auto-transfers are within ratings		

Table D4: Voltage Analysis, year 2025

Element	Contingency	%Voltage Decline	Voltage kV
All voltages are within criteria			

APPENDIX E: TECHNICAL RESULTS – BULK POWER SYSTEM CONSIDERATIONS

Applicable contingencies were considered on BPS elements to establish their impact on the local area.

Table E1: N-2 Contingencies

Loss of a Double Circuit Line (N-2) emanating from a BPS station		
B22D and B23D	D4W and D5W	M20D and M21D
D6V and D7V	--	--
Breaker Failure (B/F) Contingencies at BPS station (N-2)		
Detweiler TS 230 kV bus	B/F of AL6	Loss of: D6V, Cedar T3, Detw T4, M21D, Preston T2
	B/F of AL7	Loss of: D7V, Cedar T4, M21D, Preston T2
	B/F of L7L20	Loss of: D7V, Cedar T4, M20D, Detw T3, Preston T2
	B/F of HT1A	Loss of: M21D, Preston T2, SVC1
	B/F of ACS21	Loss of : M21D, Preston T2, SC21
	B/F of HL20	Loss of: M20D, Detw T3, D5W, SC22
	B/F of T2SC21	Loss of: Detw T2, SC21
	B/F of HT2	Loss of: Detw T2, SC21, D5W
	B/F of DL22	Loss of: B22D, D6V, Cedar T3, Detw T4
Middleport TS 500 kV bus	Covered under Loss of Middleport T3 and T6 autotransformers for the local area analysis (Appendix D)	
Middleport TS 230 kV bus	There are no B/F conditions that would be critical to the supply to the KWCG area.	

Table E2: N-1-1 Contingencies

Loss of a Critical Element, System Adjustment, Loss of a Critical Element (N-1-1)
Loss of: Detw T4 plus Detw T3 (plus M20D by configuration which also includes the loss of Preston T2 via Preston SPS)
Loss of: Preston T2 plus D7V (plus Cedar T4 by configuration)

Note that during the simulations no System Adjustment was afforded; this is considered a conservative approach.

Results: Thermal Overloads and Voltage Violations

As per Table E3 and E5: Detweiler TS 230/115 kV autotransformer T2 will become overloads when Detweiler TS autotransformer T4 is out-of-service followed by the loss of Detweiler TS autotransformer T3 in conjunction with circuit M20D by configuration. Preston TS autotransformer T2 is also removed from service via the Preston SPS.

Table E3: Thermal Analysis (>95% LTE), year 2016

Element	Contingency	%LTE
Detweiler TS T2 autotransformer	Detweiler T4 plus Detweiler T3 with M20D (includes Preston T2 via Preston SPS)	104.4 (74.2% STE*) %

*STE rating of Detweiler T2 auto-transformer is 396 MVA.

Table E4: Voltage Analysis, year 2016

Element	Contingency	%Voltage Decline	Voltage kV
All voltages are within criteria			

Table E5: Thermal Analysis (>95% LTE), year 2025

Element	Contingency	%LTE
Detweiler TS T2 autotransformer	Detweiler T4 plus Detweiler T3 with M20D (includes Preston T2 via Preston SPS)	114.2 (81.4%STE*)

*STE rating of Detweiler T2 auto-transformer is 396 MVA.

Table E6 Voltage Analysis, year 2025

Element	Contingency	%Voltage Decline	Voltage kV
All voltages are within criteria			

APPENDIX F: LOAD SECURITY ANALYSIS

Load connected to each circuit pair that is lost by configuration following an [N-2] double circuit contingency is:

Table F1: Load Lost Due to Configuration, year 2016

Circuit Pair	MW
M20/21D	420
D6/7V	482
D4/5W	34
D7/9F	131
F11/12C	74
B5/6G	105
D11/12K	98
D8S/D10H	89

Table F2: Load Lost Due to Configuration, year 2025

Circuit Pair	MW
M20/21D	489
D6/7V	571
D4/5W	36
D7/9F	141
F11/12C	78
B5/6G	128
D11/12K	103
D8S/D10H	95[6]

Table F1 illustrates that none of the double circuit contingencies result in more than 482 MW of load lost in year 2016.

Table F2 illustrates that none of the double circuit contingencies result in more than 571 MW of load lost in year 2025.

[6] D8S and D10H emanate out of Detweiler TS as a double circuit line however after ~ 5 km they each become a single circuit 115 kV line. Based on their N/O open points, the loss of the double circuit line within the 5 km span out of Detweiler TS, will results in approximately 95 MW of load lost.

Table F3: Two Elements Out of Service

Loss of a Double Circuit Line		
D7F and D9F	F11C and F12C	B5G and B6G
D4W and D5W	M20D and M21D	D11K and D12K
D6V and D6V		

Loss of Two Autotransformers[7]				
Station	**Detweiler Auto**	**Preston Auto**	**Cedar Auto**	**Burlington Auto**
Detweiler Auto	N/A	Detweiler T3 + Preston T2	Cedar T3 + Detweiler T4	Burlington T6 + Detweiler T3
Preston Auto	Detweiler T3 + Preston T2	N/A	Cedar T4 + Preston T2	Burlington T6 + Preston T2
Cedar Auto	Cedar T3 + Detweiler T4	Cedar T4 + Preston T2	Cedar T3 + Cedar T4	Burlington T6 + Cedar T3
Burlington Auto	Burlington T6 + Detweiler T3	Burlington T6 + Preston T2	Burlington T6 + Cedar T3	N/A

Results: Thermal Overload and Voltage Violations

Table F5: Thermal Analysis (>100% STE), year 2025

Element	Contingency	%STE
All circuits and auto-transfers are within ratings		
Element	**Contingency**	**%LTE**
All circuits and auto-transfers are within ratings		

Table F6: Voltage Analysis (> emergency ratings), year 2025

Element	Contingency	%Voltage Decline	Voltage kV
All voltages are within criteria			

[7] For stations that have three or more autotransformers connected in parallel typical operating practice after the loss of one autotransformer is to make load transfers to other interconnected autotransformer station(s) such that the remaining load at the affected station would be at or below the station's reduced Limited Time Rating (LTR). It is assumed the in this case that sufficient time between single autotransformer contingencies is available for such load transfers to be carried out by operator response.

APPENDIX G: LOAD RESTORATION ANALYSIS

Restoration of Load Connected to M20/21D

By year 2025 the total forecasted load connected to circuits M20/21D is 489 MW. Loss of this double circuit line would result in the loss of all 489 MW. In order to restore load to these stations at least one circuit would have to be placed back in service**,** noting that to restore Customer #1 CTS circuit M21D must specifically be placed back in service due to the customer's single-circuit transmission-connection

Based on criteria:

Load Required to be Restored	Duration
239MW	30 min.
100 MW	Within 4 hrs.
150 MW	Within 8 hrs.

Existing infrastructure allows for only the restoration of 100 MW of load in approximately 30 min. This can be accomplished by opening the M20/211D line disconnect switches at Preston TS and back-feed Preston TS T2 230-115 kV autotransformer to supply load at Preston TS only.

Therefore, the existing restoration capability to loads connected to M20/21D does not meet criteria for the duration of the study period.

Restoration of Load Connected to D6/7V

By year 2025 the total forecasted load connected to D6/7V is 571 MW. Loss of this double circuit line would result in the loss of all 571 MW. As part of the Guelph Area Transmission Reinforcement project, two 230 kV in-line switches will be installed in year 2016 on the main line between Detweiler TS and Orangeville TS at Guelph North Junction. To restore load to these stations, the operator will utilize these switches to isolate the problem and return to service the remaining healthy circuit sections. These switches allow for more flexibility to restore load to the affected stations in a timely fashion.

Based on criteria:

Load Required to be Restored	Duration
321MW	30 min.
100 MW	Within 4 hrs.
150 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and

3. the relative distance from the nearest field maintenance centre[8]

the load restoration criterion is substantially met. Therefore, no additional transmission restoration capability is warranted at this time.

<u>Restoration of Load Connected to D4/5W</u>

By year 2025 the total forecasted load connected to D4/5W is 36 MW. Loss of this double circuit line would result in the loss of all 36 MW. To restore load to this station at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
36 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

<u>Restoration of Load Connected to D7/9F</u>

By year 2025 the total forecasted load connected to D7/9F is 141 MW. Loss of this double circuit line would result in the loss of all 141 MW. To restore load to these stations at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
141 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

[8] The KWCG area is considered an urban area and as such, access to transmission facilities, repair materials and personnel in order to make a repair within 8 hours is realistic. A Hydro One field maintenance centre is located in Guelph.

Restoration of Load Connected to F11/12C

By year 2025 the total forecasted load connected to F11/12C is 78 MW. Loss of this double circuit line would result in the loss of all 78 MW. To restore load to these stations at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
78 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to B5/6G

By year 2025 the total forecasted load connected to B5/6G is 128 MW. Loss of this double circuit line would result in the loss of all 128 MW. To restore load to Enbridge Westover CTS's circuit B5G must be placed back in service due to the CTS's single-circuit transmission connection. To restore load at the other stations at least one circuit would to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
128 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to D11/12K

The total forecasted load serviced by radial circuits D11/12K will not exceed 103 MW by 2025. Loss of this double circuit line would result in the loss of all 103 MW. To restore load to these stations at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
103 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to D8S/D10H

The total forecasted load serviced by these radially operated 115 kV circuits will not exceed approximately 95 MW by year 2025. Loss of this double circuit line would result in loss of all 95MW. To restore Rush MTS either circuit can be placed back into service or the station could possibly be fed via circuit L7S out of Seaforth TS; however to restore Elmira TS circuit D10H must be placed back in service due to Elmira TS's single-circuit transmission-connection.

Based on criteria:

Load Required to be Restored	Duration
95 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

APPENDIX H: SUPPLY TO ELMIRA TS AND RUSH MTS

Study Results:

Table H1: Station Capacity: Summer Ratings and Summer Load Forecast

Station	Transformer Capacity (10-day LTR)	Year 2025 Load Forecast
Rush MTS	69 MVA*	61.3 MW / 69.9 MVA (0.88 pf** at defined meter point, 115 kV side)
Elmira TS	58.5 MVA	33.6 MW / 37.1 MVA*** (0.91 pf at defined meter point, 115 kV side)

*The limiting component is a low voltage cable; when required the limiting component will be modified and the rating to be 75 MVA

** Power factor at the defined meter point improves to 0.92 when 5.4 MVar of installed feeder capacitor banks assumed lumped at the LV bus and results in 66.8 MVA loading

*** A 9.2 MVar @ 27.6 kV shunt capacitor bank is installed at Elmira TS not in-service; when in-service power factor improves and loading through the transformers decrease.

Table H2: Transmission Capacity of circuits D8S and D10H

Year	Contingency	D10H – Detweiler TS x Waterloo Jct.	D8S – Detweiler TS x Leong Jct.
		590 A Continuous *640 A Long-Term Emergency (LTE)* *660 A Short-Term Emergency (15-min.)*	*590 A Continuous* *640 A Long-Term Emergency (LTE)* *660 A Short-Term Emergency (15-min.)*
2016	Pre	287 A	285 A
	Loss of D8S	454 A	--
	Loss of D10H	--	459 A
2025	Pre	319 A /	302 A
	Loss of D8S	511	--
	Loss of D10H	--	500 A

-assume all St. Mary's TS load is supplied by D8S (as this is more conservative for the study), assume Conestogo Wind Farm not-service (as it would displace load on D10H) and the normally-open point on D10H is between Elmira TS and Palmerston TS

Table H3: Voltage Profile at Rush MTS and Elmira TS

Year	**Contingency**	**Rush MTS 115 kV D8S**	**Rush MTS 115 kV D10H**	**Rush MTS 13.8 kV**	**Elmira TS 115 kV**	**Elmira TS 27.6 kV**
2016	Pre	122.2	122.2	14.4	120.8	27.2
	Loss of D8S	--	121.8	13.7	120.6	27.1
	Loss of D10H	121.5	--	13.7	--	--
2025	Pre	123.2	123.1	14.2	121.6	27.3
	Loss of D8S	--	122.6	13.6	121.1	27.2
	Loss of D10H	122.4	--	13.6	--	--

-assume all St. Mary's TS load is supplied by D8S (as this is more conservative for the study), assume Conestogo Wind Farm not-service (as it would displace load on D10H) and the normally-open point on D10H is between Elmira TS and Palmerston TS

Analysis:

D8S

Circuit D8S has a normally open point at St. Mary's TS separating the circuit from circuit L7S. D8S normally supplies half the load at Rush MTS and half the load at St. Mary's TS. The other half of the load at Rush MTS is normally supplied by circuit D10H and the other half of the load at St. Mary's TS is normally supplied by L7S. Referring to Table H2, for the loss of circuit D10H, circuit D8S has sufficient capacity to supply all load at Rush MTS and St. Mary's TS for year 2025 and beyond.

D10H

Circuit D10H runs between Detweiler TS and Hanover TS and has a normally open point between Elmira TS and Palmerston TS. Elmira TS is normally supplied from Detweiler TS while Palmerston TS is normally supplied from Hanover TS. Referring to Table H2, D10H has sufficient capacity to supply all load at Elmira TS for year 2025 and beyond. When circuit D8S is out of service, D10H has sufficient capacity to supply all load at Elmira TS and Rush MTS (while St. Mary's TS is supplied by circuit L7S).

Rush MTS

Since this station is a Municipal owned station, Waterloo North Hydro is to ensure there is sufficient transformation capacity to accommodate load growth. According to load forecasts and referring to Table H1, over the next 10-years load will fluctuate above and below the year 2025 forecast but will be remain within the station's Limited Time Rating (LTR). Waterloo North Hydro is to inform Hydro One if the connection requires modification and/or if a new station connection is required in order to accommodate load growth. Waterloo North Hydro has already incorporated their future Snider MTS and Bradley MTS into the KWCG regional plan to cater for load growth.

Rush MTS is supplied by two 115 kV circuits, D8S and D10H. Referring to Tables H2 and H3, when one of these circuits is out of service, the voltage profile at Rush MTS is healthy and the other circuit has sufficient capacity to supply all load to Rush MTS.

Elmira TS

According to the forecast and referring to Table H1, transformers at Elmira TS have sufficient capacity for year 2025 loading and beyond.

Elmira TS is supplied by one 115 kV circuit, D10H. Referring to Tables H2 and H3, the voltage profile at Elmira TS is healthy and the circuit has sufficient capacity to supply load to Elmira TS for year 2025 loading and beyond.

When circuit D10H out of Detweiler TS is unavailable, Elmira TS may also be supplied by D10H out of Hanover TS (by closing the normally open point between Palmerston TS and Elmira TS). Assuming Palmerston TS is at its forecasted year 2025 normal weather peak load, approximately 25 MW of load at Elmira TS may be supplied out of Hanover TS. The limiting factor being the 115 kV voltage profile on D10H as Elmira TS is nearly 80 circuit km from Hanover TS.

Metro Toronto

REGIONAL INFRASTRUCTURE PLAN

January 12, 2016

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Enersource Hydro Mississauga
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
PowerStream Inc.
Toronto Hydro-Electric System Limited
Veridian Connections Inc.

[This page is intentionally left blank]

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE WORKING GROUP IN ACCORDANCE TO THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE METRO TORONTO REGION.

The participants of the RIP Working Group included members from the following organizations:

- Enersource Hydro Mississauga
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator ("IESO")
- PowerStream Inc.
- Toronto Hydro-Electric System Limited ("THESL")
- Veridian Connections Inc.
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the regional planning process and it follows the completion of the Central Toronto Sub-Region's Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015 and the and Metro Toronto Northern Sub-Region's Needs Assessment ("NA") Study by Hydro One in June 2014.

This RIP provides a consolidated summary of needs and recommended plans for both the Central Toronto Sub-Region and Metro Toronto Northern Sub-Region that make up the Metro Toronto Region.

The Central Toronto IRRP has identified longer term needs beyond 2025. These longer term needs are also reviewed and discussed in this report. However, as the need dates are beyond 2025, adequate time is available to develop a preferred alternative in the next planning cycle expected to be started in 2018.

The major infrastructure investments planned for the Metro Toronto Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the Table below.

No.	Project	I/S date	Cost ($M)
1	Manby Autotransformer Overload Protection Scheme	2018	$2
2	Runnymede TS Expansion & Manby x Wiltshire Corridor Upgrade	2019	$90
3	Horner TS Expansion	2020	$53
4	Richview x Manby Corridor Upgrade	2020	$20-40
5	Copeland MTS Phase 2	2020+	$46

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. As mentioned above, the next planning cycle is expected to be started in 2018. However, the Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the regional planning cycle will be started earlier to address the need.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE METRO TORONTO REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") on behalf of the Working Group that consists of Hydro One, Enersource Hydro Mississauga, Hydro One Networks Inc. Distribution, the Independent Electricity System Operator ("IESO"), PowerStream Inc., Toronto Hydro-Electric System ("THESL"), and Veridian Connections Inc. in accordance with the new Regional Planning process established by the Ontario Energy Board in 2013.

The Metro Toronto Region is comprised of the City of Toronto. Electrical supply to the Region is provided by thirty five 230kV and 115kV transmission and step-down stations as shown in Figure 1-1. The eastern, northern and western parts of the Region are supplied by eighteen 230/27.6kV step-down transformer stations. The central area is supplied by two 230/115kV autotransformer stations (Leaside TS and Manby TS) and fifteen 115/13.8kV and two 115/27.6kV step-down transformer stations. The summer 2015 area load of the Metro Toronto region was about 4700MW.

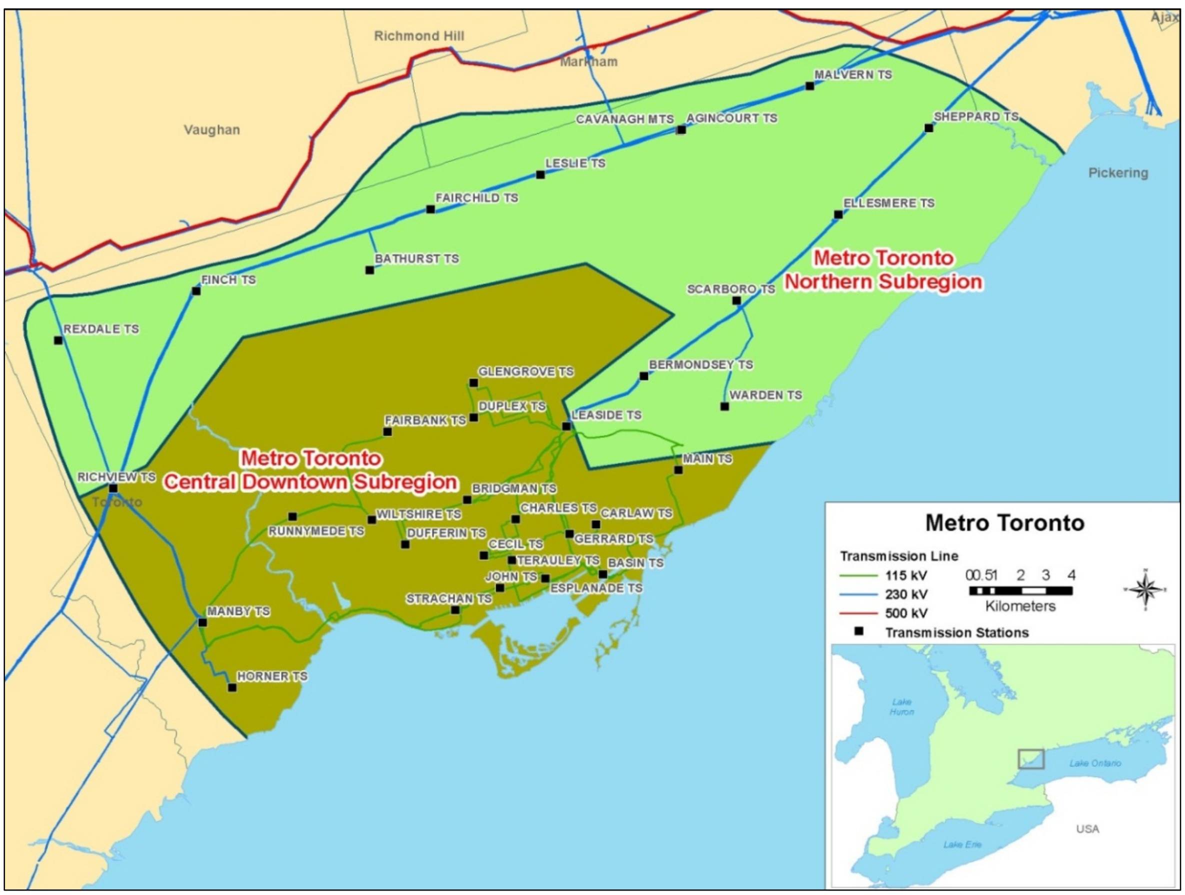

Figure 1-1 Map of Metro Toronto Region

1.1 Scope and Objectives

This RIP report examines the needs in the Metro Toronto Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plan to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated information;
- Develop a plan to address any longer term needs identified by the Working Group.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs;
- Section 7 discusses the needs and provides the alternatives and preferred solutions;
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

[1] Also referred to as Needs Screening.

a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee (LAC) in the region or sub-region. For the Metro Toronto Region, community engagement through a formal LAC is on-going.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

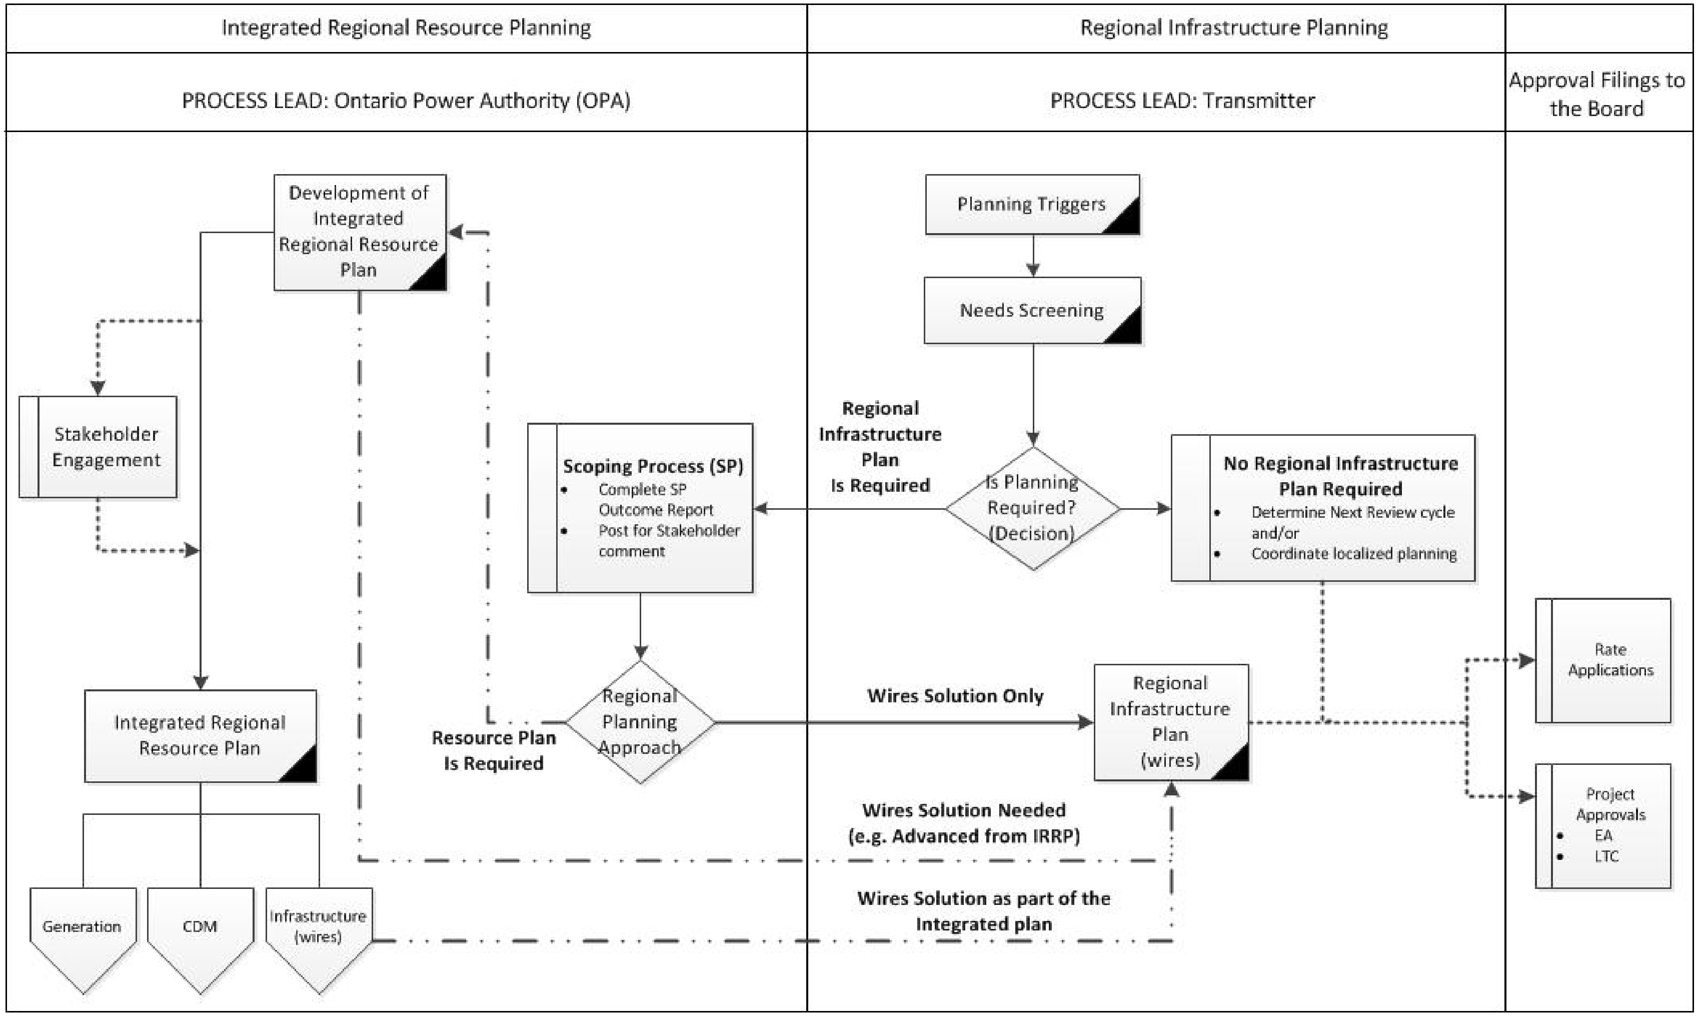

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1) Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

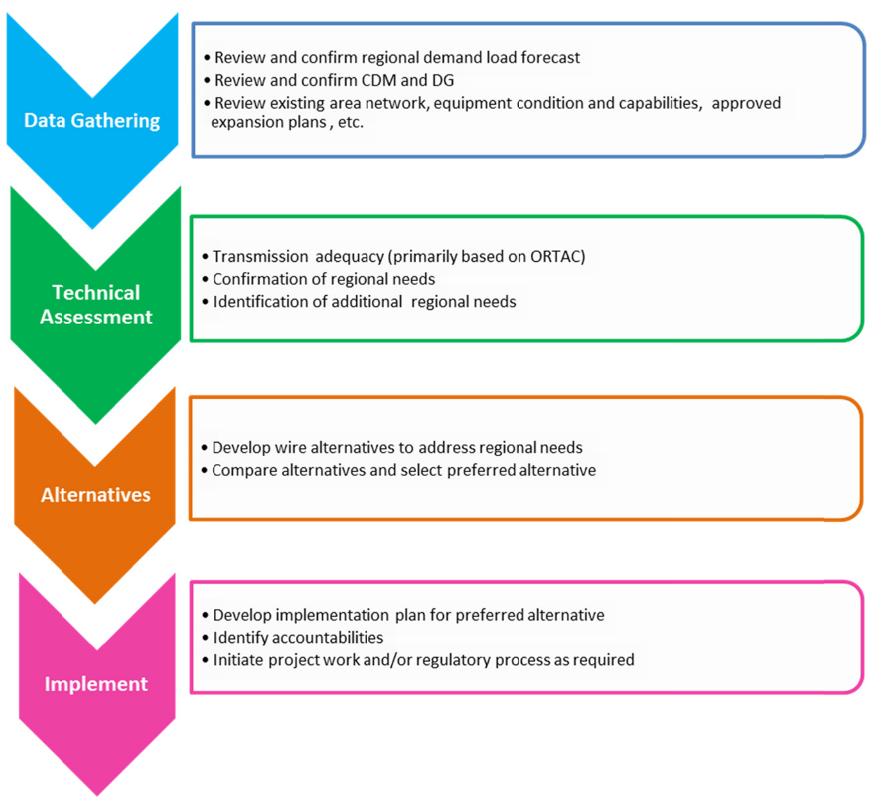

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE METRO TORONTO REGION INCLUDES THE AREA ROUGHLY BORDERED GEOGRAPHICALLY BY LAKE ONTARIO ON THE SOUTH, STEELES AVENUE ON THE NORTH, HIGHWAY 427 ON THE WEST AND REGIONAL ROAD 30 ON THE EAST. IT CONSISTS OF THE CITY OF TORONTO, WHICH IS THE LARGEST CITY IN CANADA AND THE FOURTH LARGEST IN NORTH AMERICA.

Bulk electrical supply to the Metro Toronto Region is provided through three 500/230 kV transformers stations - Claireville TS, Cherrywood TS and Parkway TS and a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. Local generation in the area consists of the 550 MW Portlands Energy Centre located near downtown area and connected to the 115 kV network at Hearn Switching Station. The Metro Toronto Region 2015 peak summer demand was about 4700MW which represents about 20% of the gross electrical demand in the province.

Toronto Hydro-Electric System Limited ("THESL") is the Local Distribution Company ("LDC") that serves the electricity demands for the city of Toronto. Other LDCs supplied from electrical facilities in the Metro Toronto Region are Hydro One Networks Inc. Distribution, PowerStream Inc., Veridian Connections Inc., and Enersource Hydro Mississauga. The LDCs receive power at the step down transformer stations and distribute it to the end users – industrial, commercial and residential customers.

The April 2015 Integrated Regional Integrated Regional Resource Plan ("IRRP") report, prepared by the IESO in conjunction with Hydro One and the LDC, focused on the Central Toronto Area which included the 115kV network and the 230kV facilities in the western part of Region. The June 2014 Metro Toronto Northern Sub-Region Needs Assessment report, prepared by Hydro One, considered the remainder of the Metro Toronto region. A map and a single line diagram showing the electrical facilities of the Metro Toronto Region, consisting of the two sub-regions, is shown in Figure 3-1 and Figure 3-2 respectively. Please note that the facilities shown include the new Leaside TS to Bridgman TS 115kV circuit L18W and the new Copeland MTS. The L18W circuit is being built as part of the Midtown Transmission Reinforcement Project and Copeland MTS is a new THESL owned transformer station to serve the downtown area. Work on these projects is in the advanced stage and both are expected to come into service in 2016.

3.1 Central Toronto Sub-Region

The Central Toronto Sub-Region includes the area extending northward from Lake Ontario to roughly Highway 401, westward to Highway 427 and Etobicoke Creek, and eastward to Victoria Park Avenue.

The Central Toronto Sub-Region was identified as a "transitional" region, as planning activities in the region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete, and the regional planning process was considered to be in the IRRP phase. An IRRP for the region was completed in April 2015.

The Central Toronto Sub-region is further subdivided into two areas:

- The Richview Manby 230kV area: This includes the former borough of Etobicoke and is served by the Richview TS to Manby TS 230kV circuits. The area has two 230/27.6kV step-down transformer stations. The coincident peak summer 2015 area load was about 320 MW. The Richview TS to Manby 230kV circuits together with the Richview TS to Cooksville TS circuit R24C supply a number of stations in the GTA West Southern Sub-Region. These stations while outside the Metro Toronto Region have therefore been included in Figure 3-2.

- The Central 115kV Area: The central area is supplied by two 230/115kV autotransformer stations (Leaside TS and Manby TS), fifteen 115/13.8kV and two 115/27.6kV step-down transformer stations. The area includes the downtown core including the financial, entertainment and educational districts. The 2015 summer coincident area load was about 1900MW.

Please see Figure 3-1 and 3-2 for a map and single line diagram of the Sub-Region facilities.

3.2 Metro Toronto Northern Sub-Region

The Metro Toronto Northern Sub-Region comprises the remainder of the Metro Toronto region. It includes the area roughly bordered geographically by Highway 401 on the south, Steeles Avenue on the north, Highway 427 on the west and Regional Road 30 on the east in addition to the area east of the Don Valley Parkway and north of O'Connor Dr.

Electrical supply to the Metro Toronto Northern Sub-Region is provided through 230 kV transmission lines and step-down transformation facilities. Supply to this sub-region is provided from a 230 kV transmission system consisting of the Richview TS to Parkway TS, the Richview TS to Cherrywood TS, the Richview TS to Claireville TS, as well as the Cherrywood TS to Leaside TS 230kV transmission system. The area is served primarily at 27.6kV by fifteen step-down transformer stations with a pocket of 13.8kV load supplied from Leaside TS and Leslie TS. The 2015 summer coincident area load was about 2500 MW.

Please see Figure 3-1 and 3-2 for a map and single line diagram of the Sub-Region facilities.

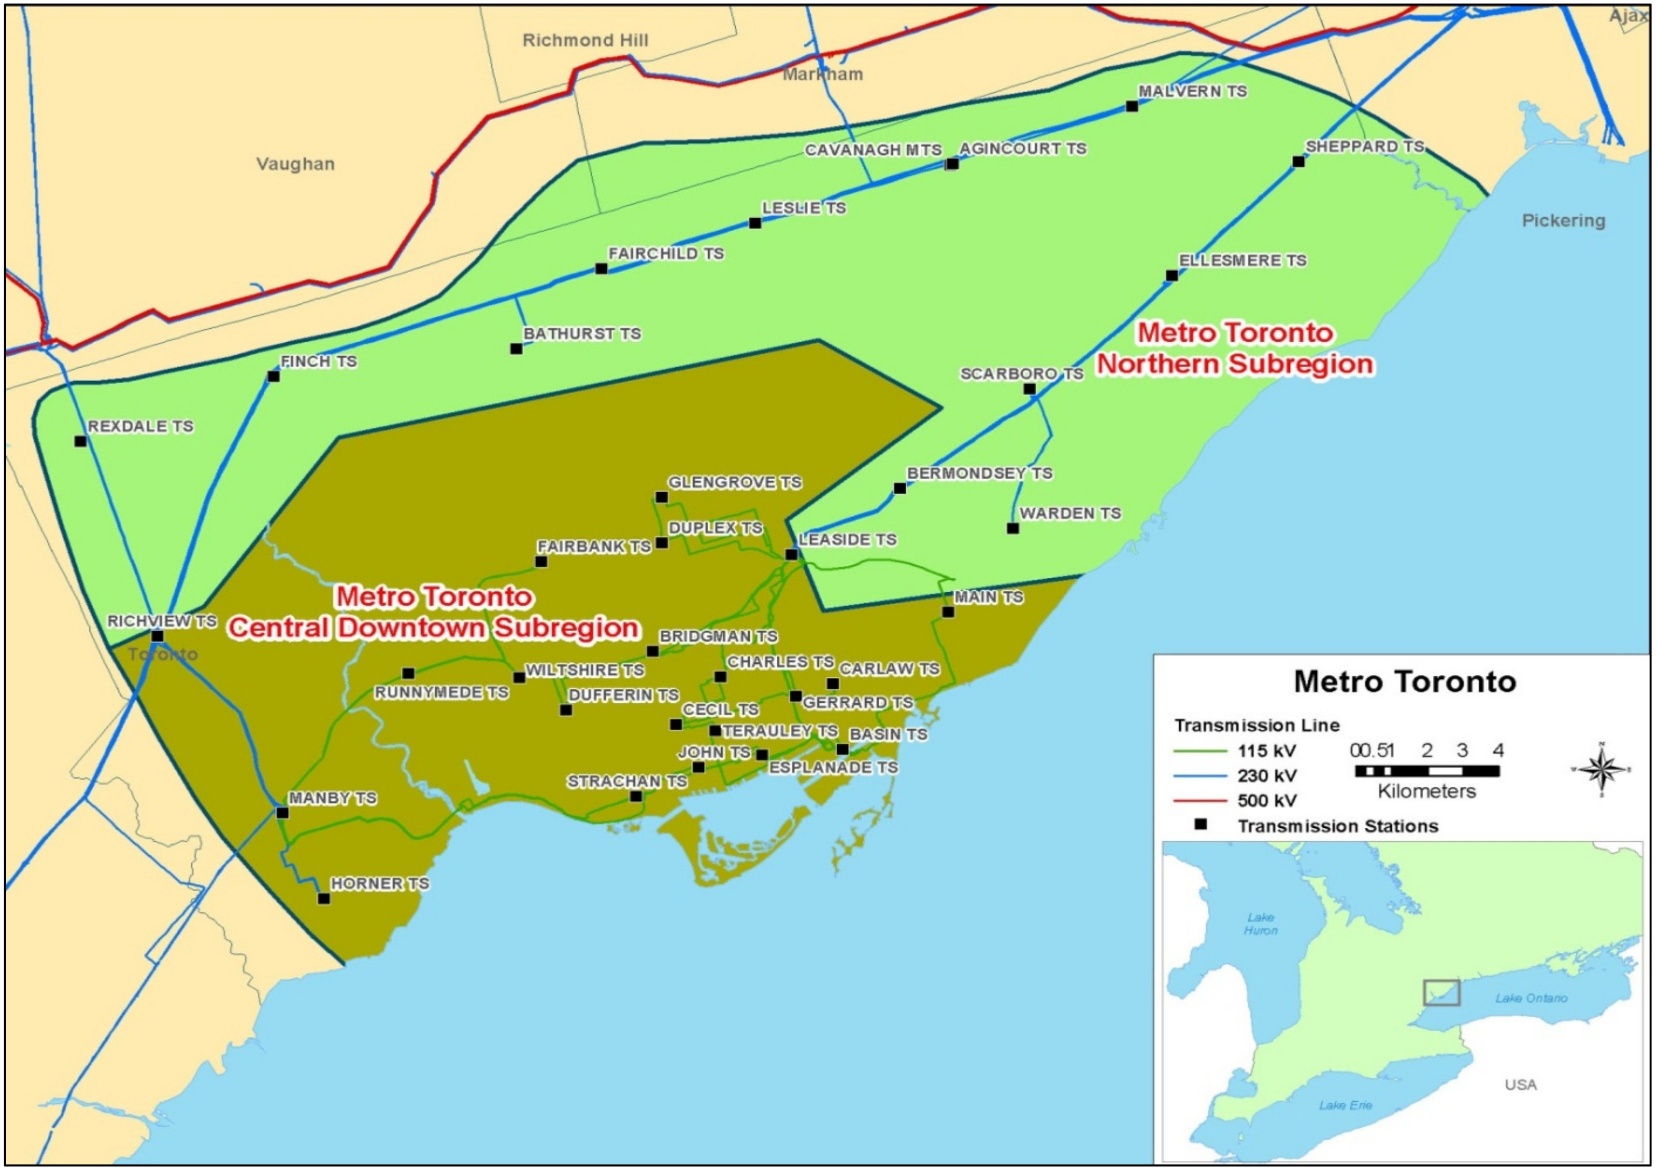

Figure 3-1 Metro Toronto Region – Supply Areas

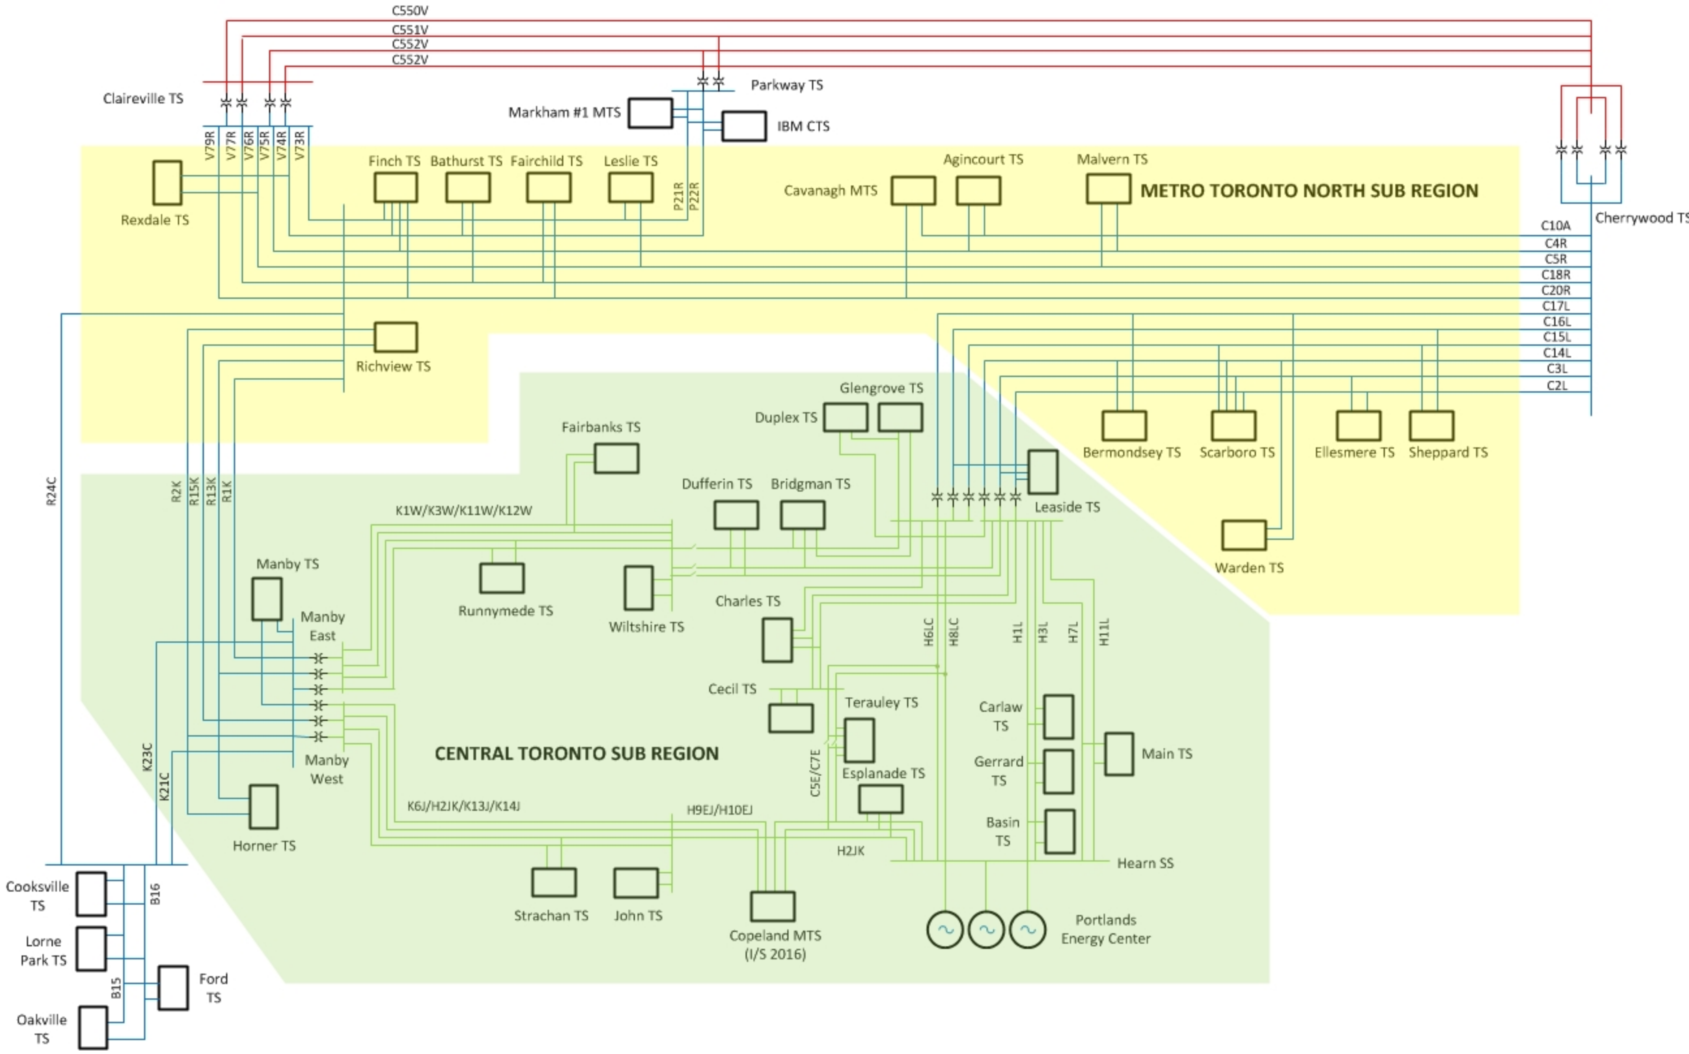

Figure 3-2 Metro Toronto Region – Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED AND/OR UNDERWAY OVER THE LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE METRO TORONTO REGION IN GENERAL AND THE TORONTO 115 KV NETWORK IN PARTICULAR.

These projects together with the new 550 MW Portlands Energy Centre that went into service in 2009 have ensured that the City continues to receive adequate and reliable supply. A brief listing of these projects is given below:

- Parkway 500/230 kV TS (2005) – built to provide adequate 500/230 kV transformation capacity following the retirement of Lakeview GS. The station while just outside the Metro Toronto Region is a key contributor in ensuring supply adequacy to the Region.

- John TS to Esplanade TS underground cable circuits (2008) – built to provide transfer capability between the Leaside TS and the Manby TS 115 kV areas.

- Incorporation of the 550 MW Portlands Energy Centre (2009) – covered modification to the Hearn 115kV switchyard to connect the new generation.

- 115 kV Switchyard Work at Hearn SS, Leaside TS & Manby TS (2013 & 2014) – covered replacement of the aging 115 kV switchyard at Hearn SS with a new GIS switchyard and replacement of all 115 kV breakers at Leaside TS and Manby TS.

- Manby 230 kV Reconfiguration (2014) – re-tapped Horner TS from the circuit R15K to R13K at Manby TS to balance / improve the distribution of loading on the 230 kV Richview TS to Manby TS system.

- Lakeshore Cable Refurbishment project (2015) – covered replacement of the aging K6J/H2JK 115 kV circuits between Riverside Jct. and Strachan TS.

- Midtown Transmission Reinforcement Project (expected completion by 2016) – covered replacement of the aging L14W underground cable and building an additional fourth 115 kV circuit between Leaside TS and Bridgman TS.

- Clare R. Copeland 115kV switching station (expected completion by 2016) – built to connect a new THESL owned 115/13.8 kV step-down transformer station in the downtown district.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the Metro Toronto Region is forecast to increase at an average rate of approximately 0.9% annually up to 2020, at 0.67% between 2020 and 2025 and at 0.61% beyond 2025. The growth rate varies across the region – from about 0.35% in the Northern Sub-Region to 1.07% in the City's downtown area over the 20 years.

Figure 5-1 shows the Metro Toronto Region's planning load forecast (summer net, non-coincident and regional-coincident extreme weather peak) under the IRRP high growth scenario. The regional-coincident (at the same time) forecast represents the total peak load of the 35 step-down transformer stations in the Metro Toronto. The coincident regional peak load is forecast to increase from 5176 MW in 2015 to 6196 MW by 2035.

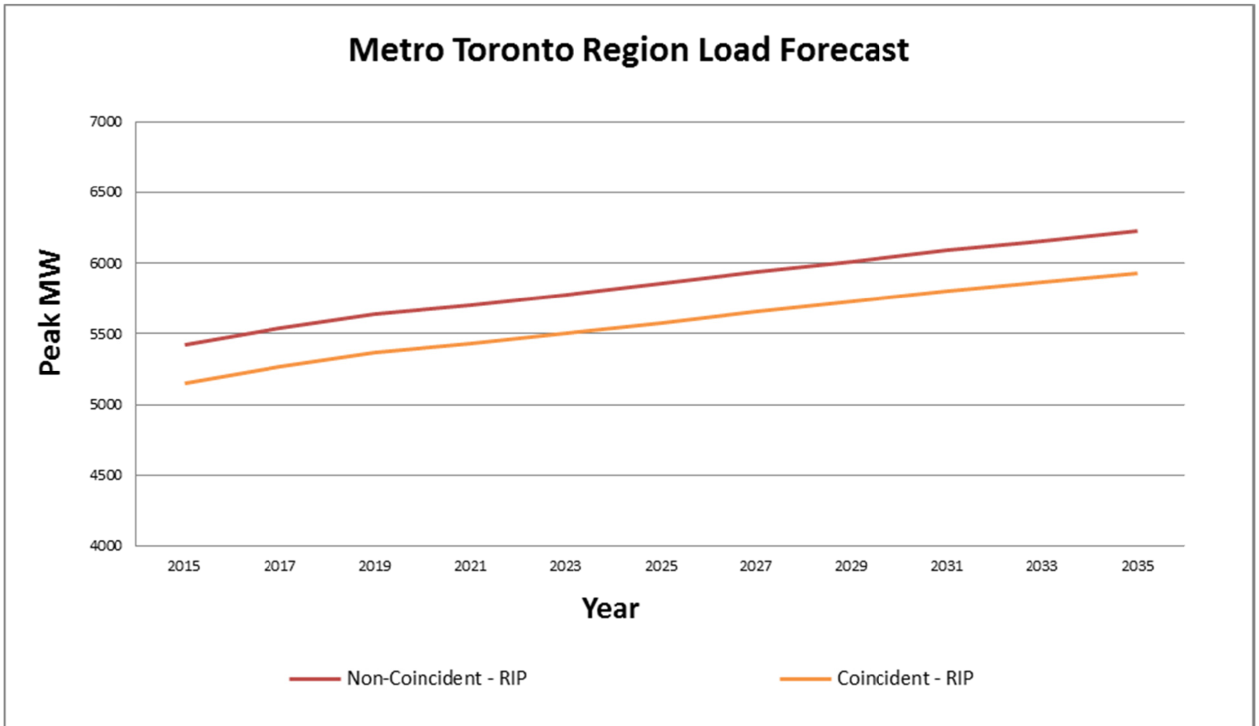

Figure 5-1 Metro Toronto Region Summer Extreme Weather Peak Forecast

The coincident and non-coincident extreme weather peak load forecast for the individual stations in the Metro Toronto Region is given in Appendix D. The coincident forecast represents the sum of the area stations peak load at the time of Metro Toronto Region peak demand and represents loads that would be seen by transmission lines and autotransformer stations and is used to determine the need for additional line and auto-transformation capacity. The non-coincident forecast represents the sum of the individual stations peak load and is used to determine the need for station capacity.

The individual station forecasts were developed by projecting 2015 summer peak loads, corrected for extreme weather, using the area stations growth rates as per the 2015 IESO's IRRP study (High Demand Scenario) for the Central Toronto Sub-Region [1] and as per the 2014 Hydro One's Need Assessment study [2] for the Metro Toronto Northern Sub-Region. The growth rates from [1] only account for existing Distributed Generation ("DG"), and do not include any new CDM and DG. The growth rates from [2] are the net growth rates seen by station equipment and account for CDM measures and connected DG. Details on the CDM and connected DG are provided in [1] and [2] and are not repeated here.

Impact of Metrolinx Go Transit Electrification

In June 2015, Metrolinx advised Hydro One that they are planning to proceed with the electrification of the Go transit rail system. This information was provided after the IRRP was completed in April 2015. Under their plan three Traction Power Stations (TPS) are proposed to be built in the Metro Toronto Region. These stations are as follows:

- Mimico TPS – For the Lakeshore West Go Transit Line (2020)
- Cityview TPS – For the Pearson Airport and Kitchener Go Transit lines (2020)
- Warden TPS – For the Lakeshore East Go Transit Line (2020)

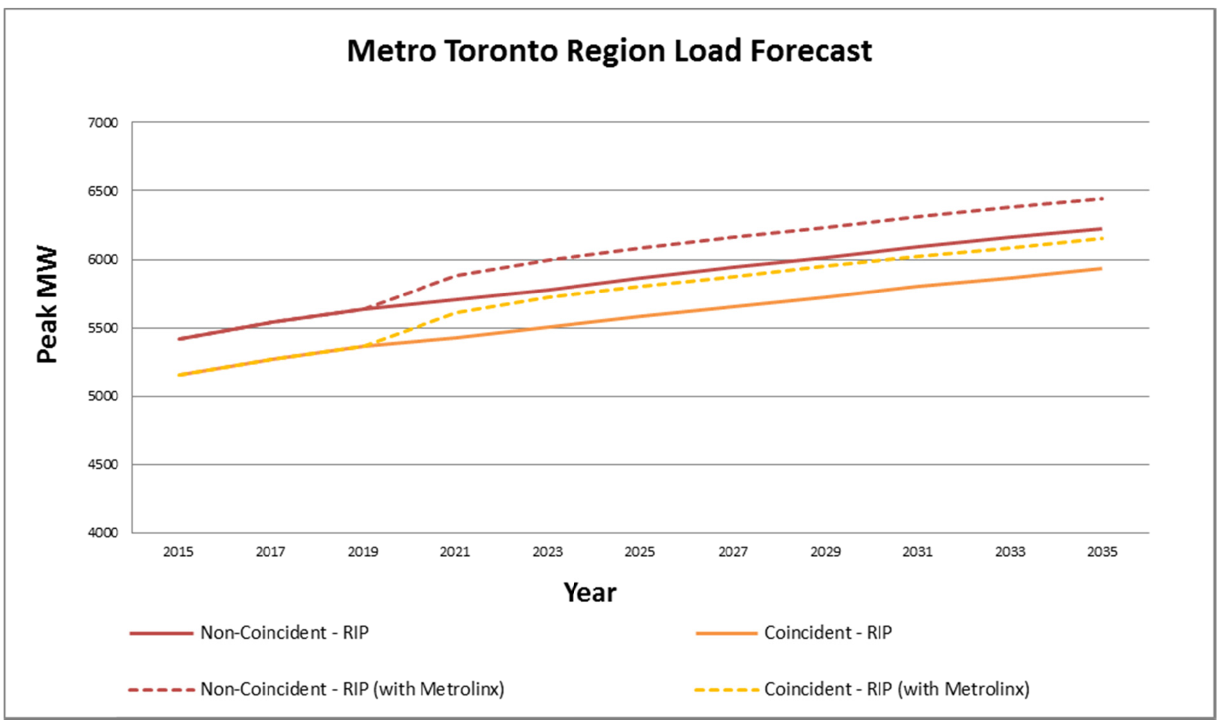

Figure 5-2 Effect of Metrolinx Electrification on the Metro Toronto Region Summer Peak Load

The impact of the Metrolinx load on the regional forecast is shown in Figure 5-2. Each of the three Metro area stations is expected to have an initial load of 40MW increasing to 80MW in 4 years. The net result is to increase the Region peak load by 240MW.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP Assessments is 2015-2035.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low voltage capacitor banks. Normal planning supply capacity for transformer stations in this Sub-Region is determined by the summer 10-Day Limited Time Rating (LTR).
- For THESL 13.8kV stations, an additional 95% factor is applied to the normal planning supply capacity in this study. This is to reflect the fact that all the capacity cannot be effectively utilized due to the large relative size of the individual customer loads.

6. ADEQUACY OF EXISTING FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE METRO TORONTO REGION OVER THE 2015-2035 PERIOD. IT ASSUMES THAT ALL PROJECTS CURRENTLY UNDER WAY ARE IN SERVICE.

Within the current regional planning cycle two regional assessments have been conducted for the Metro Toronto Region. The findings of these studies are input to the RIP. The studies are:

1) IESO's Central Toronto Integrated Regional Resource Plan – dated April 28, 2015[1]
2) Hydro One's Needs Assessment Report – Metro Toronto – Northern Sub-Region – June 11, 2014[2]

The IRRP and NA planning assessments identified a number of regional needs to meet the area forecast load demands. These regional needs are summarized in Table 6-1 and include needs for which work is already underway and/or being addressed by a LP study. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

A review of the loading on the transmission lines and stations in the Metro Toronto Region was also carried out as part of the RIP report using the latest Regional Forecast based on the IRRP high load growth scenario and as given in Section 5. The impact of Metrolinx Electrification on the regional infrastructure has been included.

For cases where a need was identified in the near or mid-term by the high growth scenario, a sensitivity analysis was done using the IRRP low growth scenario to get a range on the need date. Sections 6.1 to 6.2 present the results of this review. Additional needs identified as a result of the review are also listed in Table 6-1.

Table 6-1 Needs identified in Previous Stages of the Regional Planning Process

Type	Section	Needs	Timing
Station Capacity	7.1	West Toronto (Runnymede TS & Fairbank TS)	Today
	7.2	Southwest Toronto (Manby TS & Horner TS)	2020-2027
	7.3	Downtown District (JETC[1] Area)	2020+[2]
Transmission Line Capacity	7.4	230 kV Richview TS to Manby TS Corridor	2020-2023
	7.5	Circuit C10A (Duffin Jct. to Agincourt Jct.)	Completed
Supply Security, Reliability and Restoration	7.6	Breaker failure contingencies at Manby W and Manby E TS	2018/2021
	7.7	Breaker failure contingency at Leaside TS	Today
	7.8	Double circuit contingencies C2L/C3L or C16L/C17L (Cherrywood TS to Leaside TS)	2021
	7.9	Load Restoration – Northern Sub-Region (Bathurst TS, Fairchild TS, Leslie TS)	Today
Long-Term	7.10	115 kV Manby West To Riverside Jct. Lines	2035+
		230/115 kV Manby TS transformer capacity	2035+
		230/115 kV Leaside TS transformer capacity	2026+
Additional Long-Term Need Identified in RIP	7.10	Leaside TS x Wiltshire TS circuits	2034

[1] JETC denotes John TS, Esplanade TS, Terauley TS, and Copeland MTS which jointly supply the Downtown District.
[2] The need date will be around 2027 based on the station capacity consideration alone for the Downtown District stations. However, a need date of 2020+ was established by the WG based upon other considerations, such as requirements for spare feeder position. More details are given in Section 7.3.

6.1 Metro Toronto Northern Sub-Region

6.1.1 230kV Transmission Facilities

The Northern 230kV facilities consist of the following 230kV transmission circuits (Please refer to Figure 3-2):

a) Claireville TS to Richview TS 230kV circuits: V72R, V73R, V74R, V76R, V77R and V79R.
b) Cherrywood TS to Richview TS 230kV circuits: C4R, C5R, C18R and C20R.
c) Parkway TS to Richview 230kV circuits: P21R and P22R
d) Cherrywood TS to Agincourt TS 230kV circuit C10A.
e) Cherrywood TS to Leaside TS 230kV circuits: C2L, C3L C14L, C15L, C16L and C17L.

The Claireville TS to Richview TS circuits, the Cherrywood TS to Richview TS circuits and the Parkway TS circuits to Richview TS circuits carry bulk transmission flows as well as serve local area station loads within the Sub-Region. These circuits are adequate over the study period.

The Cherrywood TS to Agincourt TS circuit C10A is a radial circuit that supplies Agincourt TS and Cavanagh TS. The Need Assessment for the Metro Toronto Northern Sub-Region had identified that line capacity was restricted due to inadequate clearance from underbuilt street lighting and distribution line. Field surveys carried out by Hydro One have confirmed that the limiting underbuilds have been removed. The circuit is adequate over the study period.

The Cherrywood TS to Leaside TS 230kV circuits supply the Leaside TS 230/115kV autotransformers as well as serve local area load. Loading on these circuits is adequate over the study period.

6.1.2 Step-Down Transformer Station Facilities

The Sub-Region has the following step down transformer stations:

Agincourt TS	Leaside TS
Bathurst TS	Leslie TS
Bermondsey TS	Malvern TS
Cavanagh MTS	Rexdale TS
Ellesmere TS	Scarboro TS
Fairchild TS	Sheppard TS
Finch TS	Warden TS

The Metro Toronto Northern Sub-Region Needs Assessment Report had identified that the gross load was approaching station capacity at Cavanagh MTS and the Leslie TS (T1/T2, 27.6kV windings) and the Sheppard TS (T3/T4) DESN units. No action was recommended as the net load after considering the CDM and DG program is within ratings. The RIP report has reviewed the station loading and confirms that station capacity is adequate over the study period. However, the station loads will be monitored to ensure facility ratings are not exceeded.

6.2 Central Toronto Sub-Region

6.2.1 230kV Transmission Facilities

The 230kV transmission facilities in the Central Toronto Sub-Region are as follows (Please refer to Figure 3-2):

a) Richview TS x Manby TS 230kV circuits: R1K, R2K, R13K and R15K
b) Cooksville TS x Manby TS 230kV circuits: K21C/K23C
c) Manby TS 230/115kV autotransformers
d) Leaside TS 230kV/115kV autotransformers

The Richview TS to Manby TS circuits and the Cooksville TS to Manby TS circuits supply the Manby 230/115kV autotransformer station as well as Horner TS. Please note that the K21C and K23C circuits connect back to Richview TS through Cooksville TS and 230kV circuit R24C.

Table 6-2 summarizes the result of adequacy studies and gives the need date for transmission reinforcement for each of the above facilities.

Table 6-2 Adequacy of 230kV Transmission Facilities

Facilities	2015 MW Load(1)	MW Load Meeting Capability (LMC)	Limiting Contingency	Need Date
Richview x Manby 230kV Corridor	1456	1540	R2K	2020-2023(2)
Manby E. 230/115kV autos	330	560	T2	2035+
Manby W. 230/115kV autos	397	612	T9	2035+
Leaside 230/115kV autos + Portlands GS(1)	1340	1525-1915(3)	None	2026+(4)

(1) The loads shown have been adjusted for extreme weather.
(2) The 2020 and 2023 need dates correspond to the high growth and low growth rate scenarios without considering Metrolinx Mimico TPS. Assuming Metrolinx Mimico TPS comes into service in 2020, the need date will become 2020 under both scenarios.
(3) The Leaside 115kV area is supplied by the Leaside TS 230/115kV autotransformers and the 550MW Portlands GS. Load Meeting capability is dependent on the generation from Portlands GS which backs up the flow through the Leaside autotransformers. The 1525MW LMC assumes only 160MW generation at Portland GS while the 1915MW LMC assumes the full 550MW generation at Portland GS.
(4) The need date is based on the 1525MW LMC which assumes that two of the three units are out at Portlands GS and total plant generation is 160MW.

6.2.2 115kV Transmission Facilities

The 115kV facilities in the Metro Toronto Region (see Figure 3-2) can be divided into five main corridors:

1. Manby TS East x Wiltshire TS – Four circuits K1W, K3W, K11, K12W. Forecast loading can exceed corridor rating under certain conditions. More details are provided in Section 7.1.2.
2. Manby TS West x John TS – Four circuits H2JK, K6J, K13J and K14J. These circuits are adequate over the study period.
3. Leaside TS x Hearn TS – Six circuits H6LC, H8LC, H1L, H3L, H7L and H11L. These circuits are expected to be adequate over the study period. .
4. Leaside TS x Cecil TS – Three circuits L4C, L9C, and L12C. These are expected to be adequate over the study period.
5. Leaside TS x Wiltshire TS – Four circuits L13W/L14W/L15/L18W. The L18W circuit is expected to go into service in summer 2016. Loading will exceed corridor rating by 2034 for loss of the L18W circuit. More details are provided in Section 7.10.4.

The loading on the limiting sections is summarized in Table 6-3.

Table 6-3 Overloaded Sections of 115kV circuits

Facilities	2015 MW Load	MW Load Meeting Capability	Limiting Contingency	Need Date
Manby TS x Wiltshire TS 115kV Corridor	330	348/410(1)	K11W	2019-2023(1)
Leaside TS x Wiltshire TS	310	350	L18W	2034

(1) The Manby x Wiltshire corridor provides emergency backup for Dufferin TS load under Leaside area contingencies. Assuming that a 100MW of back up capability is provided, the maximum load that can be supplied in the Fairbanks/Runnymede area is 348MW and the need date for upgrading the corridor is 2019. If 75MW of back up capability is required, the need date will become 2023. However, if back up capability during peak is not considered, maximum load meeting capability is 410MW. The need in this case would be beyond 2035.

6.2.3 Step-Down Transformer Facilities

There are a total of 20 step-down transformers stations in the Central Toronto Sub Region.as follows:

Basin TS	Esplanade TS	Fairbank TS
Bridgman TS	Gerrard TS	Copeland MTS
Carlaw TS	Glengrove TS	John TS
Cecil TS	Main TS	Strachan TS
Charles TS	Terauley TS	Horner TS
Dufferin TS	Wiltshire TS	Manby TS
Duplex TS	Runnymede TS	

The stations non-coincident loads are given in Appendix D Table D-1. The areas and the stations requiring relief are given in Table 6-4.

Table 6-4 Adequacy of Step-Down Transformer Stations - Areas Requiring Relief

Area/Supply	Capacity (MW)	2015 Loading (MW)	Need Date
West Toronto: Fairbanks TS and Runnymede TS	285	291	Now
Southwest Toronto : Manby TS and Horner TS area	400	376	2020-2027 (1)
Downtown Toronto: John TS, Esplanade TS, Terauley TS and Copeland MTS (JETC)	739	632	2020+ (2)

(1) The need dates are based on high and low demand growth rates scenario

(2) The need date will be around 2027 based on the station capacity consideration alone for the Downtown District stations. However, a need date of 2020+ was established by the WG based upon other considerations, such as requirements for spare feeder position. More details are given in Section 7.3.

7. REGIONAL NEEDS AND PLANS

THIS SECTION DISCUSSES THE ELECTRICAL SUPPLY NEEDS FOR THE METRO TORONTO REGION AND SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THE NEEDS. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE IRRP FOR THE CENTRAL TORONTO SUB-REGION [1] AND THE NA FOR THE METRO TORONTO NORTHERN SUB-REGION [2] AS WELL AS THE ADEQUACY ASSESSMENT CARRIED OUT AS PART OF THE CURRENT RIP REPORT.

7.1 West Toronto Area

7.1.1 Station Capacity - Runnymede TS & Fairbank TS

Runnymede TS and Fairbank TS are 115/27.6 kV transformer stations that supply the load demand in the west end of Toronto. The two stations are connected to the 115 kV Manby East transmission system and have been operating at or near their capacity limits for the last five years. THESL has managed growth by transferring loads to adjacent area stations.

The area 2015 extreme weather peak load was 291 MW and exceeded the stations capacity of 285MW. The area is experiencing some re-development and the proposed Eglinton Crosstown Light Railway Transit (“LRT”) project by MetroLinx will add an additional 14 MW of load to Runnymede TS in 2021. Additional step down transformation capacity is required now to provide relief and be able to meet the forecast load demand.

7.1.2 Line Capacity - Manby TS x Wiltshire TS 115kV circuits

The Manby TS x Wiltshire TS four circuit 115kV tower line carries circuits K1W, K3W, K11W and K12W. These circuits supply Fairbanks TS, Runnymede TS and well as Wiltshire TS. Under Leaside area outage conditions, these circuits are also used to pick up all or parts of Dufferin TS and/or Bridgman TS loads. The total corridor capability is dependent on the Fairbanks TS and Runnymede TS load and the load picked up and is given in table below:

Table 7-1 Manby x Wiltshire Corridor Capability

Year	Fairbanks TS, Runnymede TS, and Wiltshire TS Load Forecast (MW)	Amount of Dufferin TS and Bridgman TS Load that can be picked up (MW)	Total Corridor Capability (MW)
2015	330	120	450
2019	349	97	446
2023	375	68	443
2027	390	46	436
2031	399	25	424
2035	406	10	416

The timing of the Manby TS x Wiltshire TS circuits upgrade is dependent on the backup capability desired. If backup capability is not considered, the upgrade can be deferred to beyond 2035. However, if at least 70MW of back up capability - equal to about half of Dufferin TS load - is deemed appropriate, the upgrade would be deferred to about 2023.

Figure 7-1 West Toronto Area - Fairbank TS and Runnymede TS

7.1.3 Recommended Plan and Current Status

The Working Group has considered and reviewed several options to provide additional transformation capacity in West Toronto area as part of the Central Toronto IRRP. Based upon the review, and consistent with the IRRP Working Group recommendation is to expand Runnymede TS by adding two 115/27.6 kV 50/83 MVA transformers and a 27.6kV switchyard with six feeders. This work is required to be completed as early as possible.

The Working Group also recommends that the Manby TS to Wiltshire TS tower line carrying circuits K1W/K3W/K11W/K12W be also upgraded at the same time. This option would maintain the load transfer capability between Leaside TS and the Manby TS under emergency or outage conditions in addition to supplying future load growth in the West Toronto Area.

The estimated total cost of the work is approximately $90 M, which includes $34 M for the station work at Runnymede TS, $16 M for the upgrade of four 9.5 km long circuits between Manby TS and Wiltshire TS and $40 M for distribution facilities by THESL. The transmission cost of $50M is expected to be recovered in accordance with the TSC.

Hydro One has initiated development work on the project covering preparation of estimates and obtaining of EA approvals. The estimate is expected to be completed by the end of Q2 2016. It will also confirm if the targeted in-service date of May 2019 for this project is achievable. A Section 92 application will be submitted in 2016.

7.2 Southwest Toronto Area

7.2.1 Station Capacity – Southwest Toronto (Manby TS & Horner TS)

Manby TS and Horner TS are two 230/27.6 kV transformer stations supplying the load demand in the southwest end of Toronto (see Figure 7-2). Based on the current RIP forecast the 400MW combined station capacity of the stations is forecast to be exceeded by summer 2020. Additional step down transformation is required to provide relief.

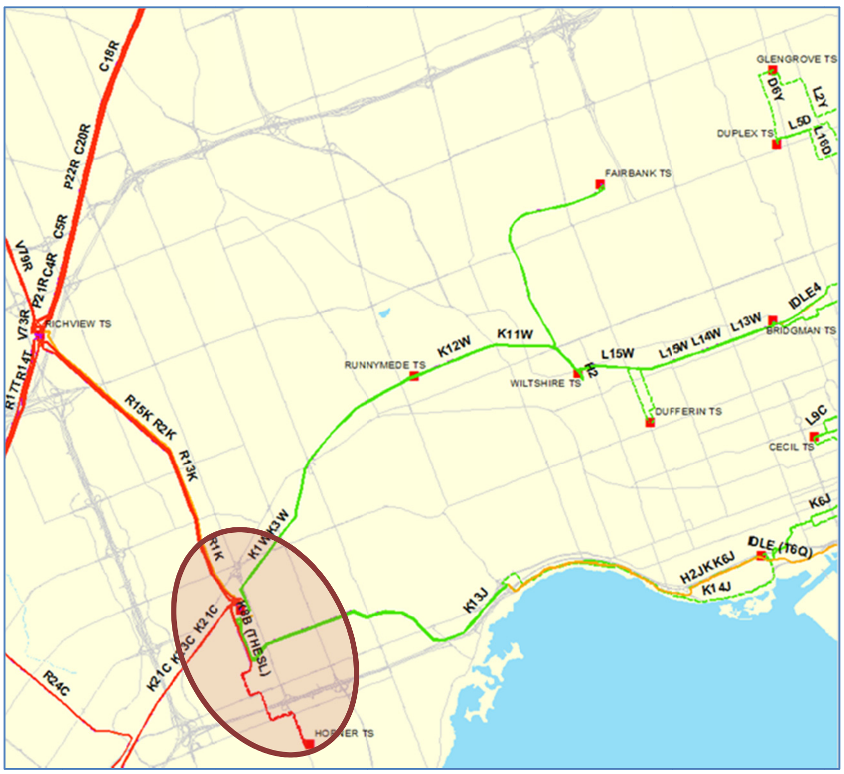

Figure 7-2 Horner TS and Manby TS Supply Area

7.2.2 Recommended Plan and Current Status.

To address the need for additional step down transformation capacity in the Southwest Toronto area, the Working Group's recommended building a second 230/27.6 kV DESN at the existing Horner TS site. Two 75/125MVA transformers will be installed at the station along with a new 27.6kV switchyard. Load transfer out of Manby TS to Horner TS is required to relieve Manby TS as the loading at that station exceeds its capacity. New distribution feeder ties are required to be built between Manby TS and Horner TS by THESL.

The estimated total cost of the work is about $53M, which includes $34 M for the station work at Horner TS and $19M for THESL distribution facilities. The transmission cost of $34M is expected to be recovered in accordance with the TSC.

Hydro One has initiated development work on the project covering preparation of estimates and obtaining of EA approvals at the request of THESL. The current in-service date for the project is expected to be May 2020.

7.3 Downtown District

7.3.1 Station Capacity – JETC[2] Area

The Toronto Downtown Core area is mainly supplied by the three existing 115/13.8 kV stations: John TS, Esplanade TS, and Terauley TS. John TS is connected to the Manby West system while Esplanade TS and Terauley TS are fed from the 115 kV Leaside / Hearn system. (see Figure 7-3)

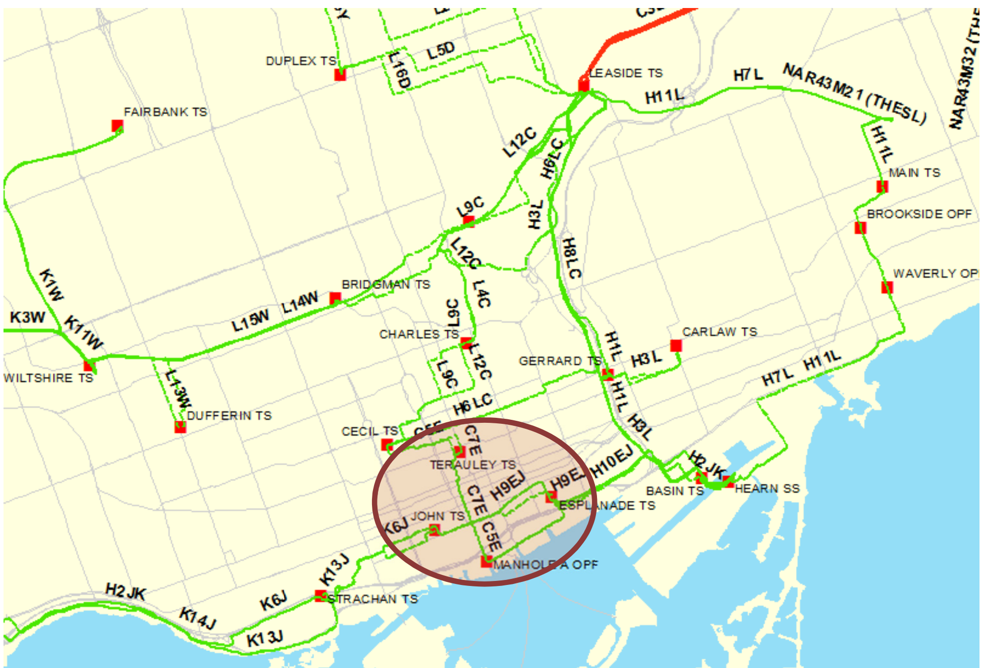

Figure 7-3 Toronto Downtown Supply Area

John TS was built in the 1950's and the THESL switchgear at the station is approaching end of life. THESL is building a new 115/13.8kV owned transformer station, Copeland MTS in the Downtown

[2] JETC denotes John TS, Esplanade TS, Terauley TS, and Copeland MTS which jointly supply the Downtown District.

District near John TS with normal supplied from the 115 kV Manby West system. The station first phase capacity will be around 130 MVA and it is expected to be in service in 2016. Copeland MTS will provide a new source of supply to the area customers and facilitate the replacement of end of life switchgear at John TS.

With the new Copeland MTS in-service in 2016, adequate transformation capacity will be available in the Downtown District till 2027. However, most of this capacity will be at John TS as 13.8kV buses at both Terauley TS and Esplanade TS are at or approaching capacity limits. THESL anticipates that the need for new transformation facility is more advanced due to limited spare feeder positions available at John TS for new customer connection and load transfer required to facilitate the refurbishment work at John TS. At the current pace of development in these areas, both bus and feeder position in the Downtown Core area are expected to be at or near capacity within five to ten years[3]. Specific issues identified by THESL Hydro are as follows:

- By 2019 THESL forecasts that two busses will be overloaded (ie. loaded beyond 10 Day LTR) at George and Duke MS and two busses overloaded at John/Windsor TS.
- By 2025 THESL forecasts that one bus will be overloaded at Copeland TS, two busses overloaded at George and Duke MS and three busses overloaded at John/Windsor TS.
- At John/Windsor TS, four out of six busses have no spare feeder positions to connect new customers. One bus has a single spare feeder position and one bus has two spare feeder positions.
- At George and Duke MS, one bus has no spare feeder positions and one bus has six spare feeder positions.
- At Esplanade TS, there is only one bus with three spare feeder positions.
- Once in service, Copeland TS is forecasted to have six and three spare positions on each its two busses, respectively.

7.3.2 Recommended Plan and Current Status

Based on the current information, the need to relieve the stations in Downtown District is expected to be beyond 2020. However, the need date may get delayed or brought forward if the load growth in this area is slower or faster than currently anticipated. The Working Group recommends that this need and timing should be further refined by THESL through their distribution planning process and included in updates to the IRRP and RIP. The uptake of CDM and DG should be preserved and re-assessed.

In the case where CDM and DG are deemed insufficient, building Copeland Phase 2 and installing additional transformers and two new buses at Copeland MTS site is the most cost effective way to meet the required THESL needs. The site and the high voltage switching facilities required to accommodate this expansion (Copeland Phase 2) are already included as part of the Copeland MTS Phase 1 project.Copeland MTS is an underground station and is not located adjacent to residential land uses. The THESL estimated cost for Copeland MTS Phase 2 to be approximately $46 M.

[3] Further information may be found in THESL's rate application EB-2014-0116 to the Ontario Energy Board

7.4 Transmission Line Capacity – 230 kV Richview TS to Manby TS Corridor

7.4.1 Description

The 230 kV transmission corridor between Richview TS and Manby TS is the main supply path for the Western Sector of Central Toronto Sub-Region. It also supplies the load in the southern Mississauga and Oakville areas via Manby TS. Along this Corridor there are two double circuit 230kV lines R1K/R2K and R13K/R15K. In addition the corridor contains an idle double circuit 115kV line. Figure 7-4 shows the area supplied by Richview TS x Manby TS circuits.

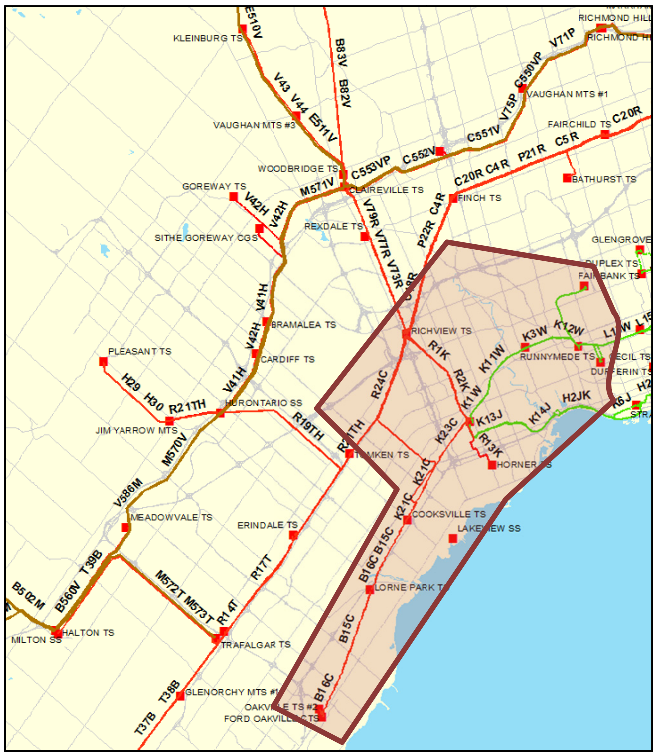

Figure 7-4 Richview x Manby Supply Area Map

The forecast loading on the Richview TS to Manby TS circuits is given in Table 7-2 below for both the high growth and low growth scenarios. The loads include the 115 kV Manby East, 115 kV Manby West, 230 kV Manby, and 230 kV Oakville-Cooksville loads. The need date for providing relief is 2020 for the high growth scenario and 2023 for the low growth scenario.

Table 7-2 also shows the effect of Metrolinx Mimico TPS on the need date for relief. In both scenarios, relief is required by 2020. The magnitude of Metrolinx load is large enough to trigger the reinforcement.

Again, due to the large incremental load from Mimico TPS, CDM will not be sufficient to help eliminate or even defer the need date for the transmission reinforcement. Transmission reinforcement is required to be implemented before the Mimico TPS can be connected.

Table 7-2 Coincident RIP MW Load Forecast for Richview TS x Manby TS Area

	Limit	2015	2017	2019	2021	2023	2025	2027	2029	2031	2033	2035
Base - Without Metrolinx Mimico TPS load												
High Growth	1540	1456	1488	1536	**1580**	1617	1646	1674	1698	1722	1742	1763
Low Growth	1540	1456	1481	1503	1530	**1544**	1557	1566	1572	1577	1597	1617
With Metrolinx Mimico TPS load												
High Growth	1540	1456	1488	1536	**1640**	1697	1726	1754	1778	1802	1822	1843
Low Growth	1540	1456	1481	1503	**1590**	1624	1637	1646	1652	1657	1677	1697

7.4.2 Alternatives Considered

The following alternatives are currently under consideration:

Upgrade four existing 230kV Richview TS x Manby TS circuits: Re-conductor with higher-capacity conductors on existing towers. Hydro One will check the feasibility of this option without major tower modifications and also in terms of outages arrangement. The estimated total cost of this option is about $16M, assuming that no major tower modifications and no bypass lines during re-conductoring are required.

Rebuild existing 115kV Richview TS x Manby TS line: Rebuild the existing idle 115 kV double-circuit line as a 230kV double-circuit line. The new 230 kV line is to share the existing terminations for circuits R2K and R15K at Richview TS and Manby TS. The ampacity of the new conductors are to be equal to or better than that of the existing circuits, effectively doubling the ampacity of R2K and R15K. This alternative requires the replacement of all the existing 115 kV towers with 230 kV towers. The estimated total cost of this option is about $19.5M.

Build two new 230 kV Richview TS x Manby TS circuits: Similar to the second alternative above, rebuild the two existing idle 115 kV double-circuit line as a 230kV double-circuit line. New terminations for these circuits are required at Richview TS and Manby TS. The ampacity of the new conductors are to be equal to or better than that of the existing circuits. This alternative not only provides higher transmission capacity but also increases the supply reliability to the Central Downtown and Southwest GTA area. The estimated total cost of this option is around $39.5M due to the extra station work required at the Richview TS and Manby TS.

Extend the Cooksville TS x Oakville TS line to Trafalgar TS: Extend the Cooksville TS x Oakville TS 230kV double circuit line B15C/B16C about 8km to Trafalgar TS where new 230kV switching facilties are also required. This alternative increases supply capacity and reliability to Southwest GTA area from Trafalgar TS, and thus alleviates the loading on the Richview x Manby corridor. The total estimated cost of this line and station work is around $54M.

CDM & DG: According to Central Toronto IRRP report, the potential DG development, targeted demand response and the potential incremental demand response in these areas supplied by Manby TS may defer the need for this transmission reinforcement by several years, depending on the load growth rate. However, with Mimico TPS connected near Horner TS, these targeted and potential incremental demand response will not be adequate due to the size of the extra load added by the TPS.

The Maintain Status Quo or Do Nothing alternative was not considered as it does not provide relief for the Richview x Manby transmission lines.

7.4.3 Recommended Plan and Current Status

The Metrolinx Mimico TPS information is new and was provided as part of the RIP after the IRRP was completed in April 2015. If this TPS is going to be in-service as planned in 2020, CDM initiatives will not effectively defer the need date for this transmission corridor because of the size of the additional load. Therefore, upgrading the existing Richview x Manby corridor or new supply path for the areas served by Manby TS will be required before the Metrolinx Mimico TPS can be connected.

The Trafalgar x Oakville line alternative, at $54M, is the highest cost alternative ($14.5M higher than the next most expensive alternative) and there is a risk that it may not be able to be completed in time to connect the the Metrolinx Mimico TPS in 2020. This alternative may also trigger the need for additional transformation facilities and thus would incur additional costs.

As a result, Working Group recommends that Hydro One proceed with the development and estimate work on the first three alternatives listed in Section 7.4.2 in 2016. Both EA and Section 92 approvals will be required and it is expected to take at least 3-4 years for the implementation of a wire solution. The Working Group will select the preferred alternative by December 2016. Hydro One will then plan to initiate project execution by summer 2018 in order to enable the connection of MetroLinx Mimico TPS by summer 2020.

7.5 Transmission Line Capacity – Circuit C10A (Duffin Jct. to Agincourt Jct)

C10A is a 20 km long radial circuit in Metro Toronto Northern Sub-Region from Cherrywood TS supplying Agincourt TS and Cavanagh MTS. The Metro Toronto Northern Sub-Region NA identified that the capacity of this circuit was thermally limited by a section approximately 4 km long between Duffin Jct. and Agincourt Jct. The flow on this section of the circuit might exceed its long-term emergency (LTE) rating under summer peak load conditions following certain contingencies.

A preliminary study based on the old field survey data was done in July 2015. The old record showed that the LTE rating was limited by some underbuilds along the line section. A new field survey was then carried out in October 2015. It was discovered that the aforementioned underbuilds had been previously removed, and the LTE rating of this line section should be 840A. The record is being updated. No further action is required.

7.6 Breaker Failure at Manby TS

7.6.1 Description

The failure of any of the Manby TS breakers A1H4 and H1H4 in the Manby West 230kV yard and the breaker H2H3 in the Manby east 230kV yard can cause the outage of any two of the three 230/115kV autotransformers at either the west or east yard of Manby TS. This may result in the overload of the remaining autotransformer. Based on the Coincident RIP Forecast the need date for the work is summer 2018 and summer 2021 for Manby West and Manby East respectively.

7.6.2 Recommended Plan and Current Status

The Working Group has recommended that installation of a Special Protection Scheme (SPS) is the most cost effective means to mitigate the breaker failure risk.

Hydro One is working on the development and estimate work for the SPS at Manby TS. The preliminary estimate for this work is approximately $2M and this will be updated when the development work is complete by summer 2016. The planned in-service of this work is summer 2018.

7.7 Breaker Failure at Leaside TS

The failure of breaker L14L15 at Leaside TS can cause the outage of two of the Leaside TS to Bridgman TS circuits. This may result in the loss of Transformers T11, T12, T14 and T15 at Bridgman TS. Under this scenario, two of the four LV buses will be lost by configuration. Only transformer T13 remains in service and supplies buses HLA1 and HLA7.

The 15 minute LTR for the X and Y windings of Transformer T13 is 55MVA. Therefore, as long as the loading on the HLA1 and HLA7 does not exceed the 15 minutes LTR, the operator can take action to reduce load to within transformer LTE ratings.

A new normally open switch is being installed at Bridgman TS as part of the Leaside-Bridgman Transmission Reinforcement project. This new switch can be closed remotely following the loss of the circuit L15W to resupply the two Bridgman transformers from the circuit L13W. This will alleviate the loading of the transformer T13 and the circuit L18W. and any possible voltage issue at Bridgman TS. Therefore, no investment is recommended.

7.8 Cherrywood to Leaside (CxL) Double Circuit Contingencies

Double circuit contingencies involving the lines C2L/C3L or C16L/C17L from Cherrywood TS to Leaside TS (CxL) can result in the loss of two of the three 230/115kV autotransformers on the same half of Leaside TS. The long-term emergency rating of the remaining autotransformer may be exceeded if only a single combustion unit at the Portland Energy Centre (PEC) is available, coincident with either of the abovementioned double contingencies during peak load condition.

The Working Group recommends that no further work is required in the near- and mid-term as there is already an existing operating instruction in place to cover the overload issue of the remaining Leaside autotransformer by closing the 115kV bus-tie at Leaside TS.

7.9 Load Restoration – Northern Sub-Region (Bathurst TS, Fairchild TS, Leslie TS)

Bathurst TS, Fairchild TS, and Leslie TS are supplied by the 230 kV Richview x Cherrywood x Parkway system in the Metro Toronto Northern Sub-Region. Following two circuit contingencies, approximately 240-300 MW of load during summer peak time could be lost during each contingency scenario, as follows:

Table 7-3 Maximum Load Loss during Two Circuit Contingencies

Double Element Contingency	Station Connected	Non-Coincident Load Forecast (MW)	
		2015	2025
P22R + C18R	Bathurst TS	271	279
C18R + C20R	Fairchild TS	292	301
P21R + C5R	Leslie TS	239	249

There are currently no existing transmission switching facilities to allow load restoration immediately. Partial load could be restored via distribution transfer to the nearby stations.

For Bathurst and Leslie cases, the stations are supplied by circuits on separate transmission lines for all or most sections. The probability of occurrence of overlapping outages on circuits on different tower lines is extremely low. The supplied circuits for Fairchild TS are on common tower for two-third of the line (approximately 32km).

Based on the outage records in the past 25 years there has been no incidence of any double contingencies described above.

A single transformer station would require four motorized disconnect switches to be useful. Typical cost for installing these transmission switching facilities per station would be between $8-10M.

Based on the low probability of frequency of such events versus the high mitigation cost, the Working Group recommendation is that no further action is required.

7.10 Long Term Needs

Four longer term needs had been identified in the Central Toronto IRRP as follows:

- Transmission Line Capacity – 115 kV Manby West To Riverside Junction
- Transformation Capacity – 230/115 kV Manby TS
- Transformation Capacity – 230/115 kV Leaside TS
- Leaside TS x Wiltshire TS 115kV circuits

Loading on Manby TS and the Manby TS x Riverside Junction circuit are within ratings over the study period under the Coincident RIP forecast. The Working Group recommendation is that no further action is required.

The Leaside TS transformer and the Leaside TS x Wiltshire circuits will require relief in the long term. This issue will be considered in the next planning cycle. The Working Group recommendation is that no further action is required. However, Hydro One and IESO will continue to monitor loads and initiate necessary relief measures, if required.

8. CONCLUSIONS AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE METRO TORONTO REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in the Table 8-1 below.

Table 8-1 Regional Plans – Needs Identified in the Regional Planning Process

No.	Need Description
I	Supply Security – Breaker Failure at Manby West & East TS
II	West Toronto Area - Station Capacity and Line Capacity
III	Southwest Toronto - Station Capacity
IV	Downtown District - Station Capacity
V	230 kV Richview x Manby Corridor– Line Capacity
VI	Leaside Autotransformers
VII	Line Capacity – 115 kV Leaside x Wiltshire Corridor

Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the near-term and mid-term needs are summarized in the Table 8-2 below. Investments to address the long-term needs where there is time to make a decision (Need No. VI & VII), will be reviewed and finalized in the next regional planning cycle.

Table 8-2 Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

Id	Project	Next Steps	Lead Responsibility	I/S Date	Est. Cost	Needs Mitigated
1	Manby SPS	Transmitter to carry out the work	Hydro One	2018	$2M	I
2	Runnymede Expansion & 115 kV Manby x Wiltshire Corridor Upgrade	Transmitter to carry out the work	Hydro One	2019	$90M	II
3	Horner Expansion	Transmitter to carry out the work	Hydro One	2020	$53M	III
4	230 kV Richview x Manby Corridor Upgrade	Transmitter to carry out the work	Hydro One	2020	$20-40M	V
5	Copeland Phase 2	LDC to carry out work & monitor growth	THESL	2020+	$46M	IV

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered every five years. The next planning cycle for the Metro Toronto Region is expected to be started in 2018. However, the Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the regional planning cycle will be started earlier to address the need.

Appendix E. List of Acronyms

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH INPUT AND SUPPORT FROM THE WORKING GROUP IN ACCORDANCE TO THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE NORTHWEST ONTARIO REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator
- Hydro One Networks Inc. (Distribution)
- Atikokan Hydro Inc.
- Kenora Hydro Electric Corporation Ltd.
- Thunder Bay Hydro Electricity Distribution Inc.
- Sioux Lookout Hydro Inc.
- Fort Frances Power Corporation

This RIP is the final phase of the regional planning process and it follows the completion of Integrated Regional Resource Plan ("IRRP") by the IESO for the North of Dryden Sub-Region in January 2015, Greenstone-Marathon Sub-Region in June 2016, and West of Thunder Bay in July 2016 and for Thunder Bay Sub-Region in December 2016 [2-5]. This report also references the IESO Draft Remote Community Connection Plan report [6].

This RIP provides a consolidated summary of needs and recommended plans for North of Dryden, Greenstone-Marathon, West of Thunder Bay, and Thunder Bay Sub -Regions that make up the Northwest Ontario Region. The potential needs of the bulk system is not within the scope of the Regional Planning, however, some aspects of the bulk system needs and plans are discussed in this report in the context of regional plans.

The Working Group has reassessed and updated the LDC load forecasts, which have remained consistent with the forecasts used in the IRRPs. Accordingly, this RIP has confirmed the needs and the proposed or recommended infrastructure (wires) plans for the sub-regions as indicated in the IRRP reports.

The needs in the region are largely driven by the industrial load growth, particularly the mining sector. Considering the uncertainties in the forecast of the industrial loads, this RIP uses the forecast scenarios and assumptions developed for the Northwest IRRPs. The connection of remote communities to the electricity grid, as well as the load growth as a result of economic developments, are also contributing factors. Since the development timelines and plans for connection of the mining and other industrial loads are uncertain and frequently depend on the customer decision, the IRRP and RIP have both considered low, medium (or reference) and high load growth scenarios and identified alternatives and recommended plans to address the needs under each scenario in near-term (present-5 years), mid-term (5-10 years) and long term (10-20 years).

The following is the summary of the currently recommended or proposed near/mid/long-term wires plans for the sub-regions under low, medium and high load growth scenarios. The current status of these plans is also indicated in the following.

North of Dryden Sub-Region Wires Plans

No.	Need	Wires Options	Load Growth	Term	Status
1	Circuits E1C and E4D Capacity	A 230 kV transmission line from Dryden/Ignace area to Pickle Lake	Medium[1]	Near-term	Recommended in IRRP. Development has started.
2	Circuits E4D and E2R Capacity	Upgrade of transmission lines E2R and E4D, and additional voltage support	All Scenarios	Near-term	Recommended in IRRP. The need has not materialized.
3		A 115 kV or 230 kV transmission line from Dryden to Ear Falls	High	Long-term	Proposed in IRRP. Not needed in the planning horizon, assuming Projects 1 and 2 proceed.

Greenstone-Marathon Sub-Region Wires Plans

No.	Need	Wires Options	Load Growth	Term	Status
4	Circuit A4L Capacity	Upgrade of sections of transmission line A4L, and dynamic voltage support devices at Geraldton	Medium[2]	Near-term	Recommended in IRRP. Subject to the plans and timelines for connection of a new Geraldton mine.
5		Upgrade of other sections of transmission line A4L	Medium[2]	Mid-term	Recommended in IRRP. Subject to the plans and timelines for connection of a new Beardmore mine.
6	Capacity for Pipeline Project and Ring of Fire	A 230 kV transmission line from Nipigon or Terrace Bay to Geraldton, and voltage support devices	High[2]	Mid/Long-term	Recommended in IRRP. Subject to the plans and timelines for connection of pipeline loads and mines.
7		A 115 kV transmission line from Manitouwadge to Geraldton, and voltage support devices	High[2]	Long-term	Recommended in IRRP. Subject to the plans and timelines for connection of additional pipeline loads.

[1] The Medium growth scenario for North-of-Dryden sub-region corresponds to the "Reference Scenario" in the IRRP

[2] The Low growth scenario for Greenstone-Marathon sub-region corresponds to scenario "A" of the three sub-systems in the IRRP, the Medium growth scenario corresponds to scenario "B" of Greenstone and Marathon and scenario A of Northshore sub-systems in the IRRP, and the High growth scenario corresponds to scenario "D" of Greenstone, scenario "C" of Marathon and scenario "A" of Northshore sub-systems in the IRRP (see section 5 for details of Load Forecast Scenarios).

West of Thunder Bay Sub-Region Wires Plans					
No.	Need	Wires Options	Load Growth	Term	Status
8	Dryden 115 kV System Capacity	A 230/115 kV auto-transformer in Dryden area	High	Mid-term	Proposed in IRRP. Next planning cycle will reassess the need.

Thunder Bay Sub-Region Wires Plans					
No.	Need	Wires Options	Load Growth	Term	Status
9	Thunder Bay 115 kV System Capacity	A 230/115 kV auto-transformer in Thunder Bay area	High	Long-term	Proposed in IRRP. Next planning cycle will reassess the need.
10	Port Arthur TS Transformation Capacity	Upgrade of Low-Voltage equipment at Port Arthur TS	All Scenarios	Long-term	Proposed in IRRP. LV equipment are planned for End-of-Life replacement in mid-term. Next planning cycle will reassess the need.

The IRRP for Thunder Bay sub-region identified a near-term need for upgrading the thermal rating of circuit R2LB between Lakehead TS and Birch TS to that of the companion circuit R1LB. This upgrade has been completed in Q4 2016.

Most of the above plans are highly dependent on the needs of industrial customers in the region. Proceeding to the Development phase for the customer-driven projects requires request by, and agreement with, the customer(s). Currently, only Project No. 1 has proceeded to the Development phase. The only supply point in the region which is presently at its load-meeting capability limit is Pickle Lake and Project No. 1 will address the need at this location.

Additionally, the IESO Draft Remote Community Connection Plan report [6] has recommended the connection of 21 First Nations communities in the northern part of the region to the electricity grid. An Order in Council from the government, dated July 20, 2016, has directed the OEB to amend Wataynikaneyap Power LP's transmitter licence to develop and seek approvals for the connection of sixteen remote communities and the Dryden-Pickle Lake transmission line, i.e. Project No. 1 identified above.

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. There is adequate time to review the proposed or recommended plans to meet the long-term needs and develop preferred alternatives in the next planning cycle. Should there be a need that emerges prior to the next planning cycle such as but not limited to change in load forecast, the regional planning cycle will be started earlier to address the need.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE NORTHWEST ONTARIO REGION.

The report was prepared by Hydro One Networks Inc. - Transmission ("Hydro One") with input and on behalf of the Working Group that consists of Hydro One, Hydro One Networks Inc. - Distribution, the Independent Electricity System Operator ("IESO"), Atikokan Hydro Inc., Kenora Hydro Electric Corporation Ltd., Thunder Bay Hydro Electricity Distribution Inc., Sioux Lookout Hydro Inc. and Fort Frances Power Corporation in accordance with the Regional Planning process established by the Ontario Energy Board in 2013.

Northwest Ontario region is divided into 4 sub-regions: City of Thunder Bay, West of Thunder Bay, North of Dryden, and Greenstone-Marathon. The IESO has also assessed the economic case for connecting the Remote Communities north of Red Lake and Pickle Lake to the provincial grid. Electrical supply to the Region is provided by fifty two 230kV and 115kV transmission and distribution stations. Some of the stations are shown in Figure 1-1.

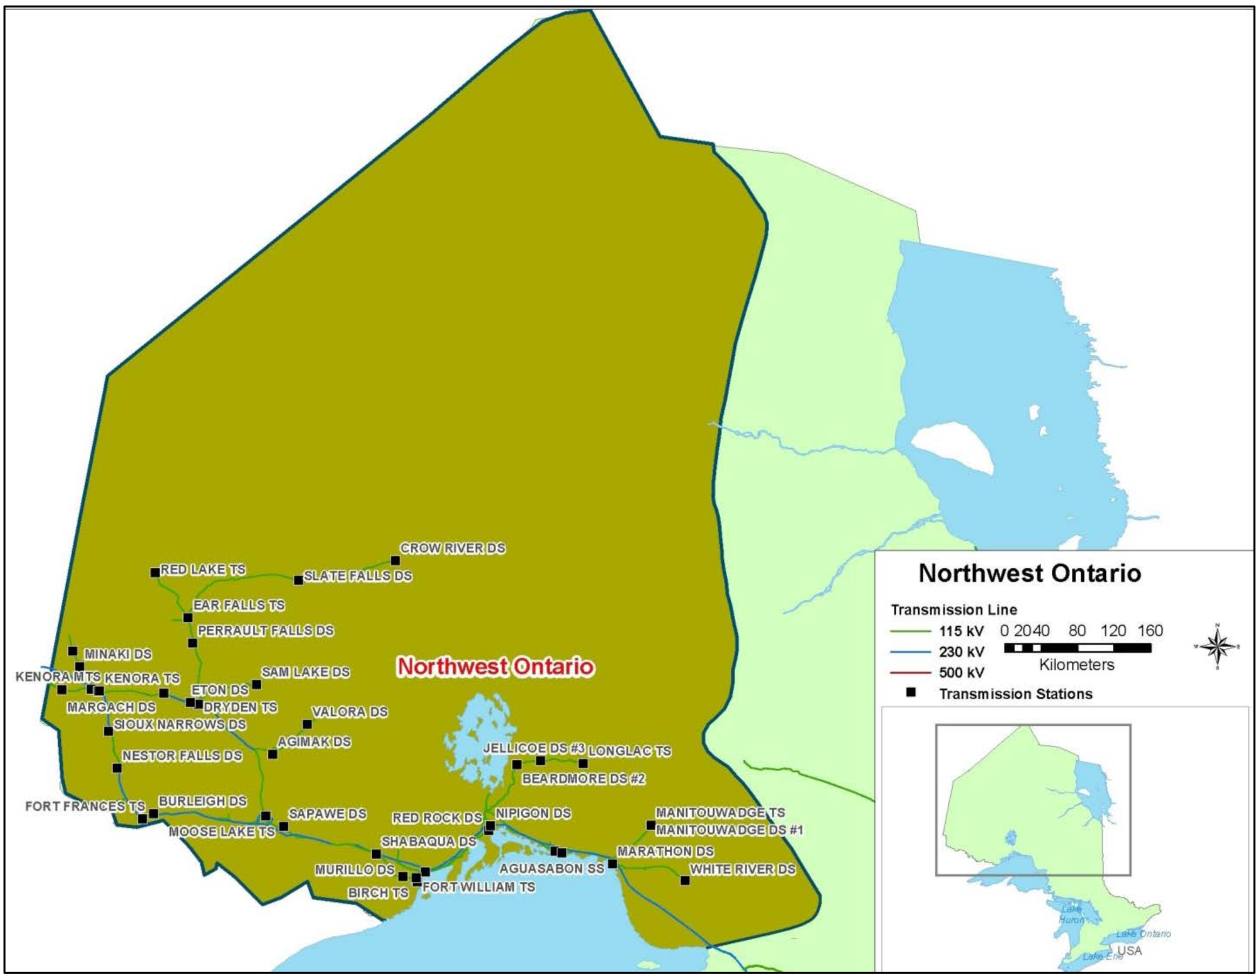

Figure 1-1 Map of Northwest Ontario Region

13

1.1 Scope and Objectives

This RIP report examines the needs in the Northwest Ontario Region. Its objectives are to:

- Review of needs (near and medium-term) identified through the IRRP process.
- Develop a wires plan to address all needs where wires solution is the most appropriate.
- Discuss long-term needs identified during the planning process

The RIP reviews factors such as the LDC load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2015-2025 period;
- Develop an approach to address any longer term needs identified by the Working Group.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast used in this assessment;
- Section 6 discusses the needs and provides the alternatives and preferred solutions;
- Section 7 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [3] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address one or more of the needs. If no further regional coordination is required and localized needs cannot be met by non-wires solutions, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and a Local Plan ("LP") is developed to address localized needs. Ultimately, local plans are also incorporated into the RIP report.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions and/or different needs.

The IRRP phase will generally assess integrated alternatives consisting of infrastructure (wires) and/or resource (CDM and Distributed Generation). Detailed information regarding wires options may not be available or necessary within the scope of the IRRP. The level of detail for wires options as part of the IRRP will be to a level which is sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and refine the assessment of specific wires alternatives, and recommend a preferred

[3] Also referred to as Needs Screening.

wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and may establish Local Advisory Committees (LAC) in the region or sub-region. For the Northwest Ontario Region, community engagement through a number of LACs is on-going.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

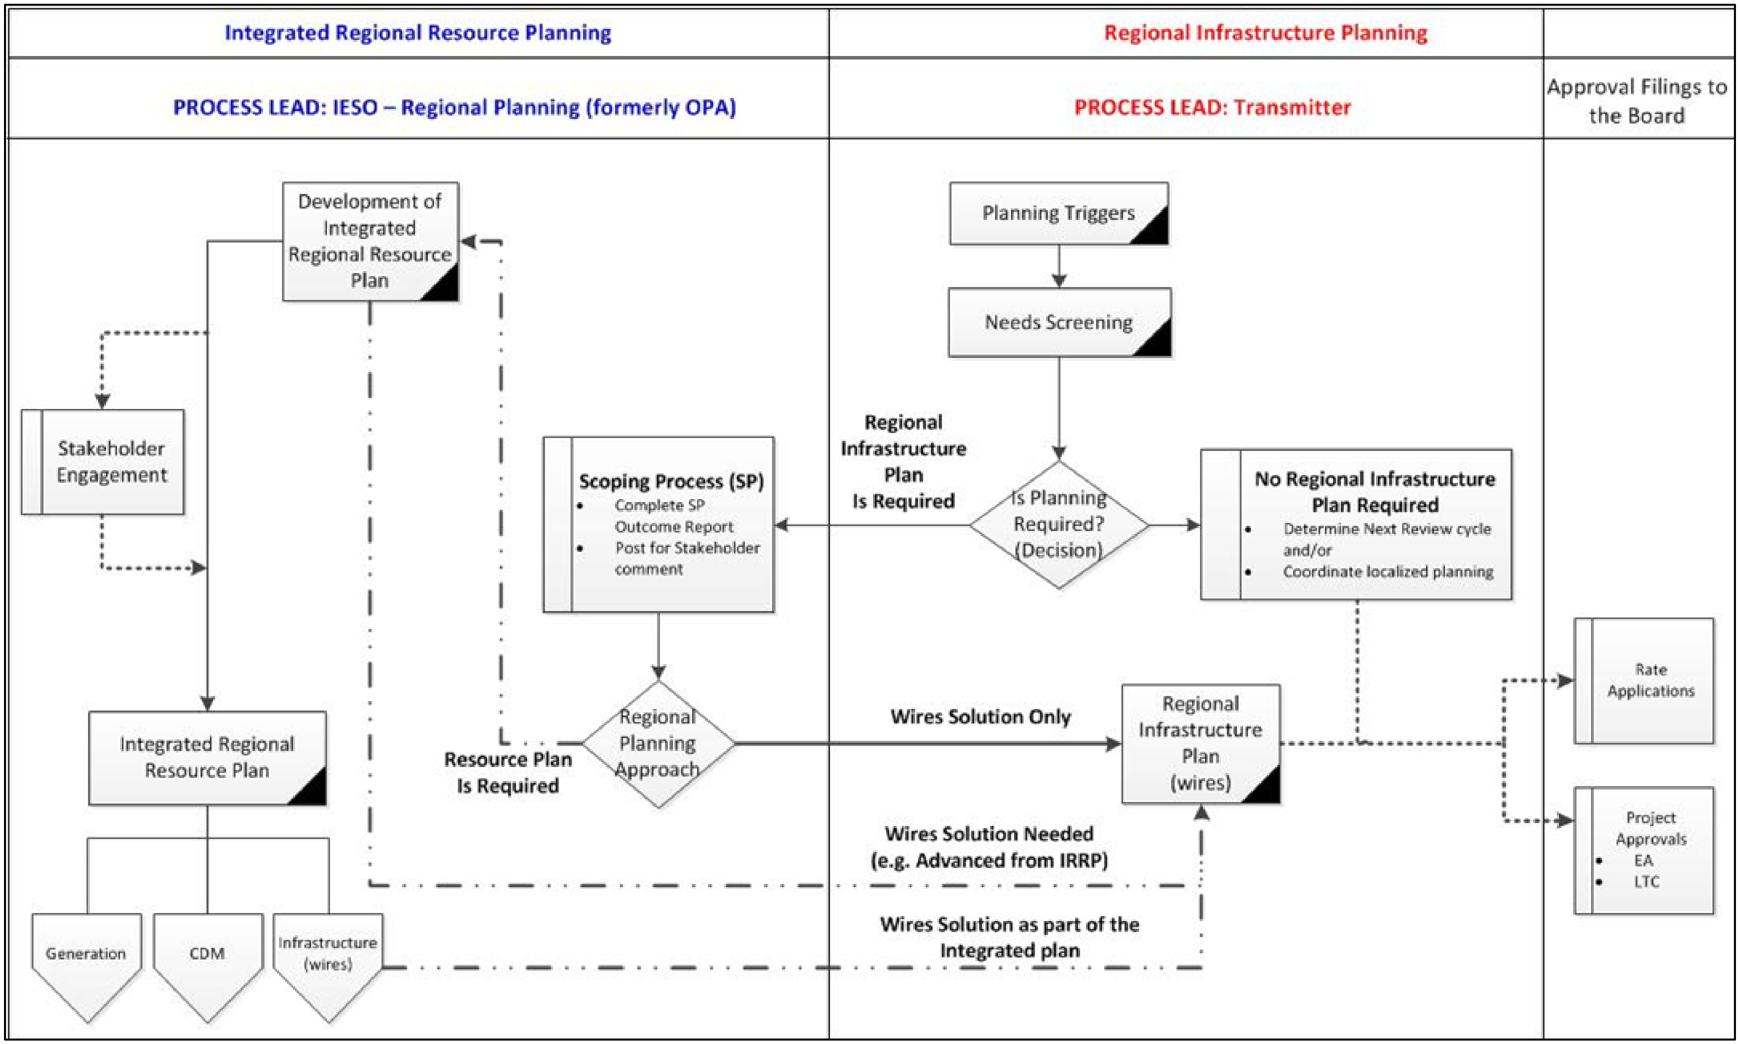

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1) Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

The extent and scope of each step naturally depends on the outcome of the previous step. The outcome of the previous stage of the regional planning process, i.e., IRRP, also influences the scope of Step 2 to a large extent.

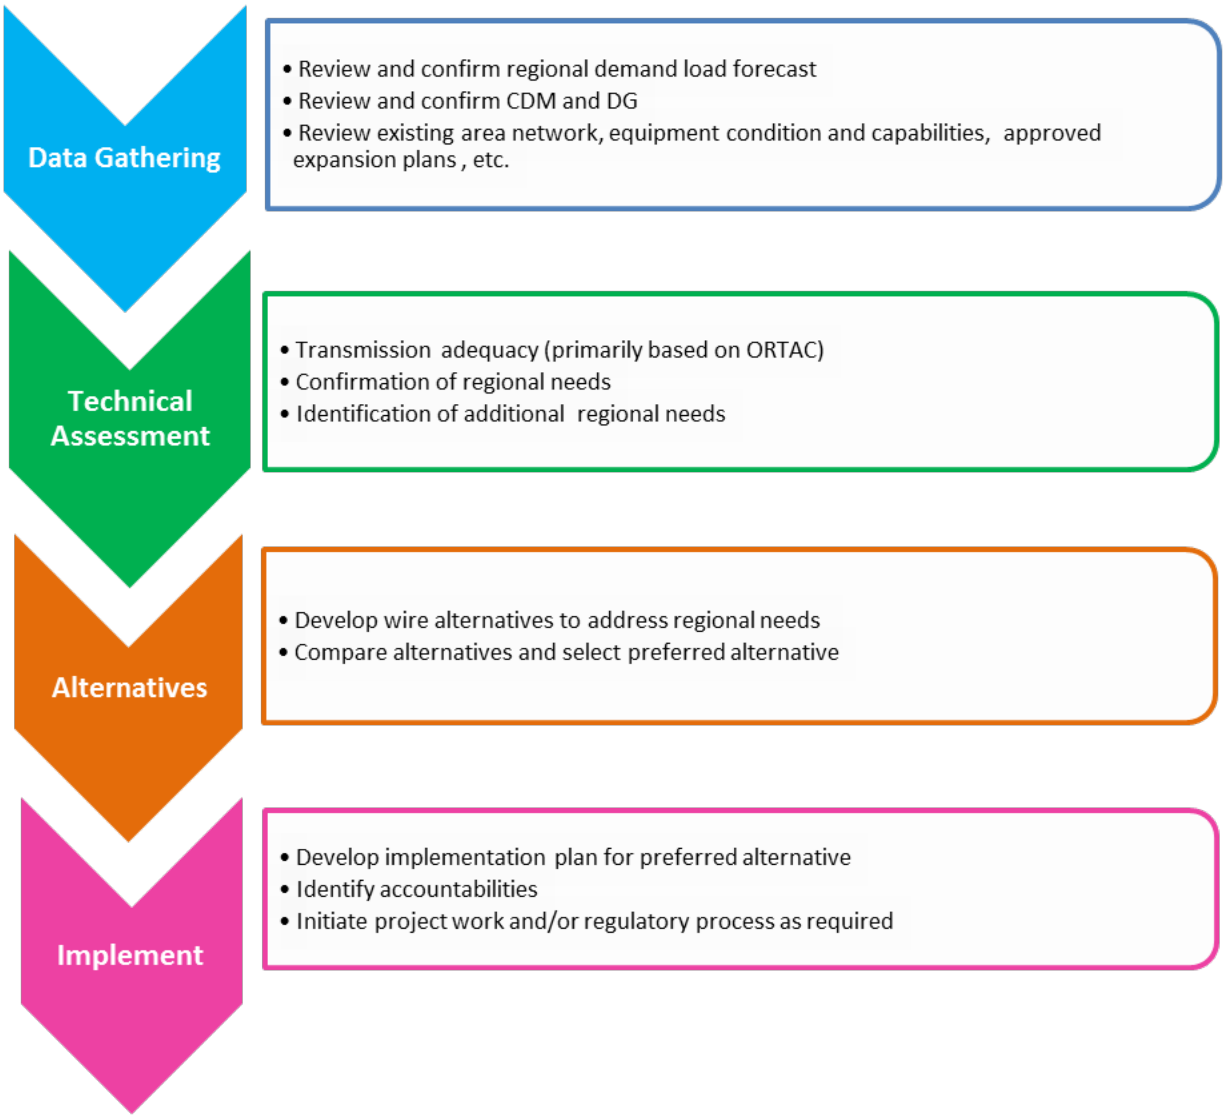

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

NORTHWEST ONTARIO REGION IS ROUGHLY BORDERED BY WEST OF HUDSON BAY AND JAMES BAY, NORTH AND WEST OF THE LAKE SUPERIOR, AND EAST OF THE CANADIAN PROVINCE OF MANITOBA. THE REGION CONSISTS OF THE DISTRICTS OF THUNDER BAY, KENORA AND RAINY RIVER. ALMOST 54 PERCENT OF REGION'S ENTIRE POPULATION LIVES IN THUNDER BAY. THE REGION ACCOUNTS FOR APPROXIMATELY 60 PERCENT OF LAND AREA OF THE PROVINCE AND ABOUT TWO PERCENT OF ONTARIO'S TOTAL POPULATION.

Bulk electrical supply to the Northwest Ontario Region is provided through a combination of local generation stations connected to the 230 kV and 115 kV network, and the East-West Tie transmission corridor.

The Local Distribution Companies ("LDCs") that serve the electricity demands for the Northwest Ontario are Hydro One Networks Inc. (Distribution), Atikokan Hydro Inc., Kenora Hydro Electric Corporation Ltd., Sioux Lookout Hydro Inc., Thunder Bay Hydro Electricity Distribution Inc., and Fort Frances Power Corporation. The LDCs receive power at the step down transformer stations and distribute it to the end users – industrial, commercial and residential customers.

The January 2015 Integrated Regional Integrated Regional Resource Plan ("IRRP") report for North of Dryden Sub-Region, the June 2016 IRRP report for Greenstone-Marathon Sub-Region, the July 2016 IRRP report for West of Thunder Bay Sub-Region, and the December 2016 IRRP report for Thunder Bay Sub-Region focused on northern, eastern, western, and central parts, respectively, of the Region. All IRRP reports were prepared by the IESO in conjunction with Hydro One and the LDC. A map and a single line diagram showing the electrical facilities of the Northwest Ontario Region, consisting of the sub-regions, is shown in Figure 3-1 and Figure 3-2, respectively.

3.1 North of Dryden Sub-Region

A radial single-circuit 115 kV transmission line ("E4D") supplies electricity to the customers in the North of Dryden sub-region from Dryden TS. The major supplying station for this sub-region is Dryden TS, where the voltage is stepped down from the 230 kV to 115 kV, to serve local and industrial customers. Electricity demand in the North of Dryden sub-region is also supplied by local hydroelectric generation.

3.2 Greenstone-Marathon Sub-Region

Electrical supply to the customers in the Greenstone-Marathon Sub-Region comprises of Marathon TS and Alexander Switching Station ("SS"). Located in the town of Marathon, Marathon TS connects the Northwest electrical system to the East Lake Superior electrical system at Wawa TS, with two 230 kV lines - W21M and W22M. Marathon TS steps down 230 kV to 115 kV and supplies customers in the

Town of Marathon, White River and Manitouwadge through a 115 kV single circuit - M2W. Three circuits A5A, A1B, and T1M - in series connect Marathon TS to Alexander SS.

Alexander SS connects Alexander Generating Station ("GS"), Cameron Falls GS, and Pine Portage GS - to the system. A 115 kV single-circuit A4L, connected to the Alexander SS, supplies electricity to the Municipality of Greenstone and its surrounding areas. Nipigon GS is also connected to the circuit A4L.

3.3 West of Thunder Bay Sub-Region

Supply to this Sub-Region is provided from a 230 kV transmission system consisting of the Kenora TS, Fort Frances TS, Dryden TS, and Mackenzie TS. Kenora TS steps down 230 kV to 115 kV and supplies customers in the City of Kenora and surrounding areas. In addition, it also connects Ontario to Manitoba's electrical system through two 230 kV transmission lines – K21W and K22W. Fort Frances TS steps down 230 kV to 115 kV and supplies customers in the City of Fort Frances and surrounding areas. It also connects Ontario to Minnesota's electrical system through a 115 kV transmission line – F3M. Dryden TS steps down 230 kV to 115 kV and supplies customers in the City of Dryden and surrounding areas. It also connects West of Thunder Bay to North of Dryden Sub-Region. Mackenzie TS steps down 230 kV to 115 kV and supplies customers in Atikokan and surrounding areas. It also connects West of Thunder Bay to the Thunder Bay Sub-Region. The West of Thunder Bay Sub-Region is also supplied by many local hydroelectric generation facilities

3.4 Thunder Bay Sub-Region

Thunder Bay Sub-Region consists of the Lakehead TS as the 230 kV step-down transformation facility which steps down 230 kV to 115 kV and supplies customers in the City of Thunder Bay and surrounding areas. The area is served primarily at 115 kV by three step-down transformer stations - Birch TS, Fort William TS, and Port Arthur TS #1.

Please see Figure 3-1 and 3-2 for a map and single line diagram of the Sub-Region facilities.

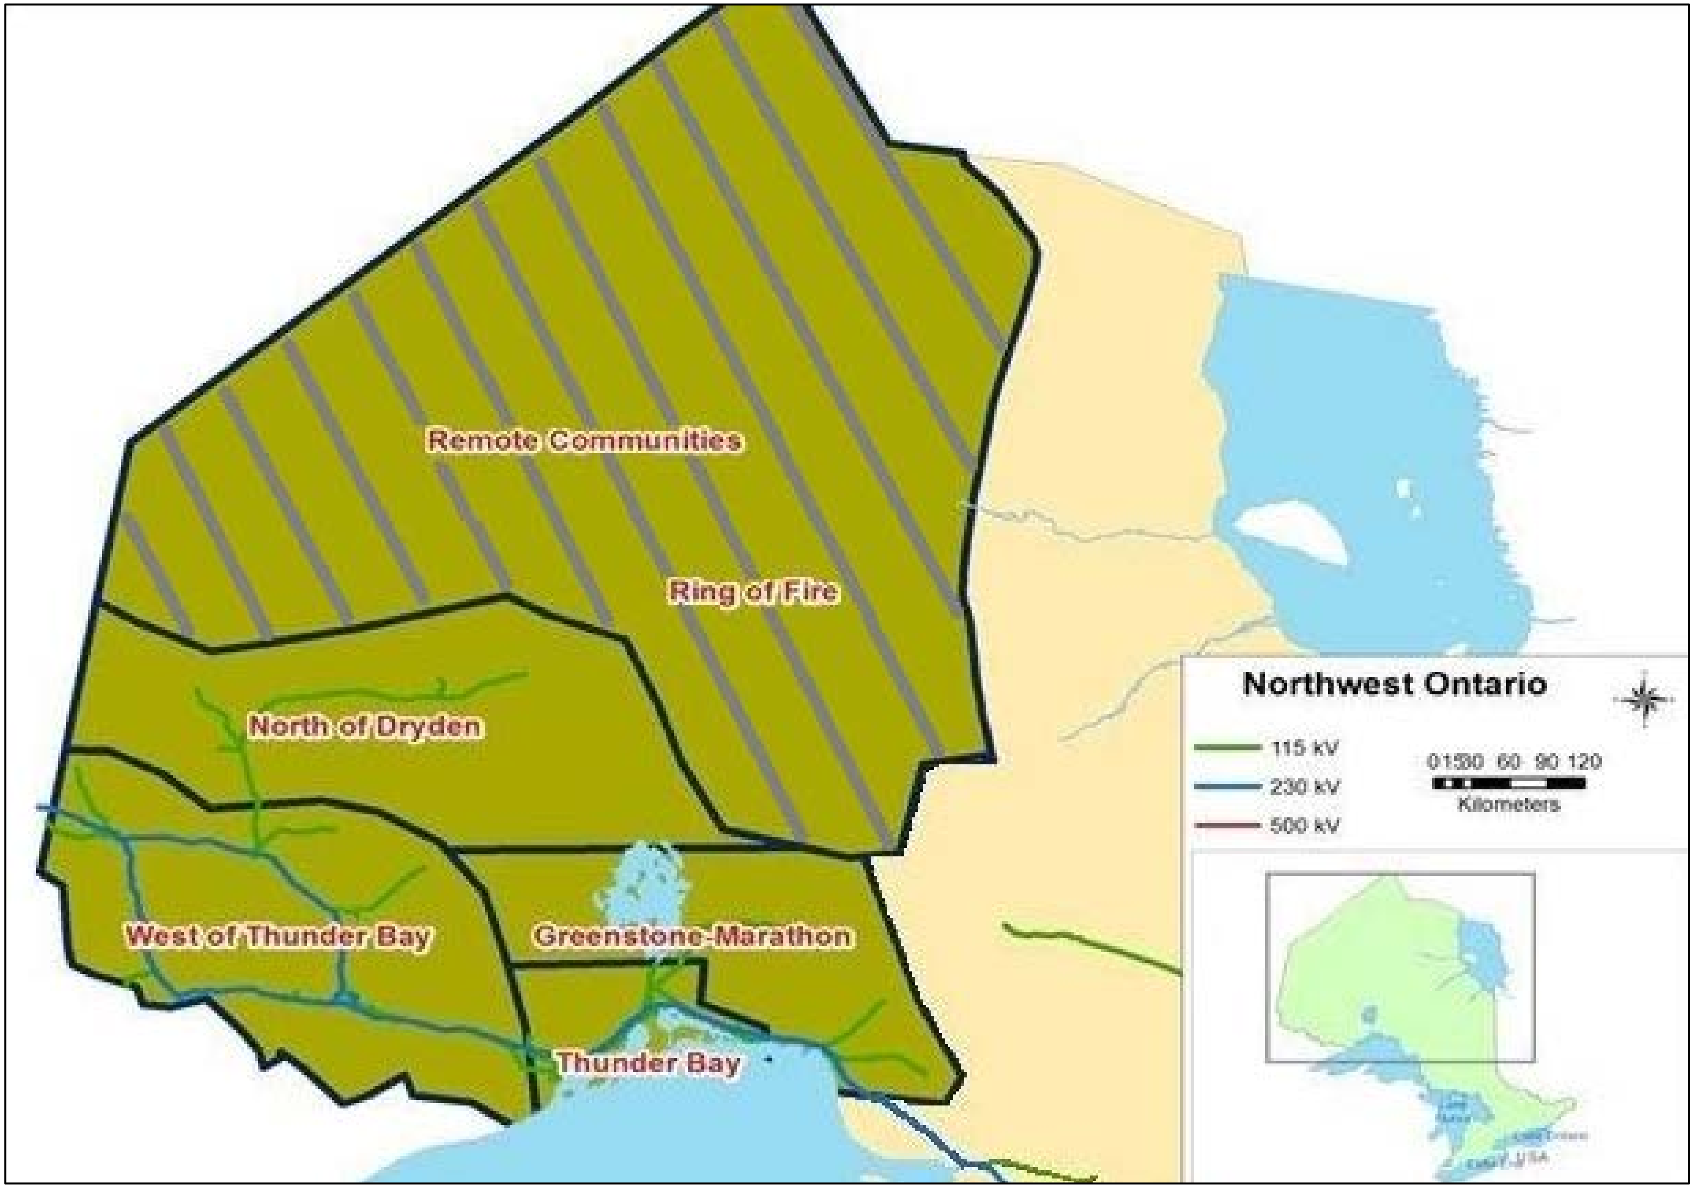

Figure 3-1 Northwest Ontario Region – Supply Areas

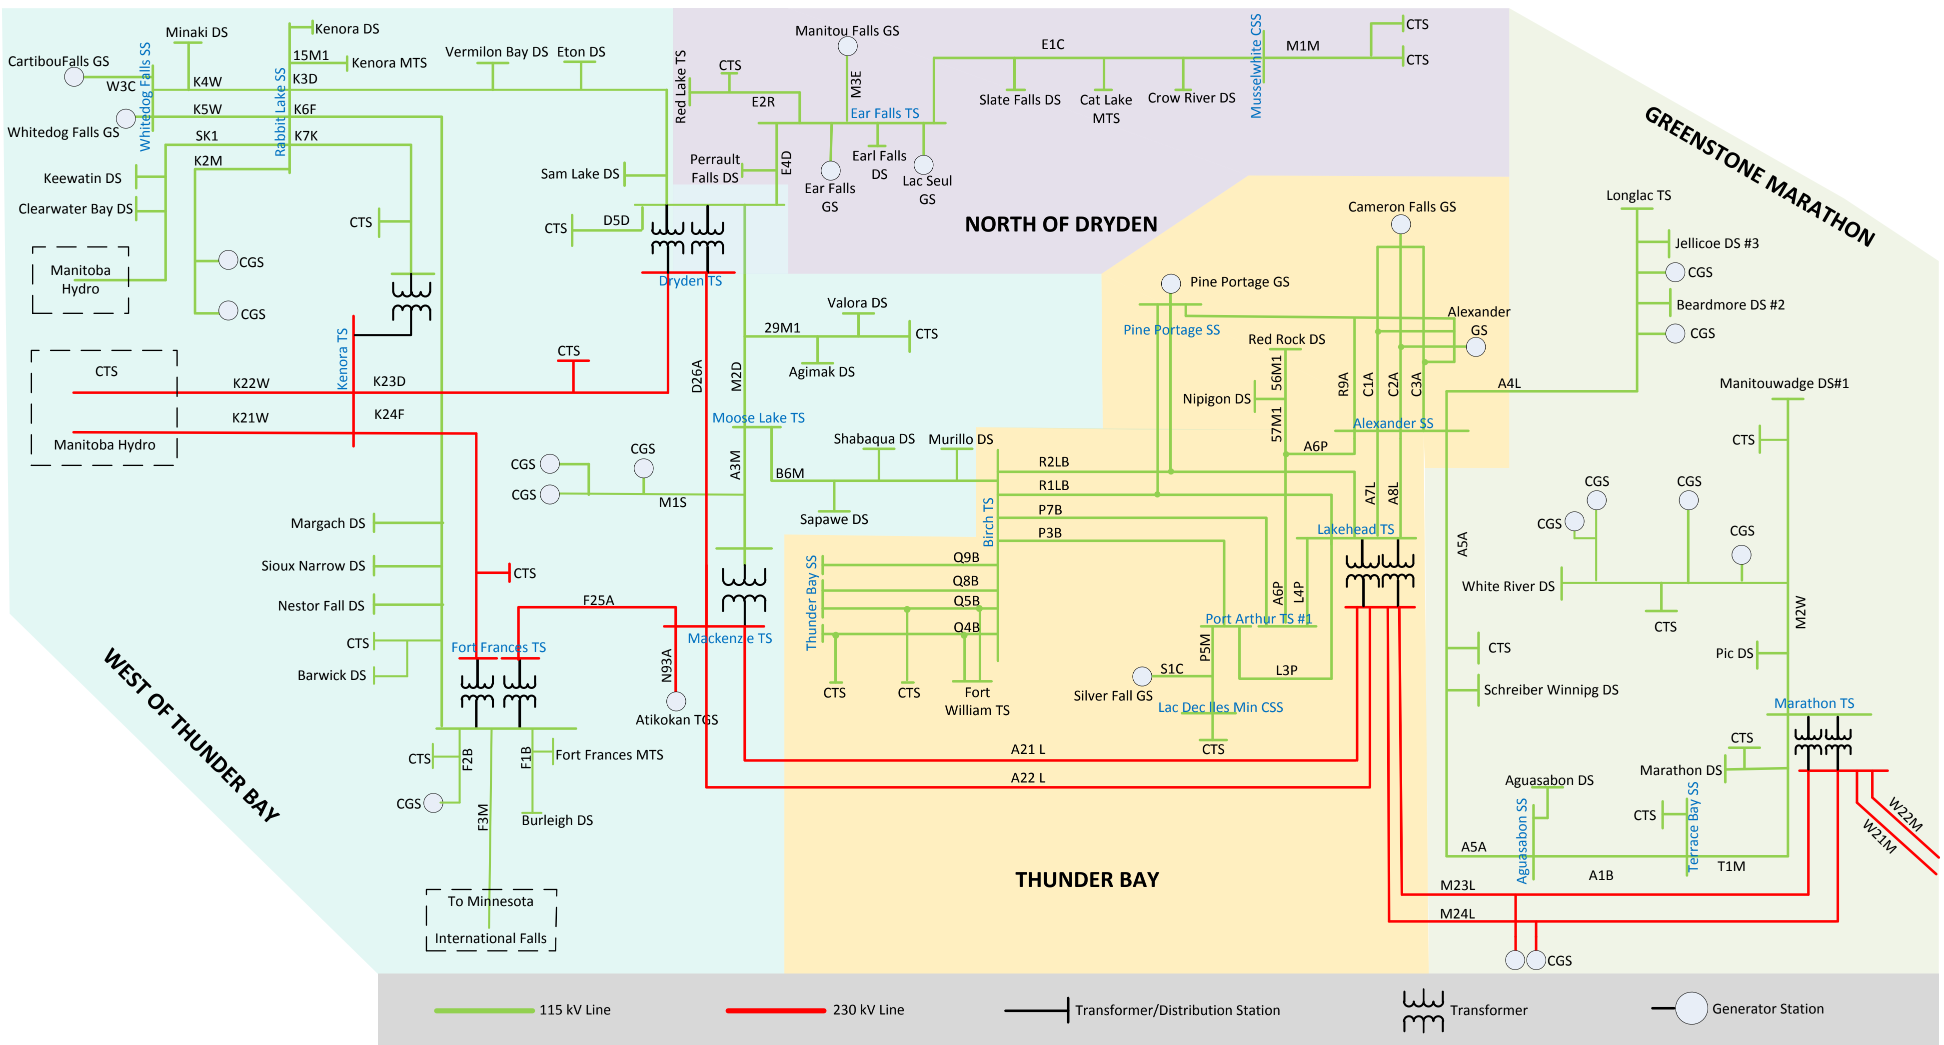

Figure 3-2 Northwest Ontario Region – Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED OVER THE LAST TEN YEARS AND PLANNED FOR NEAR FUTURE

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED BY HYDRO ONE, ARE UNDERWAY, OR ARE PLANNED FOR THE COMING YEARS, AIMED AT IMPROVING THE SUPPLY TO THE NORTHWEST ONTARIO REGION IN GENERAL.

This section describes the completed development and sustainment projects in the region, as well as the sustainment projects that are in the execution stage or planned for the coming years.

4.1 Past Major Projects

In the past 10 years, the following are some of the major projects completed in the Northwest Ontario Region.

1. **Barwick TS** –Barwick TS was built in the second and third quarter of 2013 to replace load-serving facilities at Fort Frances TS as majority of these assets were reaching the end of their useful life. The new facilities include: two 42 MVA 115/44 kV transformers and the associated breakers, switches, surge arresters, etc. and two cap banks, each rated 4.9 MVAR at 44 kV, and the associated breakers and switches.

2. **Birch TS –** One of three 42 MVA step down transformers (115/25 kV) at Birch TS was replaced in December 2015.

3. **Dryden TS** – In addition to replacing 5 HV breakers, 2 LV breakers and 12 switches between 2014-2016, 2x40 MVAR Shunt reactors at Dryden TS were installed in Q3 2014.

4. **Fort Frances** – In addition to replacing 2 LV breakers and 8 switches (2010-2016), 21.6 MVAR/13.8 kV capacitor bank was installed at Fort Frances in November 2010.

5. **Kenora TS** – 1 LV breaker and 4 switches were replaced between 2009 and 2015.

6. **Lakehead TS** – 3 HV breakers, 1 LV breaker, 5 switches, and 1 autotransformer (230/13.9 kV) were replaced between 2009 and 2016 as part of the sustainment work. In addition, one synchronous condenser at Lakehead TS was replaced by a +60/-40 MVAR SVC in December 2009.

7. **Longlac TS** –Transformers T2 and T3 were replaced with two 42 MVA 115/44 kV transformers and associated equipment protections i.e. breakers, switches, surge arresters, etc. In addition, four capacitor banks; each rated at 4.9 MVAR at 44 kV with associated breaker and switches were installed. This work was completed mid-2011.

8. **Manitouwadge TS** – 1 LV breaker, 1 switch, and 1 step down transformer (115/44 kV) were replaced in July 2016.

9. **Marathon TS** – In addition to replacing 1 HV breaker, 2 LV breakers, and 4 switches between 2009 and 2016, 2x40 MVAR shunt reactors were installed in December 2013 and March 2014.

10. **Moose Lake TS** – 5 HV breakers were replaced in 2014.

11. **Port Arthur TS #1** – 10 switches were replaced between 2009 and 2015. In addition, 2x0.5 ohms LV current limiting reactors were replaced with 2x1 ohm reactor. Work was completed in December 2014.

12. **Rabbit Lake SS** – 2 HV breakers and 4 switches were replaced between 2011 and 2016.

13. **Red Lake TS** –Five capacitor banks were upgraded by 2.5 MVAR each to 7.4 MVAR (at 44 kV). This work also included upgrading associated breakers and switches and was completed between December 2015 and July 2016.

4.2 Current or Planned Major Sustainment Projects

The following major sustainment projects are currently under execution or planned for the coming years. These projects are based on the assessment of end of life issues of the aging station's equipment and replacing those that represent risk to the security of the bulk transmission system and reliability for connected customers.

1. **Dryden TS**– is located in the city of Dryden and supplies majority of the customers in the area. It consists of three 115/44 kV power transformers rated at 15MVA each, which are non-standard units and are about 69 years old.

   Hydro One has planned to replace the three EOL transformers with two new standard-size transformers, rated at 42MVA each. The scope of work also includes the replacement of other deteriorating infrastructure, such as LV switchyard (which will be built to current standard), 115 kV OCBs, and select switches.

   This project is currently planned to be completed in 2018.

2. **Ear Falls TS** – supplies customers in the city of Ear Falls in the North of Dryden Sub-Region, through a single transformer T5 (115/44 kV, 19 MVA), backed-up by a spare transformer T5SP (115/44 kV, 8 MVA). The 44 kV LV voltage is further stepped-down to 12.5 kV through Ear Falls DS transformer T1 (44/12.5 kV). Ear Falls TS transformers T5 and T5SP are approximately 47 and 69 years old, respectively, while Ear Falls DS T1 is currently 49 years old.

   Hydro One has planned to eliminate the need for 44 kV to 12.5 kV conversion at Ear Falls DS by replacing T5 and T5SP transformers with 115/13.2 kV transformer units (rated at 12.5 MVA each). The scope of work also involves replacing 44kV equipment with 13.2 kV, replacing 115 kV circuit breakers, and replacing EOL protections, controls, and telecom in new relay building to ensure the integrity of power system protection is maintained.

   This project is currently planned to be completed in 2018.

3. **Alexander SS** – is a 115 kV switching station located in the Thunder Bay Sub-Region and was originally built in 1955. The station terminates five 115 kV circuits for the supply of customers in the area and connects 161 MW of generation from the Nipigon River and Cameron Falls. It consists of ten 115 kV breakers, nine of which are non-standard.

Hydro One has planned to replace all non-standard and EOL equipment at the station. The scope of work involves replacing 115 kV oil circuit breakers with new SF6 breakers, replacing select switches, upgrade of all protection & control facilities and AC station service system.

This project is currently planned to be completed in 2019.

4. **Birch TS** – is a 115 kV transmission station located in City of Thunder Bay in the Thunder Bay Sub-Region and was put in-service in 1955. Birch TS is comprised of a DESN station which supplies local load in the port area of Thunder Bay, as well as being a 115 kV bulk station with 9 lines and the three DESN transformers connected to it.

   Due to the criticality of the station to both transmission and distribution systems, protection and control equipment that is presently located in the basement will be relocated to a new relay building. The scope of work involves replacing 115 kV circuit breakers and 25 kV capacitor banks, and replacing/relocating end of life protections in the new relay building.

   This project is currently planned to be completed in 2019.

5. **Pine Portage SS** – is a 115 kV switching station located in the Greenstone-Marathon Sub-Region and was put in-service in 1954. The switching station has three outgoing 115 kV transmission lines connecting to Lakehead TS, Birch TS and Alexander SS. Pine Portage GS is also connected to this switching station.

   Hydro One has planned to replace all end of life equipment at the station. The scope of work involves replacing five 115 kV oil circuit breakers with new 2000A SF6 breakers, associated disconnect switches, protection, control and teleprotection facilities.

   This project is currently planned to be completed in 2020-2023.

6. **Aguasabon SS** – is a 115 kV switching station in Greenstone-Marathon Sub-Region and was put in-service in 1948. The station has two transmission lines connecting to Alexander SS and Terrace Bay SS. The station is also critical to the connection of Aguasabon DS.

   Hydro One has planned to replace the EOL equipment at the station. The scope of work involves replacing/upgrading AC/DC station service, and replacing equipment protections.

   This project is currently planned to be completed in 2021-2024.

7. **Port Arthur TS #1** – Port Arthur TS #1 is a 115/25 kV station located in the Thunder Bay Sub-Region and was put in-service in 1950.

   Hydro One has planned to replace all end of life equipment at the station. The scope of work involves replacing AC/DC station service systems, 25kV switchyard and associated protection equipment in the new building, and 115 kV associated protection equipment in the existing building

   This project is currently planned to be completed in 2021-2024.

8. **Rabbit Lake SS** – is a 115 kV switching station located in the West of Thunder Bay Sub-Region. The switching station has seven 115 kV transmission lines connecting to three customer generating stations (CGSs) as well as Whitedog Falls SS, Kenora TS, Fort Frances TS, Dryden TS, and the interconnection

with Manitoba Hydro. There are six 115 kV oil circuit breakers and two 115 kV SF6 circuit breakers in the yard.

Hydro One has planned to replace the EOL equipment at the station. The scope of work involves replacing EOL 115 kV circuit breakers, select switches, and equipment protections.

This project is currently planned to be completed in 2021-2024.

9. **Terrace Bay SS** – is located in the Greenstone-Marathon Sub-Region and was put in-service in 1973. The switching station has two 115 kV transmission lines connecting to Marathon TS and Aguasabon SS. The station is also critical to the connection of a Customer Transformer Station (CTS).

   Hydro One has planned to replace all end of life equipment at the station. The scope of work involves replacing protections, controls, telecom, select switches, and AC/DC station service system.

   This project work is currently planned to be completed in 2021-2024

10. **Whitedog Falls SS** – is a 115 kV switching station located in the West of Thunder Bay Sub-Region. The switching station has three 115 kV transmission lines, connecting to Rabbit Lake SS, Caribou Falls GS, and Whitedog Falls GS.

    Hydro One has planned to replace the EOL equipment at the station. The scope of work involves replacing 115 kV circuit breakers and select switches. In addition, scope of work includes replacing/upgrading of DC station supply system.

    This project is currently planned to be completed in 2021-2024.

11. **Moose Lake TS** – is a 115/44 kV transformer station built in 1948. It is located on Moose Lake near Atikokan in the West of Thunder Bay Sub-Region. Moose Lake TS consists of two non-standard step-down transformers T2 and T3 rated at 8MVA and 15MVA, respectively. In addition, the two transformers are 69 years old.

    Hydro One has planned to replace the EOL equipment at the station. The scope of work involves replacing the two non-standard power transformers (T2, T3) with standard 110-44 kV, 25/41.7 MVA units, two low voltage oil circuit breakers with new SF6 breakers, and replacing and upgrading the protection, control and AC/DC station service facilities

    This project is currently planned to be completed in 2022-2025

12. **Kenora TS** – is a 230/115 kV station located in the West of Thunder Bay Sub-Region and critical to supply of the city of Kenora and the interconnection with the province of Manitoba.

    Hydro One has planned to replace the EOL equipment at the station. The scope of work involves replacing/upgrading AC/DC station service systems and replacing protection equipment.

    This project is currently planned to be completed in 2024-2027.

13. **Mackenzie TS** – is a 230/115 kV station is located in the West of Thunder Bay Sub-Region. Mackenzie TS has six 230 kV breakers which are about 46 years old.

Hydro One has planned to replace all EOL equipment at the station. The scope of work involves replacing 230 kV circuit breakers, select protections, and AC/DC station service system.

This project is currently planned to be completed in 2024-2027.

14. **Fort Frances TS** – is located in the Town of Fort Frances and was put in-service in 1947.

    Hydro One has planned to replace the EOL equipment at the station. The scope of work involves replacing high voltage circuit breakers, replacing/upgrading AC/DC station service system and protection equipment.

    This project is currently planned to be completed in 2025-2028.

15. **Lakehead TS** – is a 230/115 kV transformer station located in the Thunder Bay Sub-Region and was put in-service in 1955. The station is critical to the transmission system of the Northwest and a major hub for East-West power transfer.

    Hydro One has planned to replace all EOL equipment at the station to ensure reliability of the transmission system and supply to the customers. The scope of work involves replacing high voltage circuit breakers with new SF6 breakers, replacing four LV circuit breakers with new SF6 breakers, replacing protection equipment associated with 115 kV facilities and the synchronous condenser, replacing select switches, and replacing/upgrading AC station service system.

    This project is currently planned to be completed in 2025-2028.

16. **Marathon TS** – is a 230/115 kV transformer station, located in the City of Marathon in the Greenstone-Marathon Sub-Region. It was put in-serviced in 1970. The station is critical to the transmission system of the Northwest and a major hub for East-West power transfer. All four 115 kV oil circuit breakers at the station are about 40 years old. Whereas, three 230 kV circuit breaker at the station are about 48 years old.

    Hydro One has planned to replace all EOL equipment at the station to ensure reliability of the transmission system and supply to customers. The scope of work involves replacing three EOL 230 kV circuit breakers with new SF6 breakers, and four EOL 115 kV circuit breakers with new SF6 breakers. In addition, the scope of work also includes replacing disconnect switches, protection equipment, and AC station service system.

    This project is currently planned to be completed in 2025-2028.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast Scenarios

For the purpose of this RIP, the LDCs reviewed their load forecasts and confirmed that they have not changed significantly from the load forecasts reported in the Northwest IRRPs. Based on the load forecasts from the LDCs and the industrial (mining) load forecasts of the Northwest IRRPs, three scenarios of future demand has been considered for each Northwest sub-region in this RIP. Table 5-1, Table 5-2, Table 5-3, and Table 5-4 show the forecasted load for the Low, Medium and High growth scenarios.

5.2 Other Study Assumptions

The other assumptions made in this RIP report include,

- The study period is 2016-2025.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be available by the specified in-service dates.
- Since in the Northwest region winter peak is more critical than the summer peak, the study is based on winter peak conditions.

6. SUMMARY OF REGIONAL NEEDS AND PLANS

THIS SECTION DISCUSSES THE WIRE NEEDS FOR THE NORTHWEST ONTARIO REGION AND SUMMARIZES THE RECOMMENDED WIRES PLANS FOR ADDRESSING THE NEEDS.

This section provides a summary of the needs and plans for the four Northwest sub-regions. The load forecasts from the LDCs have not materially changed since the completion of the previous phase (IRRP) of Regional Planning for the Northwest. Therefore, the assumptions and load growth scenario for industrial loads, as well as the needs and plans identified in this RIP are consistent with the Northwest IRRPs. The needs and recommended plans in the region are largely driven by the industrial load growth, particularly the mining sector. Proceeding to the Development phase of the customer-driven projects requires formal request by the customers and commercial agreements between Hydro One and the customers.

6.1 North of Dryden Sub-Region

Most of the demand in the North of Dryden sub-region is from the mining sector. The demand growth is driven by the expansion of this sector, as well as the connection of up to 21 remote communities in the northern parts of the region to Red Lake and Pickle Lake and growth in the mining sector, including potential developments in the Ring of Fire which may be supplied from Pickle Lake.

The North of Dryden IRRP [2] for this sub-region has assumed Low, Medium (referred to as Reference in IRRP [2]) and High load growth scenarios. Based on these scenarios, it has identified the needs and recommended wires plans in near-term, mid-term and long-term. The following are summaries of the needs and recommended plans for this sub-region, which consists of Pickle Lake sub-system, Red Lake sub-system, and Ring of Fire sub-system.

6.1.1 Pickle Lake Needs and Recommended Plans

The North of Dryden IRRP [2] has identified that the existing single supply to Pickle Lake, i.e. the 115 kV circuit E1C, is serving 24 MW of load and is at its capacity. Any load growth in the near-term from the existing mine or connection of remote communities will require increase of LMC. The additional capacity needs, based on the medium (reference) load growth scenario are 18 MW, 28 MW and 47 MW in near-term, mid-term and long-term, respectively.

Pickle Lake LMC is limited by voltage stability. Providing dynamic voltage support, e.g. installing Static VAR Compensator (SVC) at Pickle Lake offers moderate increase in LMC, assuming the remaining capacity of circuit E4D will be available for this load increase. One alternative assessed in the IRRP is to install a new 115 kV single-circuit line from Valora, south of Dryden, to Pickle Lake to provide additional LMC that meets the near-term needs of Pickle Lake and releases some capacity on circuit E4D. However, in the long-term, with the development of new mines and potential for connection of the Ring of Fire to Pickle Lake (one the alternatives identified in the IRRP), an increase of over 130 MW in LMC may be required under the high growth forecast. As a result, the recommendation is to proceed with a plan required to meet the needs of the medium (reference) and high growth scenarios in the long-term. This plan can make the full capacity of circuit E4D available to serve the Red Lake sub-system.

<u>Recommended Plan:</u>

- Install a new 230 kV transmission line to Pickle Lake from either the Dryden area (e.g. Dinorwic) or Ignace area;

- Install a new 230 kV switching station to connect the new line to the existing circuits D26A;
- Install a new 230/115 kV auto-transformer at the end of the new line in Pickle Lake;
- Install new 115 kV switching facilities (circuit breakers) to connect the existing circuit E1C, existing customers at Pickle Lake and the new connections of the remote communities to the new auto-transformer; and
- Install required reactive compensation for voltage control

An Order in Council from the government, dated July 20, 2016, has directed the OEB to amend Wataynikaneyap Power LP's (Wataý Power) licence for Wataý Power to develop and seek approvals for the Line to Pickle Lake and the connection of sixteen remote communities. Wataý Power has initiated the Development phase of the project for these connections. Currently the planned in-service date of the 230 kV line to Pickle Lake is Q2 2020, based on Wataý Power's active connection assessment with the IESO.

6.1.2 Red Lake Needs and Recommended Plans

The North of Dryden IRRP [2] has identified that the current LMC of 61 MW at Red Lake, supplied by circuits E2R and E4D, is insufficient to meet the needs of the mining load, based on the expected growth at this location, even in near-term. The additional capacity needs, based on the medium (reference) load growth scenario are 30 MW, 44 MW and 48 MW in near-term, mid-term and long-term, respectively. Additional capacity needs increase to 75 MW under high load growth scenario.

The wires plans to meet the near-term needs are the following.

Recommended Plan:

- Upgrade circuit E4D to a summer rating of 660 A
- Upgrade circuit E2R to a summer rating of 610 A
- Provide additional voltage control at Ear Falls and/or Red Lake

However, since the load increase in the mining sector has not materialized at the same pace as previously anticipated, the initial plans for the upgrade of circuits E4D and E2R have been put on hold, awaiting customer request. A recent System Impact Assessment by the IESO for a load increase at Red Lake has determined that although the existing system can meet the demand, circuit E4D is reaching its thermal limit. Therefore, the above plan for the upgrade of circuit E4D (and E2R) can proceed in case of a request by, and agreement with, customers for additional load. Alternatively, operating measures can be used until additional firm capacity becomes available in the mid-term.

In the mid/long-term, assuming that the planned 230 kV line to Pickle Lake (see the previous section) is completed, which can make the full capacity of circuit E4D available to serve the Red Lake sub-system, there will be sufficient capacity to meet the needs under medium (reference) and high load growth scenarios. Only if the needs exceed the high growth forecast of this planning horizon, or the planned 230 kV line to Pickle Lake is not completed, a new 115 kV or 230 kV line from Dryden to Ear Falls will be one of the alternatives for meeting the demand.

6.1.3 Ring of Fire Sub-system Needs and Potential Options

The North of Dryden IRRP [2] has indicated that as the Ring of Fire sub-system is remote from the existing transmission system, any additional capacity needs would require new facilities. The IRRP has also indicated that transmission supply is the most economic option under all of the forecast scenarios, which considers the five remote communities in the vicinity of the Ring of Fire that have been identified as being economic to connect in the IESO's Remote Community Connection Plan [6] as well as possible mining customers. If mining load does not fully materialize, the North of Dryden IRRP [2] concluded that an east-west supply from the Pickle Lake area was the most economic option. If mining load fully materializes, the IRRP concluded that the economic option is either an east-west supply from the Pickle Lake area or a north-south supply from a point along the East-West Tie. Development in the area is still at an early stage and no firm recommendations can be made at this time.

6.2 Greenstone-Marathon Sub-Region:

The identified needs and recommended wire plans for this sub-region are directly related to a few large industrial developments. Based on the current load meeting capability (LMC) of the sub-region, all circuits except circuit A4L in Greenstone-Marathon sub-region are adequate to meet the projected demand forecast under all scenarios during the planning cycle. Circuit A4L is also adequate under the low demand scenario. The IRRP report [3] has recommended near term (present-5 years), medium term (5-10 years) and long term (10-20 years) actions to address the A4L limitations under the medium and high demand scenarios as described below.

6.2.1 Low Scenario Needs and Recommended Plans

Consistent with the Greenstone-Marathon IRRP, Low Scenario assumptions are as follows:

- Hydro One Distribution customer growth
- Two saw mill re-starts

The existing circuits have sufficient LMC to meet Low Scenario's forecasted demand.

No wire plans are required for this scenario.

6.2.2 Medium Scenario Needs and Recommended Plans

Consistent with the Greenstone-Marathon IRRP, Medium Scenario assumptions are as follows:

- Low Scenario assumptions
- Development of Geraldton mine
- Development of Beardmore mine
- Life extension of the existing Marathon Area mine

Under this scenario, the needs and recommended wires plans are the following.

Accommodate Geraldton mine – Increase Circuit A4L Capacity:

Single-circuit 115 kV line A4L runs from Alexander SS to Longlac TS. A mining development in Geraldton area, with the proposed in-service date of 2019, would increase the near-term demand on circuit A4L to 51 MW, which is higher than its current LMC of approximately 25 MW. The LMC of circuit A4L is limited by voltage.

A major deciding factor in the recommendation for meeting the forecasted demand is the lead time relative to the proposed timelines for the mine development.

<u>Recommended Plan:</u>

If the proposed in service date of 2019 does not change, Installing Reactive Compensation and gas-fired generation in the near term is the recommended solution.

Installing reactive compensation of about +40 MVARs in the form of either synchronous condenser or Static Synchronous Compensators (STATCOM) at the Geraldton mine site would increase the LMC of circuit A4L to 45 MW, making full thermal capability of the circuit available. This form of Reactive Compensation is recommended considering the low short-circuit level at the end of circuit A4L relative to the requirements of the mine. The remaining short fall of approximately 6 MW to meet the needs of the mine can be provided by a customer-based grid-connected gas-fired generation plant with sufficient redundancy, for example, installing two 10 MW gas-fired units.

If the in-service date of the mine is delayed, replacing a section of circuit A4L, between Nipigon and Longlac, along with the installation of the above reactive compensation, would increase the LMC of circuit A4L to about 60 MW. Replacing the section of circuit A4L has a lead time of approximately five years.

Accommodate Beardmore mine – Increase Circuit A4L Capacity

A potential gold mine near Beardmore may be operational within the medium term. If Geraldton mine doesn't connect to circuit A4L as described above, the existing system would be sufficient to support the Beardmore mine.

If the Geraldton mine connects to circuit A4L and the plans for the high-demand scenario (described below) do not proceed, in order to accommodate the Beardmore mine, additional capacity would be required.

Recommended Plan:

Upgrading a section of circuit A4L from Alexander SS to Beardmore Junction is a medium term wires option for supplying the potential mine.

6.2.3 High Scenario Needs and Recommended Plans

Consistent with the Greenstone-Marathon IRRP, High Scenario assumptions are as follows

- Medium Scenario assumptions
- Development of the proposed Energy East pipeline
- Development of additional mines in Marathon Area
- Development of Ring of Fire, with connection to the Greenstone area

Under this scenario, the needs and recommended wires plans are the following.

Accommodate Energy East Pipeline and, potentially, the Ring of Fire – Install New Wires:

Potential Energy East load is subjected to customers' request for connection of the pumping stations to the provincial electricity grid. The medium or long term recommended plans for the High Scenario depend on the Energy East plans and timelines for connecting some or all of the pumping stations, in one or two phases.

The Greenstone-Marathon Sub-Region IRRP [3] also indicates that the Ring of Fire could be potentially connected by an east-west corridor to Pickle Lake or by a north-south corridor to the Nipigon or Marathon areas.

Recommended Plan:

According to the IRRP report [3], the preferred option under the High Scenario, with or without the potential connection of the Ring of Fire, is the following wires plan.

- Install a new 230 kV transmission line to Longlac TS from either from the Nipigon area or from the Marathon (or Terrance Bay) area;
- Install a new 230 kV switching station to connect the new line to the existing circuits M23L-M24L;
- Install a new 230/115 kV auto-transformer at Longlac TS;

- Install required reactive compensation for voltage control and short-circuit level requirements at the mine; and
- Install a new 115 kV Line from Longlac TS to Manitouwadge TS to supply all the pumping stations in the area, possibly in the second phase.

Advancing the plan for the new transmission line and transformer, in order to meet the timelines of the Geraldton mine and the Beardemore mine developments, is an alternative to the upgrade of circuit A4L described under the Medium Scenario above. During outages of the new line or transformer, the new mines and industrial loads need to be interrupted to maintain the loading on circuit A4L below its LMC.

The above plan will improve the reliability for the customers served from Longlac TS by maintaining their supply through the new transmission line and transformer during outages of circuit A4L.

6.3 West of Thunder Bay Sub-Region

This sub-region, as described in the IRRP report [4], consists of four main sub-systems, Moose Lake, Fort Frances, Kenora and Dryden. The West of Thunder Bay Sub-Region is also a source of supply to the North of Dryden sub-region (through the Dryden 115 kV system) and therefore the needs and recommendations from the North of Dryden IRRP (described in the previous sections) were considered in the West of Thunder Bay IRRP.

Similar to the other sub-regions described above, because of the uncertainty in the development plans and connection options, the IRRP has considered low, medium (or reference) and high load growth scenarios in the West of Thunder Bay sub-region and has identified near/mid/long-term needs and recommendations for each scenario.

The low load growth scenario has forecasted a peak demand of close to 240 MW in 2017 (with the startup of a new mine near Rainy River) which will remain fairly flat until 2034.

In the medium load growth scenario, involving new mines and industrial load (pumping stations of the pipeline conversion project), the load forecast increases from 252 MW in 2017 to 345 MW in 2034.

In the high load growth scenario, involving additional mines, the load forecast increases from 305 MW in 2017 to 551 MW in 2034.

6.3.1 Dryden Needs and Plans

The Dryden 115 kV sub-system can provide up to 240 MW of continuous supply to the Dryden and North of Dryden Sub-Region. Under the low and medium (reference) load growth scenarios, this LMC is sufficient to meet the demand of this sub-system.

Under the high load growth scenario, additional capacity of 50 MW will be required on the 115 kV system at Dryden by the mid-2020s. This scenario considers high growth in the North of Dryden Sub-Region, and assumes that all load on circuit E1Cwill be supplied by the proposed 230 kV line to Pickle Lake. The IRRP identified one option for meeting the need of the 115 kV system to install a third autotransformer at Dryden TS. A recommended plan has not been finalized at this time given the long lead time and uncertainty associated with potential developments in the area. The next cycle of Regional Planning will reassess the need.

6.3.2 Kenora Needs and Plans

The transformer station supplying the City of Kenora and surrounding areas ("Kenora MTS") can supply 25 MW. This transformer station currently supplies up to 20 MW. Since the increase in the residential and commercial load in the Kenora area is forecast to be modest over the planning period, the remaining 5 MW margin will be adequate for the Kenora area.

The IRRP has identified that an industrial customer, currently supplied by a local generating station is considering pursuing an alternative supply arrangement from Kenora MTS. Furthermore, potential developments at the former Abitibi mill site may also require additional transformer station capacity in the Kenora area. The magnitude and timing of these developments remains uncertain and is not expected to have major regional implications. No actions were recommended in the IRRP to address the need at this time.

6.3.3 Moose Lake Needs and Plans

The Moose Lake 115 kV sub-system has sufficient supply capacity to meet demand in the planning horizon under each load growth scenario. Therefore, no actions were recommended in the IRRP at this time.

6.3.4 Fort Frances Needs and Plans

The Fort Frances 115 kV sub-system was found to have sufficient supply capacity to meet demand in the planning horizon under each load growth scenario. Therefore, no actions were recommended in the IRRP at this time.

6.4 Thunder Bay Sub-Region

The IRRP for the Thunder Bay sub-region [5] considered low, medium and high load growth scenarios and identified near/mid/long-term needs and recommendations for each scenario. The assessments of this sub-region have assumed that the most impactful scenario in the Greenstone sub-system will materialize, resulting in 60 MW supply need from the Thunder Bay sub-region (i.e. on circuit A4L in case it would be upgraded).

The low load growth scenario has forecast the peak demand of close to 325 MW in 2015 will decline to about 300 MW by 2035 as a result of continuing decline in the pulp and paper sector and without new mining or industrial developments in Thunder Bay.

In the medium load growth scenario, involving new mines and industrial load (one pumping station of the Energy East gas-to-oil pipeline development supplied from the Thunder Bay transmission system) and no change in the pulp and paper sector, the load is forecasted to increase to 400 MW in 2035. This is comparable to the sub-region's historic peak demand in 2006/2007.

In the high load growth scenario, involving additional transmission connected mining developments north of Thunder Bay; the load is forecasted to increase to 415 MW by the end of planning period.

In addition to the potential long-term wires options for medium/high growth scenarios described below, the IRRP for Thunder Bay sub-region identified the near-term need for upgrading the thermal rating of circuit R2LB between Lakehead TS and Birch TS to that of the companion circuit R1LB. This work has been completed.

6.4.1 Long-Term Needs and Plans

Port Arthur TS - Transformation Capacity

The long-term load forecast indicates that the demand from the customers supplied by Port Arthur TS will exceed the station's current capacity by 2033, and additional station capacity will be required if this load growth materializes.

Currently, the low voltage equipment at Port Arthur TS are limiting the station capacity to 55 MW. The station transformers provide up to 59 MW of capacity.

<u>Wires Option:</u>

The low voltage equipment, which are limiting the station capacity are nearing end-of-life and are planned to be replaced and upgraded in mid-term. This upgrade would bring the station capacity up to 59 MW, sufficient to meet the need beyond 2035. No additional plan is required at this time and load at Port Arthur TS will be monitored and supply options will be assessed in the next cycle of Regional Planning.

Lakehead TS and Birch TS - Transformation Capacity

Currently the Thunder Bay 115 kV system can accommodate approximately 150 MW of additional load growth. This capacity is sufficient under the low and medium load growth scenarios in the long-term.

Under the High growth scenario, and assuming the most impactful Greenstone sub-system scenario (60 MW, as described above), the Thunder Bay system would require additional supply capacity of approximately 20 MW by 2030.

The Thunder Bay IRRP indicates that a firm plan to increase the LMC of the Thunder Bay 115 kV system is not required at this time, as the large margin remaining on the system provides significant lead time for the Working Group to monitor demand growth and study options. The IRRP report explored various wires and non-wires options as potential long term solutions to increase the LMC of the system, however no action beyond monitoring is recommended at this time.

The wires options discussed in the Thunder Bay IRRP are described below:

1. Installing a third 230/115 kV 250 MVA autotransformer at Lakehead TS to increase the LMC of Lakehead TS by approximately 240 MW.

2. A new 230 kV line from Lakehead TS to Birch TS and a 230 kV 250 MVA autotransformer at Birch TS to create a supply point for the southern part of Thunder Bay, with a supply capacity of 240 MW. The new 230 kV line would require a new Right-of-Way and would take 5 years or longer to build.

.

7. CONCLUSIONS AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE NORTHWEST ONTARIO REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This section provides a summary of the Needs and Plans for the Northwest Region as identified in this RIP.

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. However, the Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the regional planning cycle will be started earlier to address the need.

North of Dryden Sub-Region Wires Plans

No.	Need	Wires Options	Load Growth	Term	Status
1	Circuits E1C and E4D Capacity	A 230 kV transmission line from Dryden/Ignace area to Pickle Lake	Medium[1]	Near-term	Recommended in IRRP. Development has started.
2	Circuits E4D and E2R Capacity	Upgrade of transmission lines E2R and E4D, and additional voltage support	All Scenarios	Near-term	Recommended in IRRP. The need has not materialized.
3		A 115 kV or 230 kV transmission line from Dryden to Ear Falls	High	Long-term	Proposed in IRRP. Not needed in the planning horizon, assuming Projects 1 and 2 proceed.

Greenstone-Marathon Sub-Region Wires Plans

No.	Need	Wires Options	Load Growth	Term	Status
4	Circuit A4L Capacity	Upgrade of sections of transmission line A4L, and dynamic voltage support devices at Geraldton	Medium[2]	Near-term	Recommended in IRRP. Subject to the plans and timelines for connection of a new Geraldton mine.
5		Upgrade of other sections of transmission line A4L	Medium[2]	Mid-term	Recommended in IRRP. Subject to the plans and timelines for connection of a new Beardmore mine.
6	Capacity for Pipeline Project and Ring of Fire	A 230 kV transmission line from Nipigon or Terrace Bay to Geraldton, and voltage support devices	High[2]	Mid/Long-term	Recommended in IRRP. Subject to the plans and timelines for connection of pipeline loads and mines.
7		A 115 kV transmission line from Manitouwadge to Geraldton, and voltage support devices	High[2]	Long-term	Recommended in IRRP. Subject to the plans and timelines for connection of additional pipeline loads.

West of Thunder Bay Sub-Region Wires Plans					
No.	**Need**	**Wires Options**	**Load Growth**	**Term**	**Status**
8	Dryden 115 kV System Capacity	A 230/115 kV auto-transformer in Dryden area	High	Mid-term	Proposed in IRRP. Next planning cycle will reassess the need.

Thunder Bay Sub-Region Wires Plans					
No.	**Need**	**Wires Options**	**Load Growth**	**Term**	**Status**
9	Thunder Bay 115 kV System Capacity	A 230/115 kV auto-transformer in Thunder Bay area	High	Long-term	Proposed in IRRP. Next planning cycle will reassess the need.
10	Port Arthur TS Transformation Capacity	Upgrade of Low-Voltage equipment at Port Arthur TS	All Scenarios	Long-term	Proposed in IRRP. LV equipment are planned for End-of-Life replacement in mid-term. Next planning cycle will reassess the need.

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional near and mid-term needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE WINDSOR-ESSEX REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator
- E.L.K. Energy Inc.
- Entegrus Powerlines Inc.
- EnWin Utilities Ltd.
- Essex Powerlines Corporation
- Hydro One Networks Inc. (Distribution)

This RIP provides a consolidated summary of needs and recommended plans for Windsor-Essex Region. No long-term needs (10 to 20 years) and associated plans have been identified.

This RIP is the final phase of the regional planning process and it follows the completion of the Windsor-Essex Region Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015 [1].

The major infrastructure investments planned, or being planned, for the Windsor-Essex Region over the near and medium-term identified in the various phases of the regional planning process are given in the table below.

No.	Project	I/S Date	Cost
1*	Supply to Essex County Transmission Reinforcement (SECTR TX) Project	June 2018	$77.4M
2*	Supply to Essex County Transmission Reinforcement (SECTR DX) Project	June 2018	$19.3M
3	Replacement of Keith end-of-life autotransformers	2020	$45M
4	Replacement of Kingsville end-of-life transformers	2018	$12M
5	230kV/115kV circuit and 27.6kV feeder reconfiguration at Keith TS due to Gordie Howe International Bridge (GHIB) Project	2018	$63M
6	Additional feeder position at Malden TS	TBD	TBD
7	Decommission of Tilbury TS	2019	TBD
8	Decommission of T1 Transformer at Keith TS	TBD	TBD

* These projects address the needs identified in the Windsor-Essex IRRP study for the region in the near and medium-term.

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. Should there be any new needs that emerge due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

TABLE OF CONTENTS

LIST OF TABLES

[This page is intentionally left blank]

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE WINDSOR-ESSEX REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") and documents the results of the joint study carried out by Hydro One, EnWin Utilities Ltd. ("EnWin"), Essex Powerlines Corporation, E.L.K. Energy Inc. ("E.L.K Energy"), Entegrus Inc. ("Entegrus"), Hydro One Networks Inc. (Distribution) ("Hydro One Distribution), and the Independent Electricity System Operator ("IESO") in accordance with the regional planning process established by the Ontario Energy Board ("OEB") in 2013.

The Windsor-Essex Region comprises the City of Windsor, Town of Amherstburg, Town of Essex, Town of Kingsville, Town of Lakeshore, Town of LaSalle, Municipality of Leamington, Town of Tecumseh, the western portion of the Municipality of Chatham-Kent and the Township of Pelee Island. The map of the region is shown in Figure 1-1 below.

The Windsor-Essex area is supplied from a combination of generation located in the region and from the Ontario grid via a network of 230 kV and 115 kV transmission lines and stations. The region peak electricity demand of about 800 MW is provided from three 230 kV and fourteen 115 kV step-down transformer stations.

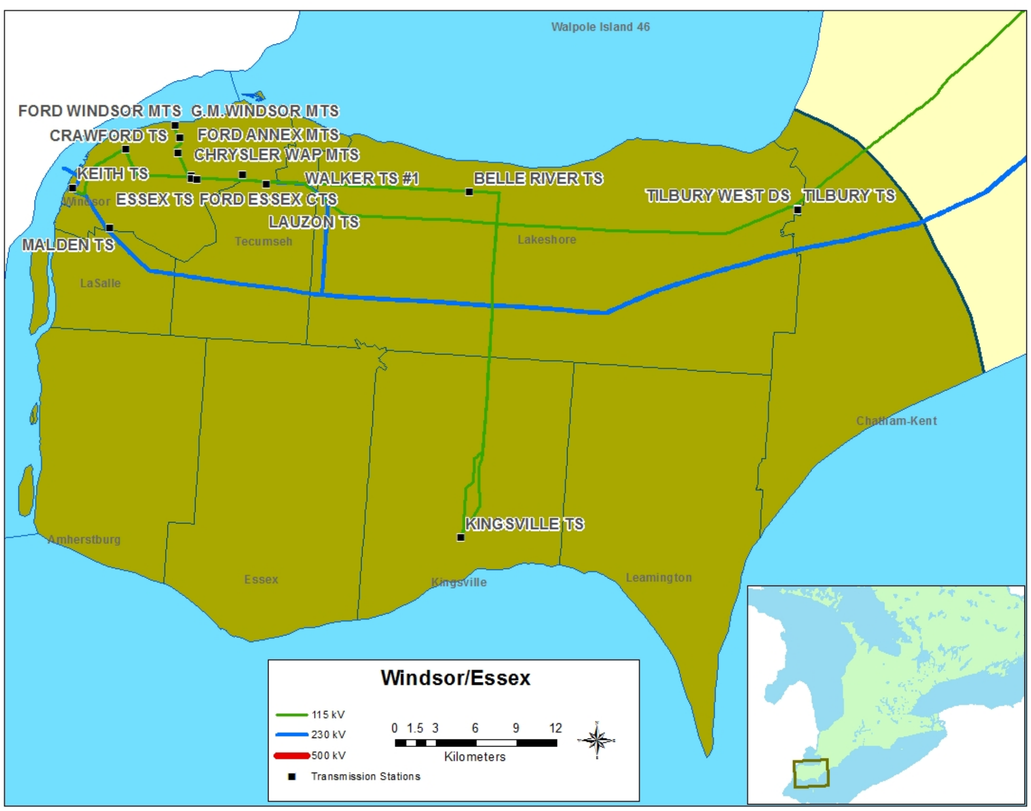

Figure 1-1 Geographical Map of Windsor-Essex Region

1.1 Scope and Objectives

This RIP report examines the needs in the Windsor-Essex Region. Its objectives are to: identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment ("NA"), Scoping Assessment ("SA"), Local Plan ("LP"), and/or Integrated Regional Resource Plan ("IRRP")); assess and develop wires plans to address these needs; provide the status of wires planning currently underway or completed for specific needs; and identify investments in transmission and distribution facilities or both that should be developed and implemented to meet the electricity infrastructure needs within the region.

Planning activities for the Windsor-Essex Region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete and the Windsor-Essex Region was identified as a "transitional" region. The planning status for the region was considered to be in the IRRP phase of the regional planning process. An IRRP for the region was completed in April 2015.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2015-2025) identified in previous planning phases (NA, SA, LP, and/or IRRP).
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated information.
- Develop a plan to address any longer term needs identified by the Working Group.

The IRRP or RIP Working Group did not identify any long term needs at this time. If required, further assessment will be undertaken in the next planning cycle because adequate time is available to plan for required facilities.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the region.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the regional needs.
- Section 7 provides a summary of regional plans.
- Section 8 provides summary of other projects.
- Section 9 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a

[1] Also referred to as Needs Screening

need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region. Since the Windsor-Essex Region was in transition to the new regional planning process, the IESO led IRRP engagement for this region was initiated after the completion of the IRRP.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

The regional planning process specifies a 20 year planning assessment period for the IRRP. The RIP focuses on the wires options and, given the forecast uncertainty and the fact that adequate time is available to identify and plan new wire facilities in subsequent planning cycles, a study period of 10 years is considered adequate for the RIP. The exception would be the case where major transmission infrastructure investments are required. In these cases the RIP would review and assess longer term needs and develop a longer term plan.

To efficiently manage the regional planning process in the region, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- Participating in and conducting wires planning as part of the IRRP for the region.
- Working and planning connection capacity requirements with the LDCs.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

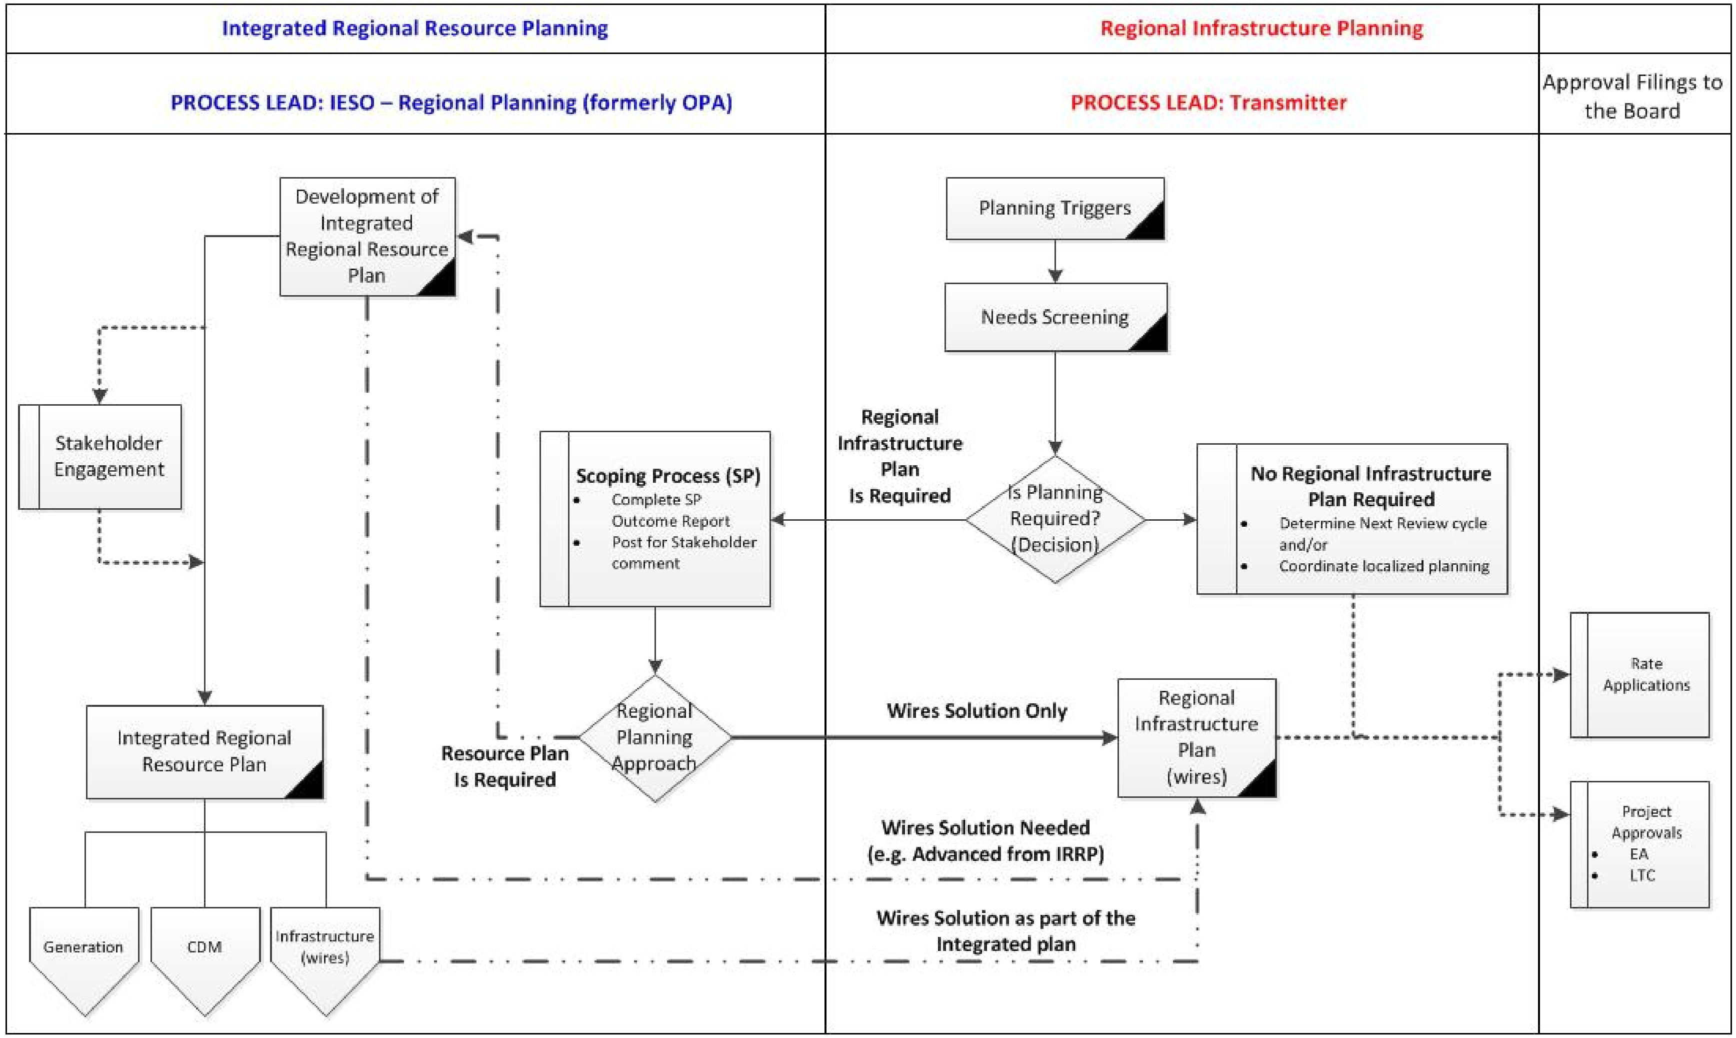

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP process is a four step process as shown in Figure 2-2 below.

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

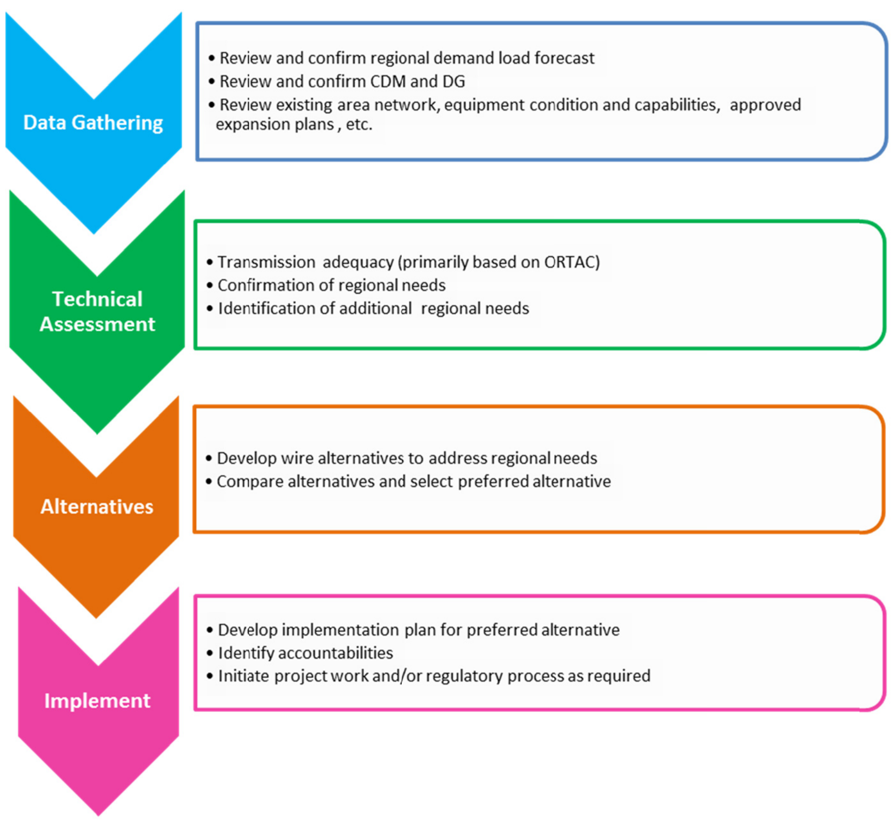

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE WINDSOR-ESSEX REGION COMPRISES THE CITY OF WINDSOR, TOWN OF AMHERSTBURG, TOWN OF ESSEX, TOWN OF KINGSVILLE, TOWN OF LAKESHORE, TOWN OF LASALLE, MUNICIPALITY OF LEAMINGTON, TOWN OF TECUMSEH, THE WESTERN PORTION OF THE MUNICIPALITY OF CHATHAM-KENT AND THE TOWNSHIP OF PELEE ISLAND.

The region is served by five LDCs: EnWin, Essex Powerlines Corporation, E.L.K. Energy, Entegrus, and Hydro One Distribution, whose service territories are shown in Figure 3-1. EnWin and Hydro One Distribution are directly connected to the transmission system, while the three other LDCs have low voltage connections.

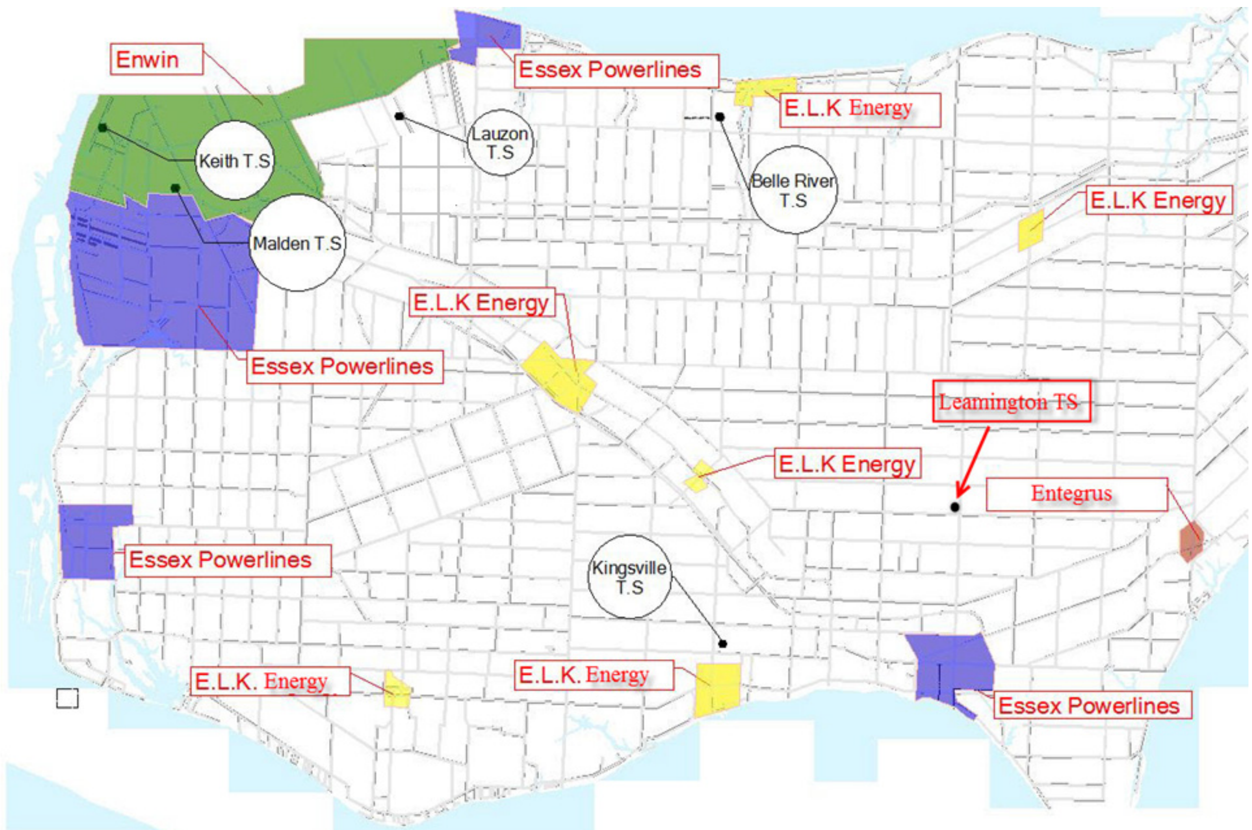

Figure 3-1 LDC Service Territories

The region peak electricity demand of about 800 MW is supplied from a combination of local generation and from connection to the Ontario grid via a network of 230 kV and 115 kV transmission lines and stations shown in Figure 3-2 below.

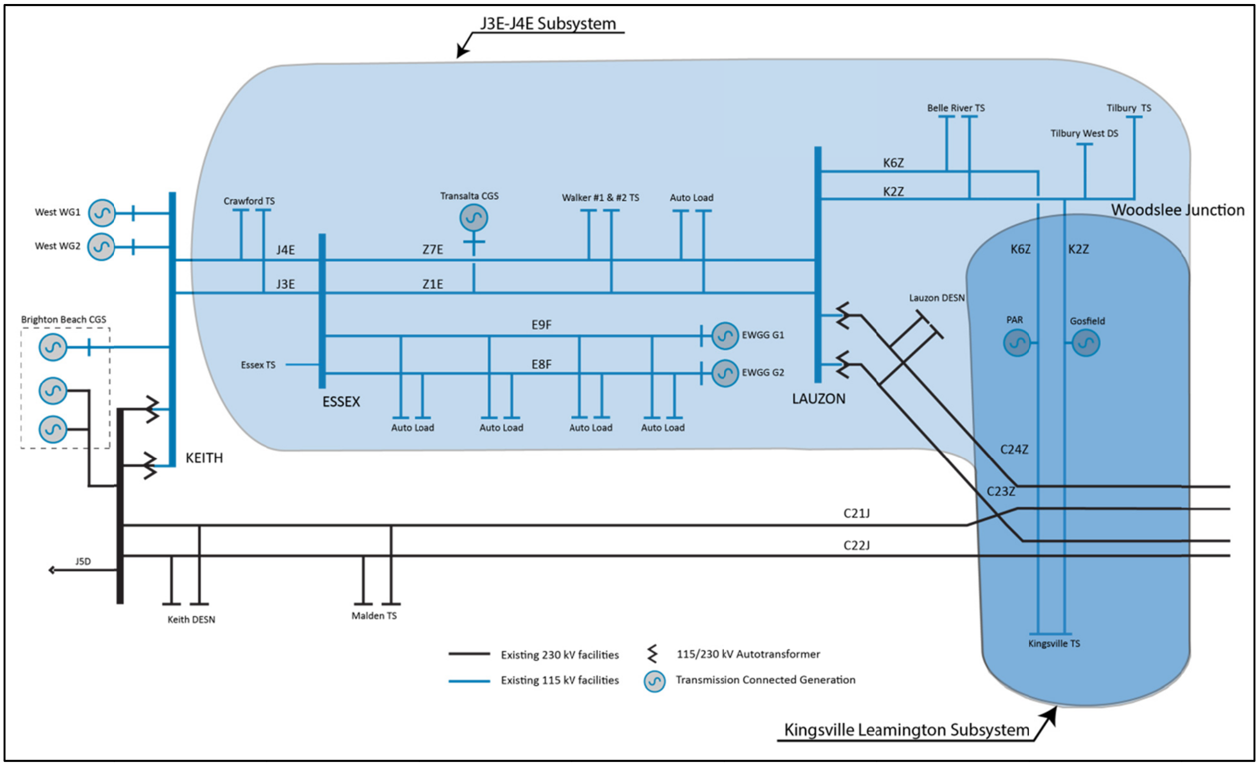

Figure 3-2 Windsor-Essex Area Subsystems/Single Line Diagram

The main transmission corridor in the region connects with the rest of the Hydro One system at Chatham Switching Station ("SS") and connects the Ontario transmission system with the Michigan transmission system at Keith TS.

The region's 115 kV network connects to the 230 kV transmission system at Keith TS and Lauzon TS via two auto-transformers in each station. About 65% of the area load is supplied by fourteen step-down transformers stations connected to the 115 kV network, while the balance is supplied by three step-down transformer stations connected to the 230 kV network. Table 3-1 lists the region's step-down transformer stations.

There are six customer-owned generating plants in the region connecting at the 230 kV and 115 kV levels with a combined contract capacity of 927 MW. In addition, the distributed generation connected at various locations to low-voltage ("LV") feeders in the region account for about 65 MW of effective capacity. Table 3-1 list the region's transmission connected generations.

The transmission system in the region can be divided into two "nested" sub-systems:

- The Kingsville-Leamington subsystem: customers supplied from Kingsville TS and
- The J3E-J4E subsystem: customers supplied from stations connected to the Windsor-Essex 115 kV system, as well as customers supplied from the 230/27.6 kV Lauzon DESN.

As can be noted in Figure 3-2 below, the Kingsville-Leamington subsystem is nested within the J3E-J4E subsystem. Therefore, increasing supply to the Kingsville-Leamington subsystem or transferring load from the existing Kingsville TS to a new 230 kV TS will impact the supply and demand balance in the J3E-J4E subsystem.

Table 3-1 Stations Included in the Windsor-Essex Region

Station (DESN)	Voltage Level (kV)	Supply Circuits	Connected Customer(s)

4. TRANSMISSION FACILITIES COMPLETED OVER THE LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED OR ARE UNDERWAY BY HYDRO ONE, AIMED AT IMPROVING THE SUPPLY TO THE WINDSOR-ESSEX REGION. A BRIEF LISTING OF THE COMPLETED PROJECTS OVER THE LAST 10 YEARS IS GIVEN BELOW:

- Belle River TS (May 2006): Built a new 2-25/33/42 MVA 115/27.6 kV transformer station in the Town of Lakeshore supplied from 115 kV circuits K2Z/K6Z. The station provides additional load supply capability to meet the load requirements of Hydro One Distribution customers in the Town of Lakeshore. The connection of new station required the untwining of K6Z to obtain two circuits (K2Z and K6Z) with K6Z on the north side of the towers. The new K2Z circuit section which only extends to Belle River TS was then connected to the then existing K2Z circuit just outside of Lauzon TS.

- Essex TS (October 2008): The station was refurbished with new 2-50/66/83 MVA 115/27.6 kV transformers. The 115 kV supply circuits were reconfigured to mitigate exposure to customer load loss for loss of a single transmission element under certain system conditions.

- Malden TS: Transformer T2 75/100/125 230/27.6 kV was replaced (July 2010) and T1 was replaced (December 2011).

- Keith TS: T23 transformer 50/67/83 MVA 230/27.6 kV was replaced (October 2008) and T22 transformer 50/67/83 MVA 230/27.6 kV was replaced (December 2013).

- Walker TS #1: Reactor installation for short circuit mitigation (June 2011).

- Kingsville TS: Reactor installation for short circuit mitigation (November 2011).

- Keith TS: Reactor installation for short circuit mitigation (April 2012).

- Lauzon TS: Three breakers were replaced: SC2Q (June 2012), SC3E (April 2012) and SC4J (April 2012).

- Keith TS: Six breakers were replaced: SC11K (May 2014), SC11SC (May 2014), SC1B (June 2014), T11P (August 2014), T12P (October 2014), SC2Y (January 2015).

The following projects are currently underway:

- Crawford TS: is a 115/28 kV, with two 50/67/83 MVA units in Windsor. It supplies the downtown Windsor area with a current peak load of 60 MW. The existing T3 transformer is at the end-of-life with leaky fittings and headboard. The T3 fire suppression system and separation wall also needs to be upgraded to current standards. The current plan is to replace T3 transformer and install neutral grounding reactors on the T3 and T4 transformer units. The project includes protection and control upgrades and relocation of battery, necessary spill containment facilities at Crawford TS. The project is under execution for $8.46 million with an in-service date of December 15, 2016. There are no cost implications for the LDCs. Once this project is complete the station will meet the current design standards.

5. LOAD FORECAST AND OTHER ASSUMPTIONS

THE FORECASTS REFLECT THE EXPECTED PEAK DEMAND AT EACH STATION UNDER EXTREME WEATHER CONDITIONS, BASED ON FACTORS SUCH AS POPULATION, HOUSEHOLD AND ECONOMIC GROWTH, CONSISTENT WITH MUNICIPAL PLANNING ASSUMPTIONS.

5.1 Historical Demand

The peak demand in the Windsor-Essex Region has declined from a high of 1060 MW in the summer of 2006 to approximately 800 MW in both 2013 and 2014.

Figure 5-1 shows the historical summer peak demand observed in the region from 2004 to 2014. A noticeable peak in 2006 is coincident with the all-time peak in Ontario power demand, while a dip in 2008 and 2009 shows the area's response to the global recession. There is a large concentration of automotive manufacturing facilities in the City of Windsor. The sector is a major economic driver and electricity user within the region. The decline in Ontario's manufacturing sector and the 2008/09 economic downturn have both contributed to a decline in electricity use in the region.

While the manufacturing sector continues to face challenges in recovering, economic diversification is changing the region's growth and electricity use. The five-year Windsor-Essex Regional Economic Roadmap, released in 2011, identifies nine industry groups that hold growth potential for the region, including advanced manufacturing, tourism, and agri-business.

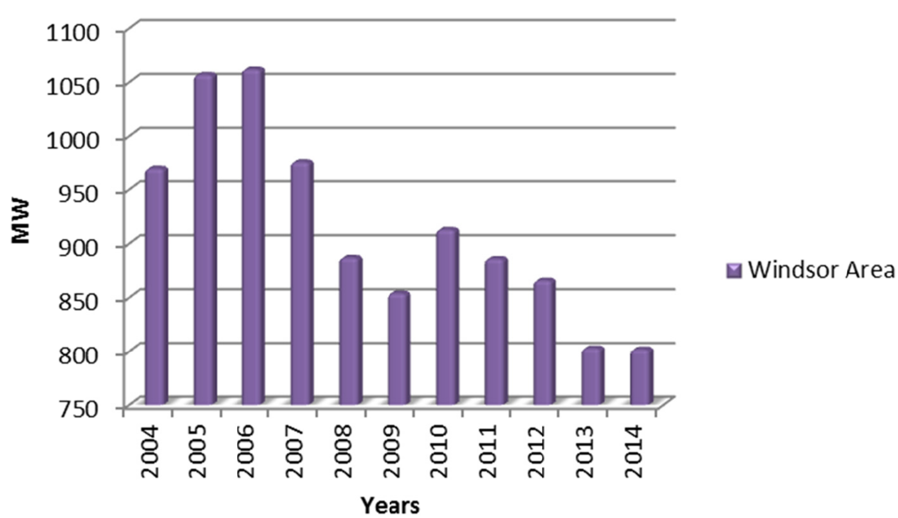

Figure 5-1 Historical Load Demand in Windsor-Essex Region

The peak demand in the Kingsville-Leamington area has also experienced fluctuations over the 2004-2014 period as shown in Figure 6-1.

5.2 Contribution of CDM and DG

In developing the planning forecast, the following process was used to assess the Windsor-Essex Region:

a) First, "gross demand" is established. Gross demand reflects the forecast developed and provided by the area LDCs and is influenced by a number of factors such as economic, household and population growth.
b) Second, "net demand" is derived by reducing the gross demand by expected savings from improved building codes and equipment standards, customer response to time-of-use pricing, and projected province-wide CDM programs. This information is provided by the IESO.
c) Lastly, a "planning forecast" is determined by reducing net demand by the contribution in the area from existing, committed and forecast DG. This information is provided by the IESO.

5.3 Gross and Net Demand Forecast

Summer peak gross non-coincident demand forecasts for the 20-year planning horizon were provided by EnWin and Hydro One Distribution, the two LDCs which are directly connected to the transmission system, for each of the transformer stations in the area. The forecasts from Hydro One Distribution include forecasts provided by the appropriate embedded LDCs.

The development of the load forecast for this RIP report followed a two-stage process:

(a) Using the forecast provided by the LDCs, the year by year growth rate for each station was first developed.
(b) The 2014 summer actual peak load, corrected for extreme weather, for each station was obtained.
(c) The growth rates from (a) were then applied to the 2014 summer peak load of (b) to obtain the gross load forecast for each station for extreme weather conditions.

The gross load forecasts, for extreme weather conditions, by station and by subsystem are shown in Appendix A. This load forecast reflects the following:

- A shift of load, commencing in 2016, from Walker TS #1 and #2 to Essex TS and GM MTS.
- Reduction in Kingsville TS load.
- Increase in loads at Keith TS, Crawford TS and Lauzon TS.

The gross load forecasts, for extreme weather conditions, by station and by subsystem are shown in Appendix A. Figure 5-2 is a graph of the Windsor – Essex Region extreme weather peak summer non-coincident load forecast. The overall region will experience an average annual growth rate of just less than 1%, while the Kingsville-Leamington area average growth rate would be about 1.6%.

Figure 5-2 also shows the load forecast from the IRRP report. The two forecasts are not materially different; hence the load forecast in this RIP report will not alter the conclusions of the IRRP.

The Reference Planning forecast (Appendix D) for each station is obtained by reducing the gross load forecast for the station by the amount of forecast conservation and DG. The conservation forecast (Appendix B) and the DG forecast (Appendix C) are the same as used in the IRRP report.

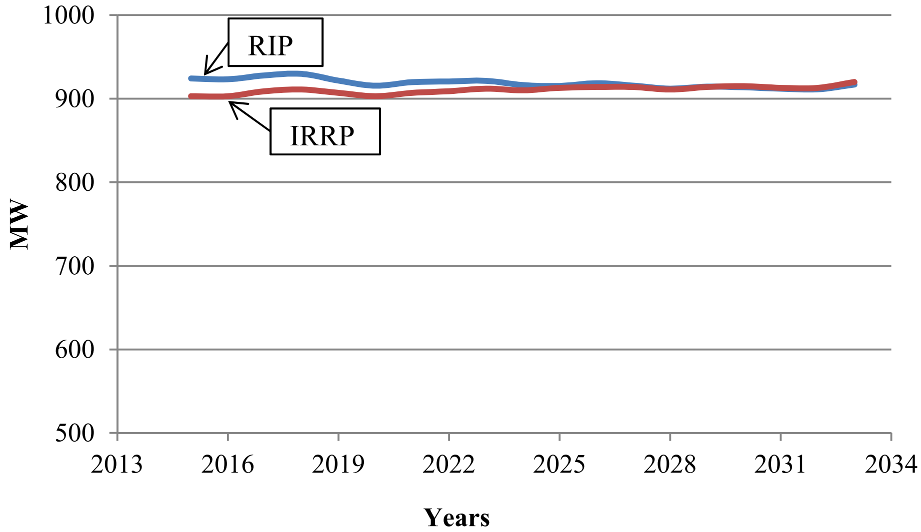

Figure 5-2 Reference Forecast in Windsor-Essex Region

5.4 Other Study Assumptions

The following other assumptions are made in this report.

1) The Study period for the RIP assessment is 2015-2025.
2) All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
3) Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
4) Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity. Load is assumed at 90% lagging power factor, unless known.
5) Normal planning supply capacity for Hydro One transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR), while some LDCs use different methodologies for determining transformer station LTR.

6. REGIONAL NEEDS

THIS SECTION SUMMARIZES THE WINDSOR-ESSEX REGION NEEDS OVER THE NEAR AND MID TERM. NO LONG TERM NEEDS HAVE BEEN IDENTIFIED.

Earlier studies by the IESO, ("Windsor-Essex Region Integrated Regional Resource Plan" - April 28, 2015, Supply to Essex County Transmission Reinforcement Project, January 2014) identified two near-term needs in the region. These needs are:

- **Minimize the Impact of Supply Interruptions in the J3E-J4E Subsystem:**
  The existing system lacks the capability to restore power to customers in the J3E-J4E subsystem in accordance with the ORTAC criteria, i.e., restoration of all loads within 8 hours. Based on current and forecast demand, up to 170 MW 0f the load interrupted cannot be restored by 2017.

- **Additional Supply Capacity in the Kingsville-Leamington Area:**
  Demand in the Kingsville-Leamington subsystem has already exceeded the load meeting capability of 120 MW in recent 3 years and is expected to continue to exceed the supply capacity over the forecast period. Figure 6-1 below shows the historical and forecast demand and supply capabilities in the Kingsville-Leamington subsystem after conservation and DG are taken into consideration.

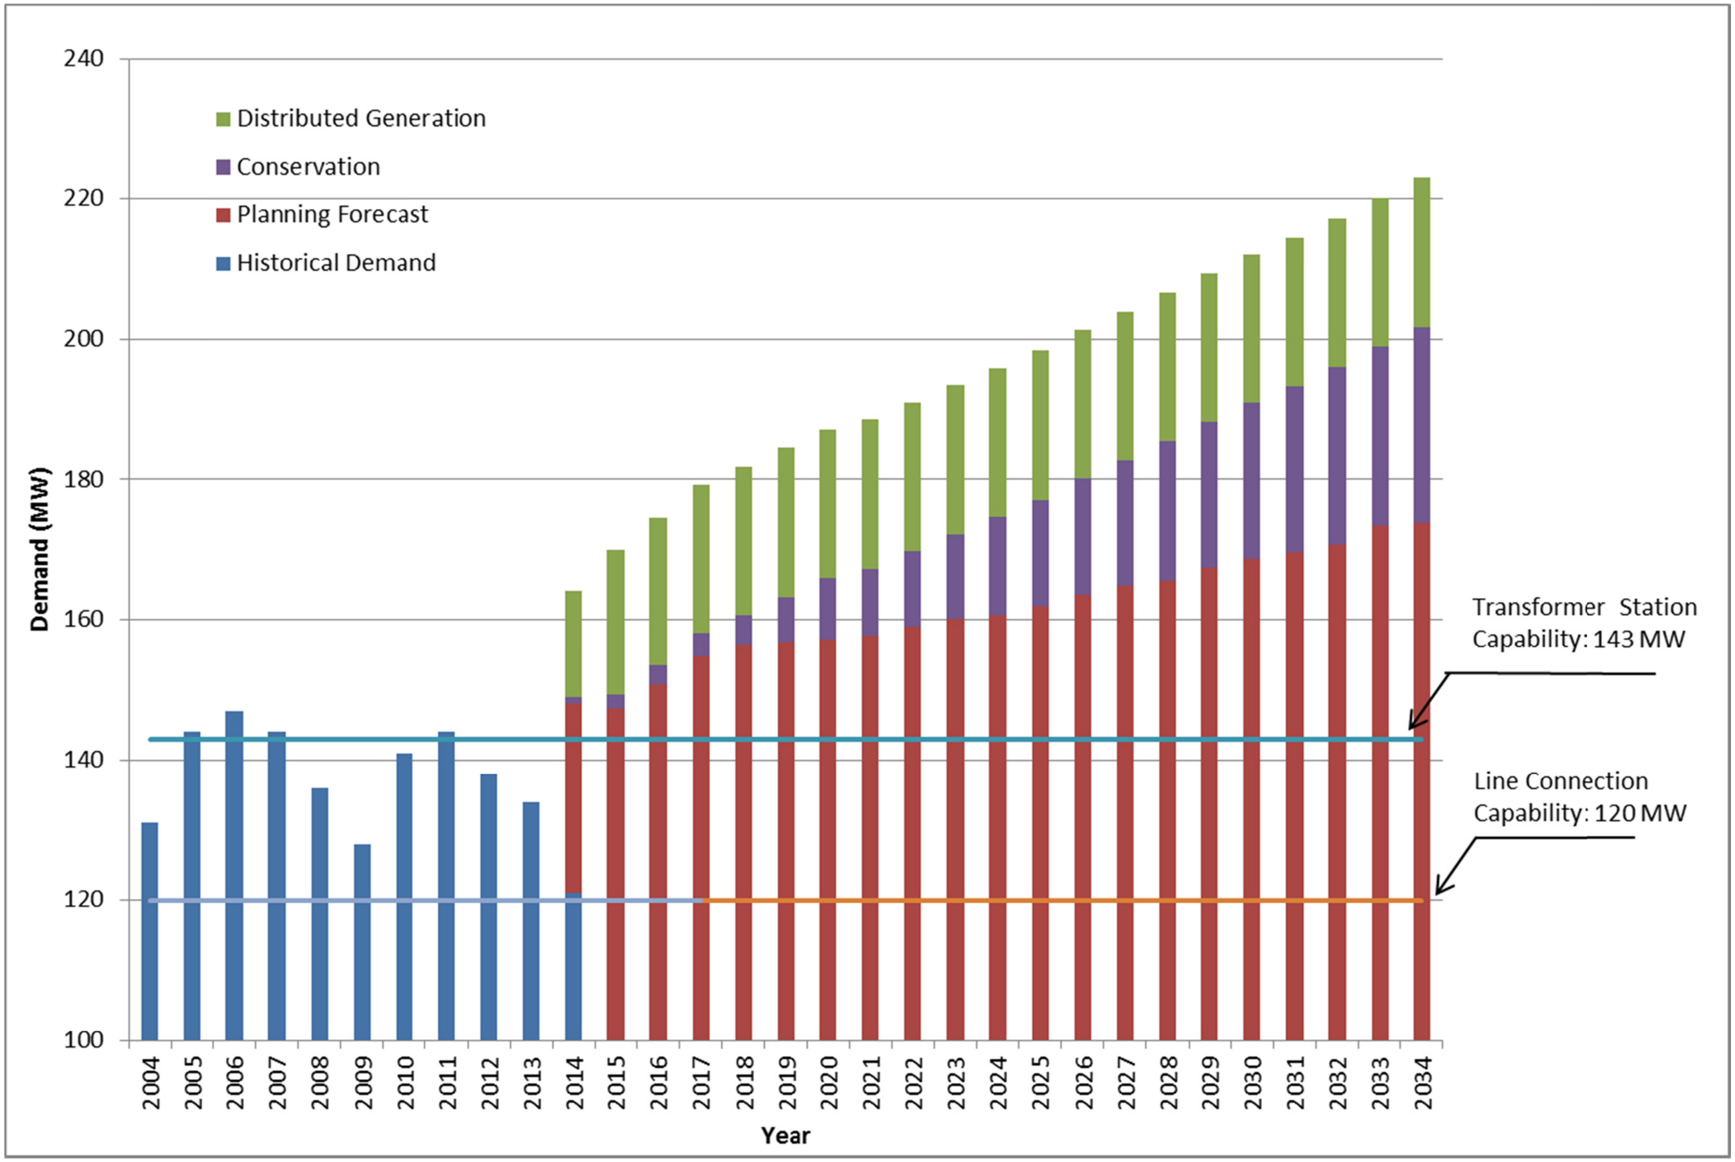

Figure 6-1 Historical and Forecast Demand of Kingsville-Leamington Subsystem

In addition, Hydro One has also identified infrastructure and major equipment which need replacement during the study period. The current plan is essentially a like-for-like replacement of 3 step-down transformers at Kingsville TS and 2 auto-transformers at Keith TS.

These regional needs are summarized in Table 6-1 and include needs for which work is already underway and/or being addressed. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

Table 6-1 Summary of Needs

Type	Needs	Timeline	Process
Capacity to Meet Demand	Kingsville-Leamington Subsystem	2018	**IRRP**
Minimize the Impact of Interruption	J3E-J4E Subsystem	2018	**IRRP**
Aging Equipment Replacement	3 transformers at Kingsville TS are at end-of-life	Near-Term	**RIP**
Aging Equipment Replacement	2 autotransformers at Keith TS are at end-of-life	Near-Term	**RIP**

7. REGIONAL INFRASTRUCTURE PLANS

THIS SECTION PRESENTS WIRES ALTERNATIVES AND THE CURRENT PREFERRED WIRES SOLUTION FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE WINDSOR-ESSEX REGION.

7.1 Supply to Essex County Transmission Reinforcement (SECTR) Project

7.1.1 Description

The SECTR project as presented in the IRRP is an integrated solution to address both the J3E-J4E subsystem restoration need and the Kingsville – Leamington capacity need. As illustrated in Figure 7-1 the project consists of the installation of a new 230 kV supplied transformer station near Leamington connected to the existing C21J/C22J circuits via a new 13 km double-circuit 230 kV connection line on a new right-of-way.

The total cost of this project is $96.7M made up of:

(a) Build 230/27.6 – 27.6 kV 75/100/125 MVA Leamington TS with six LV breaker positions, plus other required switchgear: $32.1M
(b) Build a 13 km 2-circuit 230 kV line on a new right-of-way tapping into existing 230 kV circuits C21J/C22J plus Optical Ground Wire: $45.3M.
(c) Carry out distribution work for Leamington TS: $19.3M. Other additional distribution work includes two additional feeder positions at Leamington TS, and protection upgrades for in-service Kingsville DG transferred to Leamington TS.

With the establishment of Leamington TS, load will be transferred from Kingsville TS to the new station, such that the Kingsville TS load will be reduced to about 50 MW. As discussed in the IRRP report, this presents an opportunity to downsize the station from four transformers to two transformers, and would result in a combined supply capability in the Kingsville-Leamington area of 210 MW.

Figure 7-2 is a preliminary plan for the transfer of Kingsville TS feeders to Leamington TS. Feeders which are shown in blue will be completely transferred to Leamington TS, and the ones shown in green will be partially transferred to Leamington TS.

7.1.2 Recommended Plan and Current Status

Hydro One filed an application on January 22, 2014 with the OEB under Section 92 of the OEB Act for an order granting leave to construct approximately 13 km of new 230 kV transmission lines on steel lattice towers on a new right of way in the Windsor-Essex area and the installation of optic ground wire for system telecommunication purposes on existing C21J/C23Z towers near Leamington Junction and on new 230 kV towers. The application included a request for OEB approval of the methodology for allocating project cost to Hydro One Distribution, embedded LDCs and Sub-Transmission class customers.

On February 12, 2015, Hydro One filed an updated application that included the new 230/27.6 kV Leamington Transformer Station (Leamington TS). The OEB decided that the proceeding would be addressed in two phases. Phase 1 would only deal with the leave to construct application and Phase 2 of the proceeding would deal with cost allocation. Phase 1 of the SECTR S.92 proceeding has concluded and the "Leave to Construct" approval was granted by the OEB on July 16, 2015. The expected in-service date for the SECTR Project is June 2018. Phase 2 of the proceeding is continuing via an OEB policy review rather than the originally planned adjudicative process.

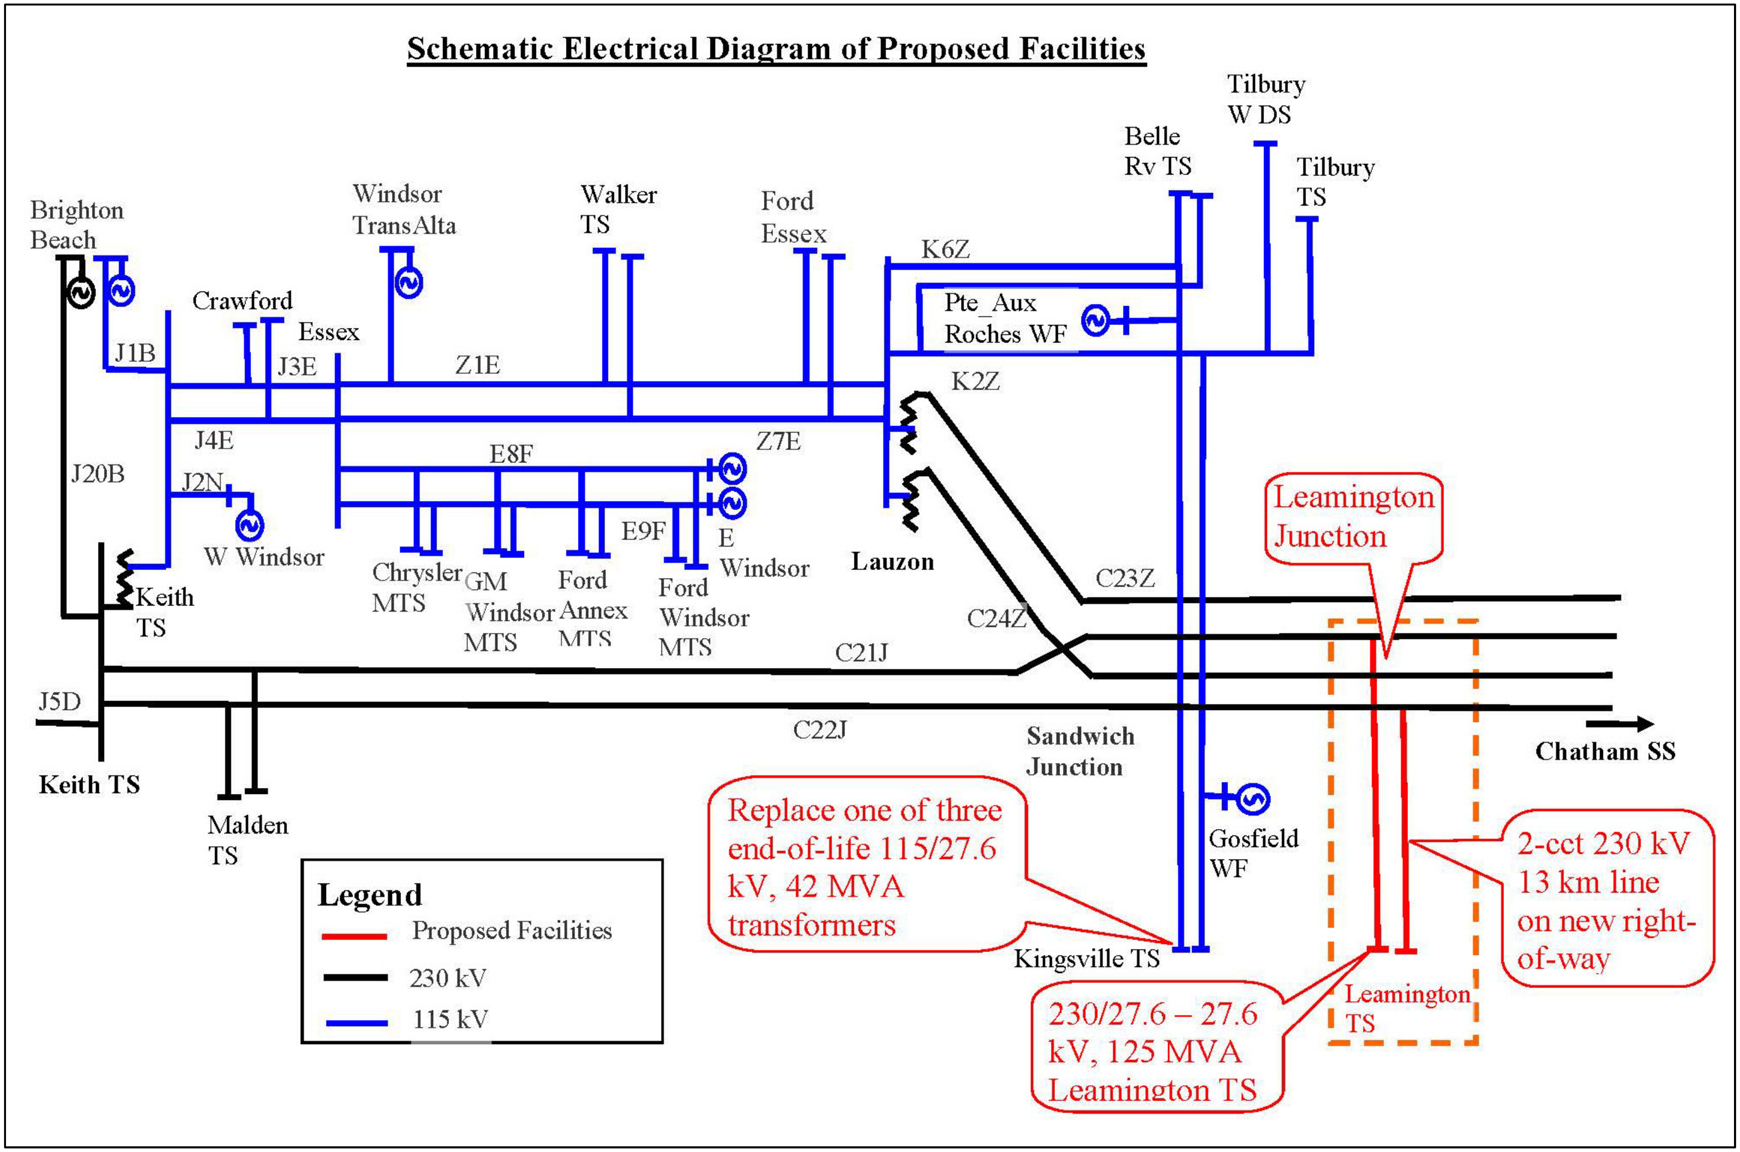

Figure 7-1 Schematic Electrical Diagram of the Proposed Facilities

Figure 7-2 Preliminary Distribution Feeder Plans for SECTR Project

7.2 Keith TS End-of-Life Auto-Transformer Replacement

7.2.1 Description

Keith TS is equipped with 2-230/115 kV 115 MVA autotransformers. These autotransformers are 1950's vintage and near end-of-life and require replacement.

7.2.2 Recommended Plan and Current Status

Due to SECTR project additional capacity will not be required and the end-of-life autotransformers at Keith TS will be replaced with equivalent like-for-like 125 MVA units. The expected in-service date is 2020. There are no cost implications for the LDCs.

7.3 Kingsville TS End-of-Life Transformer Replacement

7.3.1 Description

Kingsville TS is equipped with 4-115/27.6 kV 25/33/42 MVA transformers. One of these transformers was recently replaced, but the other three are 1950's vintage and will require replacement in the near future.

Due to SECTR project and the associated reduction in load at Kingsville TS, the station may be downsized and reconfigured as a two-transformer station. Hydro One Distribution is further reassessing to justify retaining the four-transformer arrangement if they receive additional request for connections at Kingsville area.

7.3.2 Recommended Plan

Hydro One Distribution to complete their connection capacity assessment as part of distribution system planning before Q3 2016 so that replacement and reconfiguration plan can be finalized by Hydro One in a timely manner.

7.4 Gordie Howe International Bridge (GHIB)

7.4.1 Description

The Gordie Howe International Bridge (GHIB) is a construction project under a bi-lateral agreement between the federal governments of Canada and the USA, and the governments of Ontario and Michigan, to construct a new border crossing between Windsor and Detroit. It will comprise a 12 km westerly extension of Hwy 401 to a site near Keith Transformer Station, where a new customs plaza and a new bridge over the Detroit River will be constructed. The highway will be extended by the Ministry of Transportation of Ontario (MTO), while the customs plaza and the bridge will be constructed by Transport Canada.

The GHIB project is multi-faceted in its impacts on Hydro One facilities and operations at Keith TS including: transmission lines, fiber lines and feeders relocation; insulation contamination due to salt spray effects from new bridge; relocation of access routes; possible security issues for staff accessing and working at the station; impacts on existing utilities (water/sewer/gas). In addition, the GHIB project will reduce the footprint of the station and encumber egress from the station. Consequently, this project will impact future expansion work at the station and possibly limit the extent to which the station can be developed relative to its ultimate plan development over the long term.

7.4.2 Recommended Plan and Current Status

In order to mitigate these impacts, as illustrated in Figure 7-3 below, additional real estate is required for future expansion to the north of McKee Rd. The existing transmission lines and feeders will also need to egress the station via underground cables so as not to interfere with the bridge operations.

The cost of this project will be fully recovered from the Windsor Detroit Bridge Authority (WDBA). A Transmission Assets Modification Agreement (TAMA) with the WDBA is expected to be finalized by early January 2016. Approvals for executing the project are expected by March 2016 for a planned in-service date by the end of 2018.

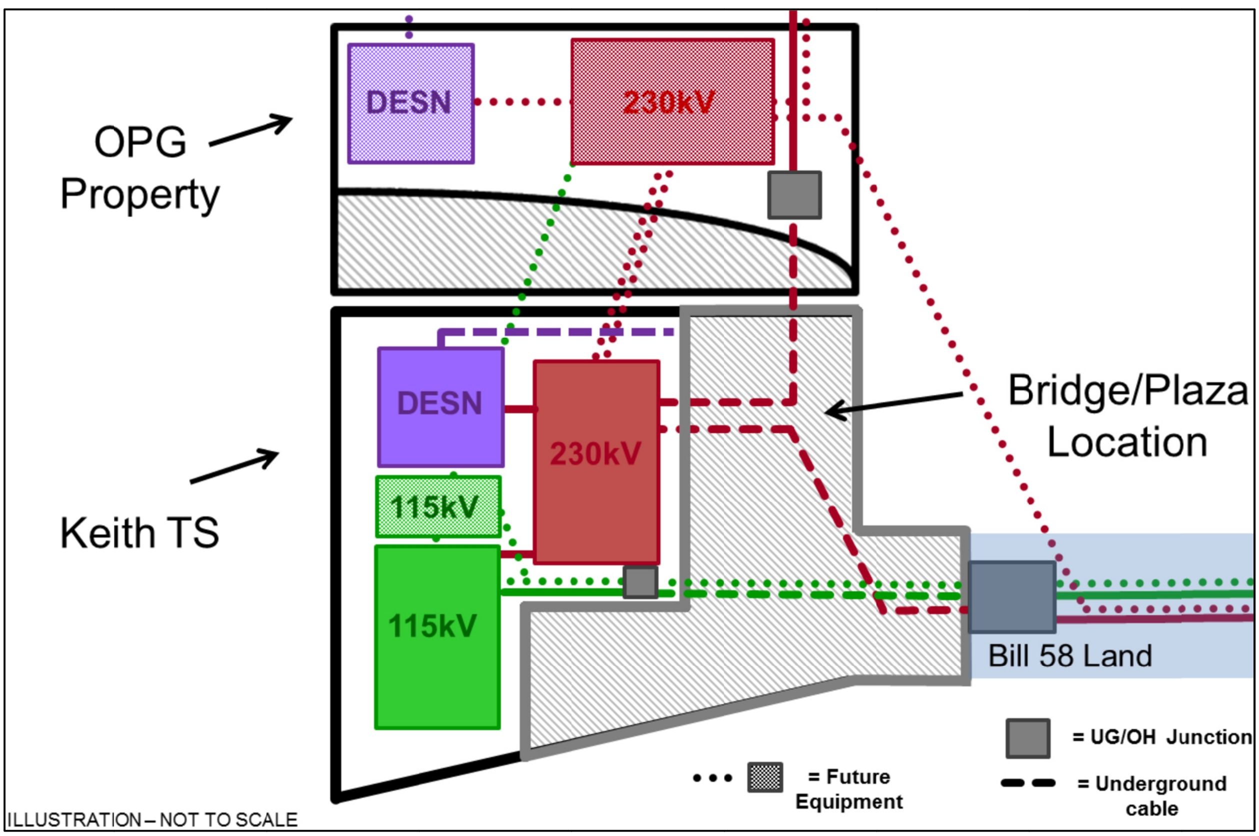

Figure 7-3 Gordie Howe International Bridge (GHIB) Project

8. OTHER PROJECTS

There are other wires projects that are currently under development and pending decision in the Windsor-Essex Region. These projects are local in nature and being planned and developed by Hydro One and relevant LDC as discussed below.

8.1 Malden TS Additional Feeder Positions

8.1.1 Description

Due to the load increase that's expected from the planned Detroit River International Crossing work and local highway construction, Essex Power has identified a need for two additional 28 kV feeder positions to be constructed at Malden TS.

The Malden transformer station is currently equipped with two 75/125 MVA transformers, 12 feeder positions and two capacitor banks and this plan involves expanding the station to 14 feeders. The two transformers at Malden TS were recently replaced, and there is additional capacity available at the station to meet the load requirement of the customer.

Based on a preliminary estimate the following will be the cost for the different layouts:

- Installation of two 28kV feeder breaker positions with feeder tie with underground feeder egress to outside station fence by 1 meter. Estimated cost of about $1.1M
- Installation of one 28kV feeder breaker position with no feeder tie with underground feeder egress to outside station fence by 1 meter. Estimated cost of about $875k
- Installation of one 28kV feeder breaker position with a break before make connection to alternate bus with underground feeder egress to outside station fence by 1 meter. Estimated cost of about $925k

8.1.2 Recommended Plan and/or Current Status

The above options have been provided to Essex Powerlines Corp. Hydro One is awaiting its decision on the preferred option expected to be made in 2016.

8.2 Tilbury TS Transformer End-of-Life Replacement

8.2.1 Description

Tilbury West HVDS and Tilbury TS are both supplied from 115 kV circuit K2Z and are adjacent to each other. The two stations supply the Town of Tilbury and surrounding area. Tilbury West HVDS consists of 2 x 15/20/25 MVA, 115/27.6 kV transformers of 1980's vintage with two feeder positions; and Tilbury TS consists of 1 x 6/8 MVA 115/27.6 kV transformer of 1950's vintage with one feeder position. The

2014 peak load at Tilbury TS was 1.0 MW, and 16 MW at Tilbury West HVDS. The future load levels over the next 10 years at these stations are not expected to grow significantly.

Tilbury TS is near its end-of-life, and a decision to replace or retire should be made by 2017. Following three options are under consideration for Tilbury TS:

(1) Transfer Tilbury TS load (M1 feeder) to Tilbury West DS and decommission Tilbury TS at a cost of about $1.7M. This option is feasible as there is sufficient capacity at Tilbury West HVDS to accommodate both the Tilbury West HVDS forecast load and the Tilbury TS forecast load into the long term. Further, Tilbury West HVDS has sufficient capacity to accommodate its existing DG connections plus the existing 5 MW solar DG currently connected to Tilbury TS.
(2) Refurbish Tilbury TS at a cost of about $5M. This option would retain the supply capacity level and supply diversity that currently exists.
(3) Build a new DESN station at Tilbury TS with dual 115kV circuit supply from the K2Z and K6Z for an expected cost of about $20M. This would include building the 115kV line out from Tilbury Junction to the TS and a complete new station.

8.2.2 Recommended Plan and Current Status

Option 1 is the least cost alternative. It is recommended that Hydro One will have further discussions with the LDCs regarding these options and associated costs. These discussions are expected in 2016, and a decision is expected to be made by no later than 2017. Project construction is planned to commence in 2018 for an expected in-service in 2019. Depending on the option selected, costs may have to be recovered from the LDCs consistent with the TSC.

8.3 Keith TS T1 Transformer End-of-Life Replacement

8.3.1 Description

Keith TS transformer T1 (25/33/42 MVA 115/27.6 kV) is of 1950's vintage and it is approaching end-of-life. EnWin is the only LDC supplied from this Keith T1 and exclusively serves a single customer Nemak. The peak load was 8 MW in 2014. The load growth is expected to remain at this level in the long-term.

There is sufficient capacity at the Keith DESN station to accommodate both the forecast at Keith DESN load plus the forecast Keith TS T1 load over the next 10 years.

Following three possible options are considered to address the end-of life issue for Keith TS T1:

(1) Replace Keith TS T1.
(2) Transfer Keith TS T1 load to Keith T22/T23 DESN station.
(3) Resupply Nemak from another EnWin feeder connected to Keith T22/T23 DESN.

8.3.2 Recommended Plan and Current Status

It is recommended to develop cost estimates for each of the option. Following that Hydro One will initiate discussions with EnWin to review the options and decide on a preferred option.

Cost estimates are expected in Q1 of 2016 and selection of a preferred option is expected before the end of 2016. Discussions will then ensue with Hydro One and EnWin regarding planned construction dates.

9. CONCLUSION

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE WINDSOR-ESSEX REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report provides a single consolidated source of information for infrastructure plans in the Windsor-Essex Region. It develops and outlines a plan for investments in transmission and/or distribution facilities to meet the electricity needs within the region. The RIP report was developed in collaboration of a Technical Working Group consisting of representation from the LDCs in the region, the IESO, and led by Hydro One consistent with the requirements set out in the TSC, DSC and the PPWG report.

This report highlights several near-term needs in the region for which implementation plans have already been developed and are planned for completion in the next five years. Table 9-1 provides a status of these projects along with their cost and timelines. Projects requiring further planning on scoping and pending decisions on the preferred alternative are provided in Table 9-2. Over the next five years, the total transmission and distribution investments associated with these projects is approximately $215M - $225M.

Table 9-1 Project Under Development

Project/Plan	Cost	I/S	Performed by
Supply to Essex County Transmission Reinforcement "SECTR TX"	$77.4 Million	March 2018	Hydro One
Supply to Essex County Transmission Reinforcement "SECTR DX"	$19.3 Million	March 2018 (first stage)	Hydro One Distribution
Replacement of Keith end-of-life autotransformers	$45 Million	2020	Hydro One
Replacement of Kingsville end-of-life transformers	$12 Million	2018	Hydro One
230kV/115kV circuit and 27.6kV feeder reconfiguration at Keith TS due to Gordie Howe International Bridge (GHIB) Project	$63 Million	October 2018	Hydro One
Transformer replacement and station refurbishment at Crawford TS	$8.46 Million	December 2016	Hydro One

Table 9-2 Project Pending Decision

Project/Plan	Cost	I/S	Performed by
Additional feeder position at Malden TS	TBD	TBD	Hydro One
Replacement of Tilbury end-of-life transformer	TBD	2019	Hydro One
Keith TS end-of-life T1 Transformer	TBD	TBD	Hydro One

There are no long-term needs in this region that requires plans to be developed at this time. As with any region, the Windsor-Essex Region is monitored as part of Hydro One and LDC operations. Should there be a need that emerges earlier due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

London Area

REGIONAL INFRASTRUCTURE PLAN

August 25th, 2017

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Organizations
Independent Electricity System Operator
Entegrus Inc.
Erie Thames Power Lines Corporation
London Hydro Inc.
St. Thomas Energy Inc.
Tillsonburg Hydro Inc.
Hydro One Networks Inc. (Distribution)

DISCLAIMER

This Regional Infrastructure Plan (“RIP”) report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be re-evaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, “the Authors”) make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared (“the Intended Third Parties”), or to any other third party reading or receiving the RIP report (“the Other Third Parties”), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN (“RIP”) WAS PREPARED BY HYDRO ONE NETWORKS INC. (“HYDRO ONE”) AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS OF THE LONDON AREA REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Entegrus Inc.
- Erie Thames Power Lines Corporation
- London Hydro Inc.
- St. Thomas Energy Inc.
- Tillsonburg Hydro Inc.
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the OEB’s mandated regional planning process for the London Area Region which consists of the Strathroy Sub-Region, Greater London Sub-Region, Woodstock Sub-Region, Aylmer-Tillsonburg Sub-Region, and the St. Thomas Sub-Region. It follows the completion of the London Area Region’s Needs Assessment (“NA”) in April 2015, the London Area Region Scoping Assessment (“SA”) in August 2015, the Strathroy TS Transformer Capacity Local Plan (“LP”) in September 2016, the Greater London Sub-Region Integrated Regional Resource Plan (“IRRP”) in January 2017, and the Woodstock Sub-Region Restoration Local Plan (“LP”) in May 2017.

This RIP provides a consolidated summary of needs and recommended plans for the entire London Area Region. Needs which are to be addressed include:

- Load restoration in Woodstock Sub-Region
- Load restoration in Greater London Sub-Region
- Voltage constraints, thermal constrains and delivery point performance in Aylmer-Tillsonburg Sub-Region

The major infrastructure investments planned for the region over the near and mid-term, as identified in the regional planning process are given below.

No.	Project	I/S Date	Estimated Cost[1]
1	Distribution System Upgrades in the Greater London Sub-Region	2023	$1.8-4M ($180/kW)
2	Wonderland TS Reinvestment: Replace transformer T5	2022	$15-20M

As per the Regional Planning process, the Regional Plan will be reviewed and/or updated at least once every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

[1] Costs presented are preliminary estimate and may change resulting from clarification of scope and through detailed cost estimating.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE LONDON AREA REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the study with input and consultation with Independent Electricity System Operator, Entegrus Inc., Erie Thames Power Lines Corporation, London Hydro Inc., St. Thomas Energy Inc., Tillsonburg Hydro Inc., and Hydro One Networks Inc. (Distribution) in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The London Area is located in South Western Ontario and includes all or part of the following Counties, and Cities: Oxford County, Middlesex County, Elgin County, Norfolk County, the City of Woodstock, the City of London, and the City of St. Thomas. For electricity planning purposes, the planning region is defined by electricity infrastructure boundaries, not municipal boundaries.

The region also includes the following First Nations: Chippewas of the Thames, Oneida Nation of the Thames, and Munsee-Delaware Nation.

Electrical supply to the London Area is provided through a network of 230 kV and 115 kV circuits supplied by 500/230 kV autotransformers at Longwood Transformer Station (TS) and 230/115 kV autotransformers at Buchanan TS and Karn TS. There are fifteen Hydro One step-down TS's, four direct transmission connected load customers and three transmission connected generators in the London Area. The distribution system consists of voltage levels 27.6 kV and 4.16kV.The boundaries of the Region are shown in Figure 1-1 below.

Within the current regional planning cycle, four regional assessments have been conducted for the London Area Region. The findings of these studies are an input to the RIP and the studies are as follows:

1. IESO's Greater London Sub-Region Integrated Regional Resource Plan – January, 2017
2. Hydro One's Woodstock Sub-Region Restoration Local Plan - May, 2017
3. Hydro One's Strathroy TS Transformer Capacity Local Plan – September, 2016
4. Hydro One's London Area Region Needs Assessment Report – April, 2015

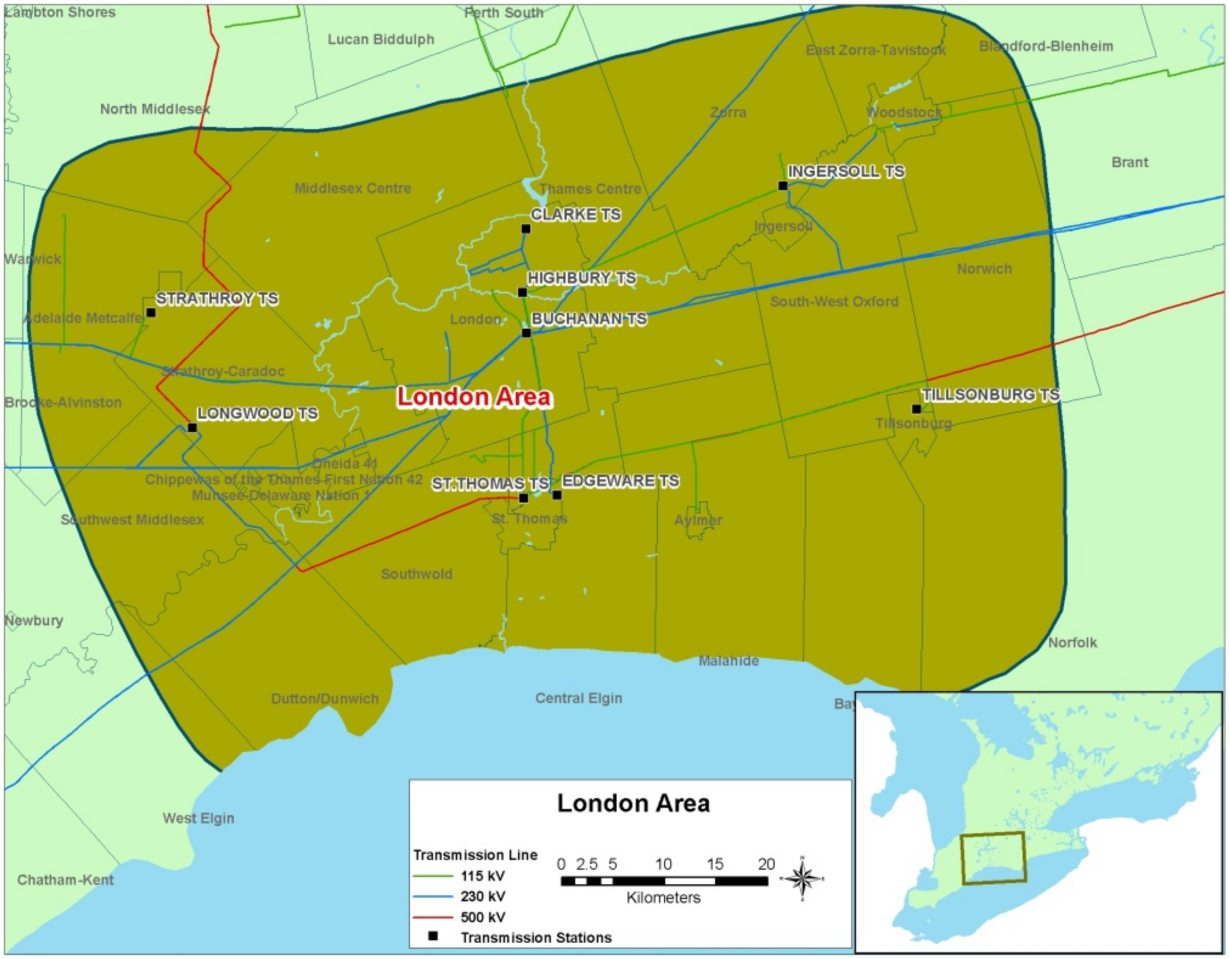

Figure 1-1 London Area Region

1.1 Scope and Objectives

This RIP report examines the needs in the London Area Region and its objectives are to:

- Confirm supply needs identified in previous planning phases;
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2016-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2016-2025 period and a wires plan to address them;
- Consideration of long-term needs identified in the Greater London Sub-Region IRRP

As per the Regional Planning process, the Regional Plan for the region will be reviewed and/or updated at least every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the regional characteristics
- Section 4 describes major High Voltage transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the regional needs
- Section 7 describes the needs and provides the alternatives and preferred solutions
- Section 8 provides the conclusion and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is performed at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning evaluates supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115kV and 230kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[2] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, and needs are local in nature, an assessment is undertaken for any necessary investments directly by the LDCs (or customers) and the transmitter through a Local Plan ("LP"). These needs are local in nature and can be best addressed by a straight forward wires solution. The Working Group recommends a LP undertaking when needs are a) local in nature b) limited to investments in wires (transmission or distribution) solutions c) do not require upstream transmission investments d) do not require plan level stakeholder engagement and e) do not require other approvals such as Leave to Construct (S92) approval or Environmental Approval.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. If there are needs that do not require regional coordination, the Working Group can recommend them to be undertaken as part of the LP approach discussed above. Otherwise, the approach is to complete either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-

[2] Also referred to as Needs Screening.

region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee ("LAC") in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

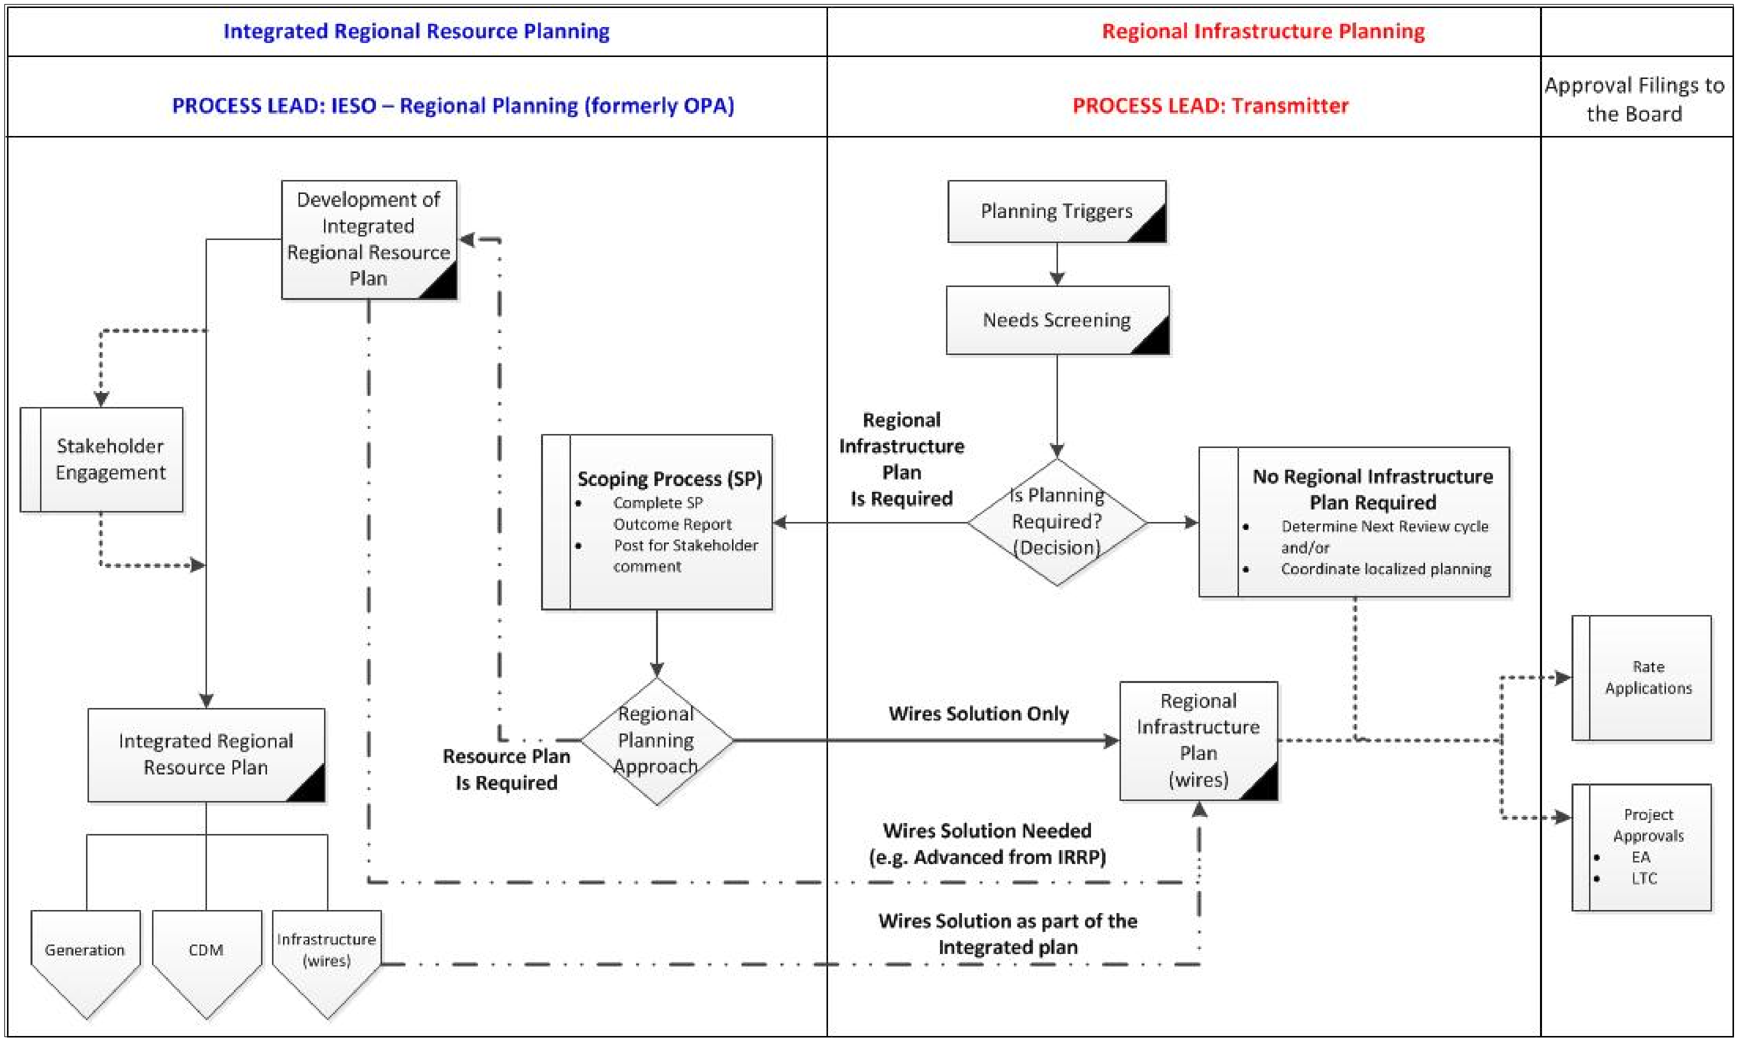

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects the following information and reviews it with the Working Group to reconfirm or update the information as required:

    - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation ("DG") or CDM programs;
    - Existing area network and capabilities including any bulk system power flow assumptions;
    - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

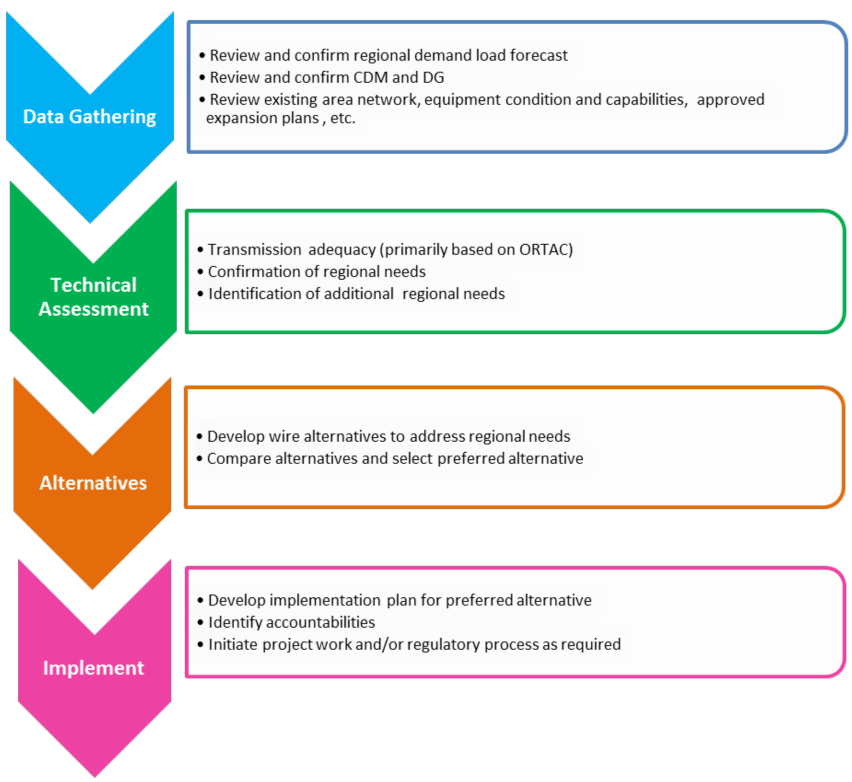

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE LONDON AREA IS LOCATED IN SOUTH WESTERN ONTARIO AND INCLUDES ALL OR PART OF OXFORD COUNTY, MIDDLESEX COUNTY, ELGIN COUNTY, NORFOLK COUNTY, THE CITY OF WOODSTOCK, THE CITY OF LONDON, AND THE CITY OF ST. THOMAS. THE REGION ALSO INCLUDES THE FOLLOWING FIRST NATIONS: CHIPPEWAS OF THE THAMES, ONEIDA NATION OF THE THAMES, AND MUNSEE-DELAWARE NATION. LONDON AREA REGION IS DIVIDED INTO FIVE SUB-REGIONS: STATHROY SUB-REGION, GREATER LONDON SUB-REGION, WOODSTOCK SUB-REGION, AYLMER-TILLSONBURG SUB-REGION, AND THE ST. THOMAS SUB-REGION.

Electrical supply to the London Area Region is provided through a network of 230 kV and 115 kV circuits supplied by 500/230 kV autotransformers at Longwood Transformer Station (TS) and 230/115 kV autotransformers at Buchanan TS and Karn TS. There are fifteen Hydro One step-down TS', four direct transmission connected load customers and three transmission connected generators. The region is summer-peaking and has a peak demand of approximately 1,250 MW including direct transmission connected customers. A map of the London Area Region (highlighting the sub-regions) and a single line diagram of the transmission system are shown in Figure 3-1 and Figure 3.2.

Table 3-1 Sub-Region Details

Sub-Region	Station Name (DESN)	Voltage Level (kV)	Supply Circuits	Connected Customers
Strathroy Sub-Region	Strathroy TS (T7/T8)	230/27.6	W2S, S2N	• Hydro One Distribution • Entegrus
	Longwood TS (T13/T14)	230/27.6	L24L, L26L	• Hydro One Distribution
Greater London Sub-Region	Talbot TS (T1/T2, T3/T4)	230/27.6	W36, W37	• London Hydro • Hydro One Distribution
	Clark TS (T3/T4)	230/27.6	W36, W37	
	Wonderland TS (T5/T6)	230/27.6	N21W, N22W	
	Buchanan TS (T13/T14)	230/27.6	W42L, W43L	
	Nelson TS (T1/T2)	115/13.8	W5N, W6NL	
	Highbury TS (T3/T4)	115/27.6	W6NL, W9L	
Woodstock Sub-Region	Ingersoll TS (T5/T6)	230/27.6	M31W, M32W	• Hydro One Distribution • Erie Thames Powerlines
	Woodstock TS (T1/T2)	115/27.6	K7, K12	
	Commerceway TS (T1/T2)	115/27.6	K7, K12	
Aylmer Sub-Region	Aylmer TS (T2/T3)	115/27.6	WT1A, W8T, T11T	• Hydro One Distribution, • Erie Thames Powerlines • Tillsonburg Hydro
	Tillsonburg TS (T1/T3)	115/27.6	WT1T, W8T, T11T	
St.Thomas Sub-Region	St. Thomas TS	115/27.6kV	W3T, W4T, T11T	Station is planned for decommissioning, no remaining customers connected.
	Edgeware TS	230/27.6kV	W45LS, W44LC	• Hydro One Distribution • St. Thomas Energy • London Hydro

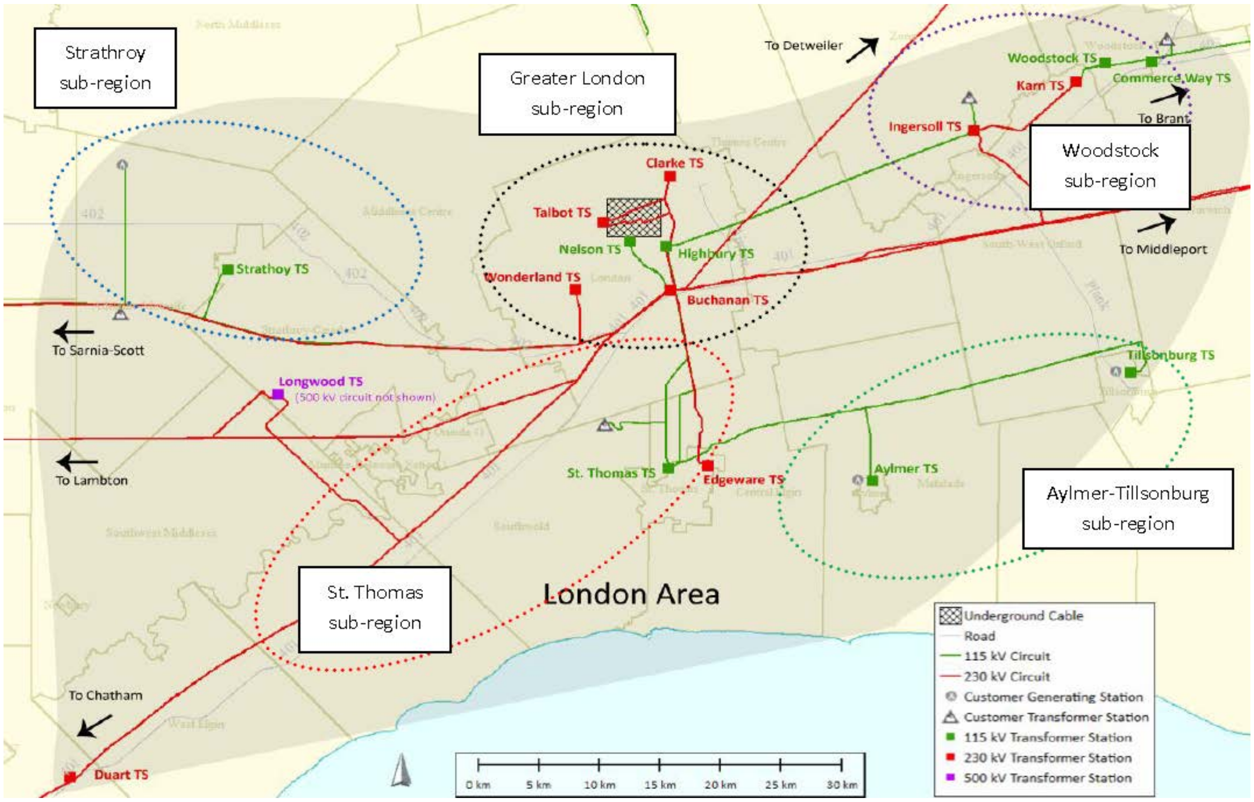

Figure 3-1 London Area Region – Supply Areas

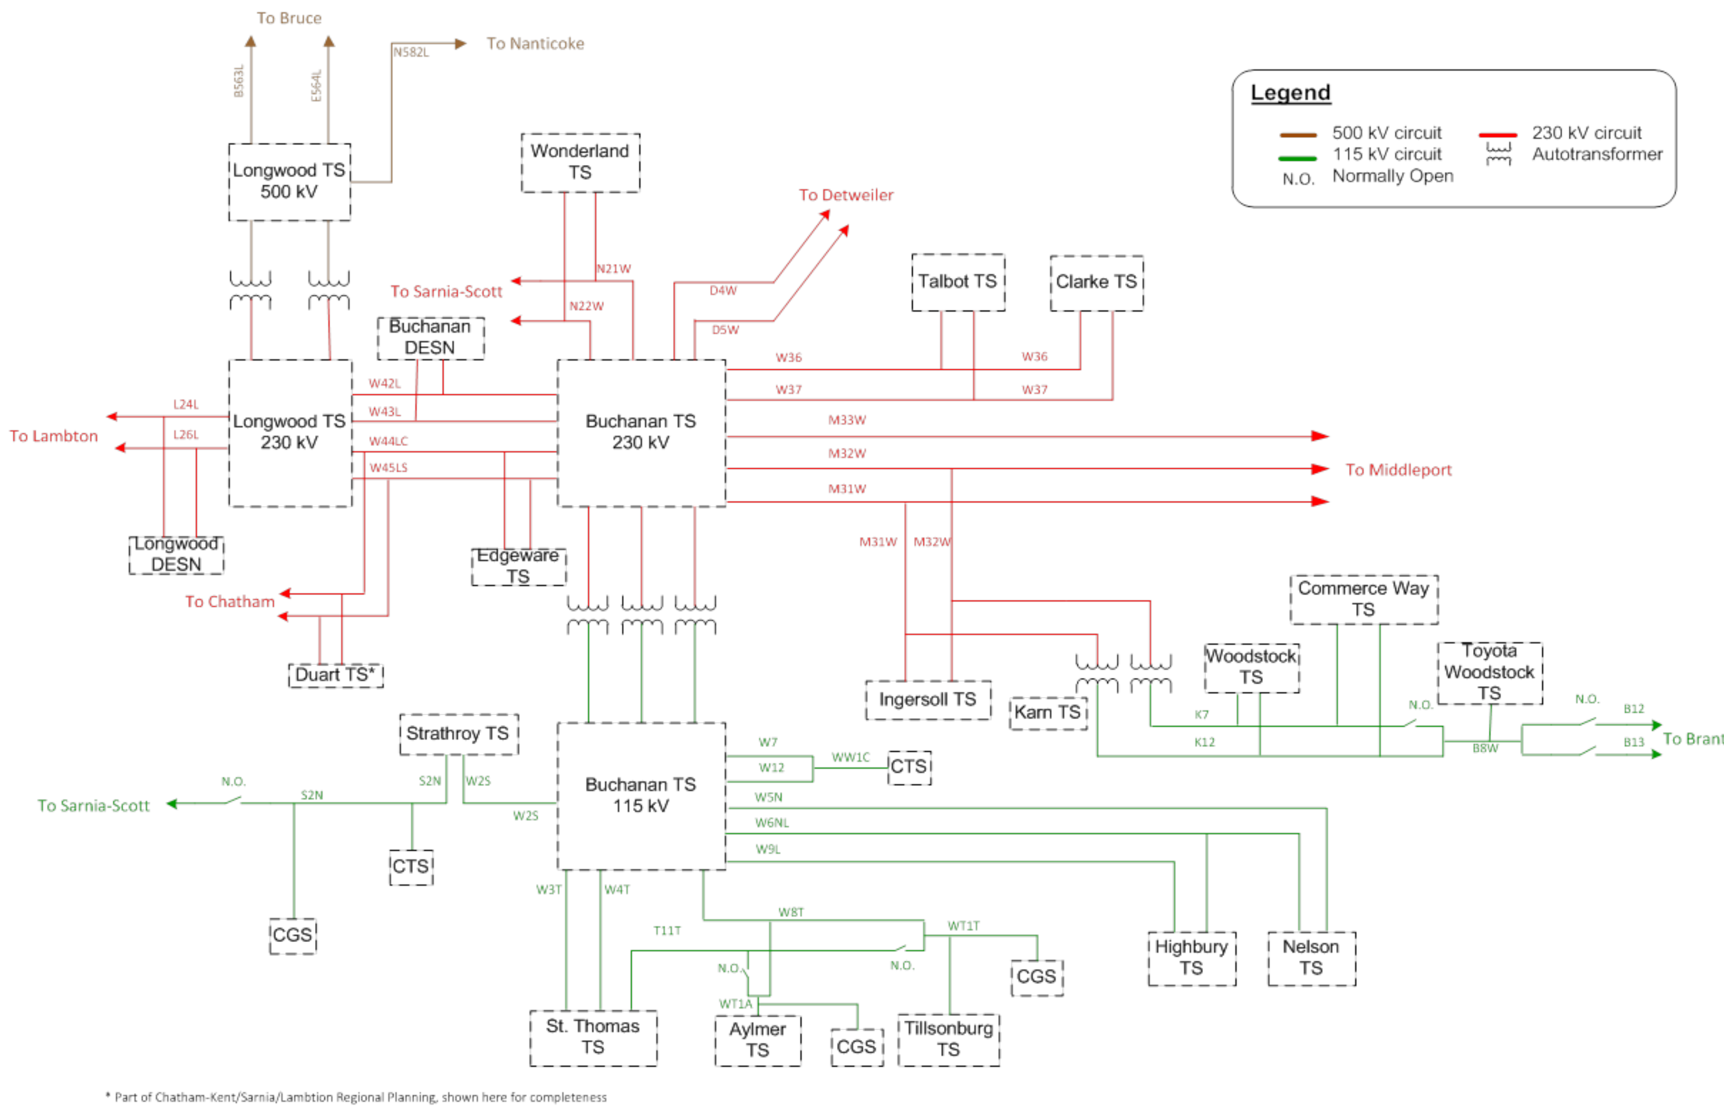

Figure 3-2 London Area Region Single Line Diagram

4. TRANSMISSION PROJECTS COMPLETED OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE LONDON AREA REGION.

A brief listing of the major projects completed over the last 10 years is given below:

- Talbot TS Expansion (2007) – Expansion of the existing Talbot TS and construction of a second 50/83 MVA 230/27.6 kV transformer station to alleviate load from existing transformer stations in the area, which were loaded beyond its capacity and provide additional capacity for the load growth in the London area.
- Highbury TS Transformer Replacement (2009) – Like-for-like replacement of 50/83 MVA 115/27.6 kV transformer T4 that was over 60 years old and nearing end-of-life.
- Commerce Way TS (2010) – Construction of a new 50/83 MVA 115/27.6 kV Commerce Way transformer station to alleviate load from Woodstock TS, which was loaded beyond its capacity and provide additional capacity for the load growth in the Woodstock area.
- Strathroy TS Transformer Replacement (2012) – Like-for-like replacement of 25/42 MVA 115/27.6 kV transformer T2 due to failure.
- Ingersoll TS Transformer Replacement (2012) – Like-for-like replacement of 75/125 MVA 230/27.6 kV transformers T5 & T6 that were approximately 35 years old. The transformers were identified to have a design weakness and were replaced to mitigate the risk of failures, improve restoration time and maintain system performance.
- Woodstock TS Transformer Replacement (2014) – Like-for-like replacement of 50/83 MVA 115/27.6 kV transformers T1 & T2 that were approximately 50 years old and were nearing end-of-life.

The following development projects are expected to be placed in-service within the next 10 years:

1. **Aylmer TS**: is located in Southwestern Ontario and is comprised of two 11/15 MVA, 110-28 kV transformers (T2 & T3) and two 27.6 kV feeder breaker positions M1, M2. The station is supplied by a single 115kV line WT1A and it supplies Erie Thames Powerlines Corp. and Hydro One Distribution at 27.6 kV.

   The deteriorating asset condition of a significant portion of station equipment, including transformers (T2 & T3) and LV switchyard, qualifies it as a candidate for a complete station rebuild. To address the urgent need, the existing station will be replaced with a new DESN with two 25/33/42 MVA transformers. The replacement work also includes all 28kV LV switching facilities, the addition of two new feeder positions, and an upgrade to associated protection and control systems.

   This project is currently under execution and planned to be completed before end of 2017.

2. **Strathroy TS**: is located in Middlesex County in Southwestern Ontario and is comprised of two 25/33/42 MVA 110-28 kV transformers (T1 & T2) and four 27.6 kV feeder breaker positions. Strathroy TS supplies Entegrus Powerlines Inc. and Hydro One Distribution at 27.6 kV.

   Due to deteriorating asset condition, Hydro One has planned to replace the T1 transformer with similar type 42MVA transformer, replace all LV switching facilities, and upgrade associated protection and control facilities and AC/DC station ancillary infrastructure.

   This project is currently under execution and planned to be completed in 2017.

3. **Nelson TS**: is located in the City of London in Southwestern Ontario and is comprised of two DESN stations (the "T1/T2 DESN" and the "T3/T4 DESN") which are both supplied from the 115 kV circuits W5N and W6NL. The T1/T2 DESN consists of two 18/27/33 MVA, 115/ 13.8 kV transformers with two LV yards (outdoor and indoor), and the T3/T4 DESN consists of two 60/80/100 MVA, 115/ 13.8 kV transformers with two LV yards (both indoor). The T1/T2 DESN supplies about 17 MW of 13.8kV load in the London downtown area and the T3/T4 DESN supplies approximately 31 MW of 13.8 kV load, also in the London downtown area.

   The deteriorating asset condition of a significant portion of station equipment, including transformers (T1 & T2) and LV switchyard, qualifies it as a candidate for a complete station rebuild. In addition, London Hydro has requested that Hydro One rebuild the LV at 27.6kV rather than at 13.8kV so that the station can be integrated into London Hydro's 27.6kV distribution system to provide load support. As a result, Hydro one is building a new station within the existing Nelson TS yard. The new station will consist of two new 115/27.6 kV, 50/83 MVA DESNs and new LV switchyard with 8 feeder positions and 2 capacitor bank positions. All associated protection and control systems and station ancillary infrastructure will be upgraded. The work will also involve decommissioning of the existing DESN substation consisting of T1 and T2 transformers and the 13.8kV air insulated outdoor switchyard.

   This project is currently under execution and planned to be completed in 2018.

5. FORECAST AND STUDY ASSUMPTIONS

THE FORECASTS REFLECT THE EXPECTED PEAK DEMAND AT EACH STATION UNDER EXTREME WEATHER CONDITIONS, BASED ON FACTORS SUCH AS POPULATION, HOUSEHOLD AND ECONOMIC GROWTH, CONSISTENT WITH MUNICIPAL PLANNING ASSUMPTIONS.

5.1 Historical Demand

The London Area regional peak load has been relatively constant over the past 5 years (approximate decline of -0.4%).

5.2 Contribution of CDM and DG

In developing the planning forecast, the following process was used to assess the London Region:

- First, "gross demand" is established. Gross demand reflects the forecast developed and provided by the area LDCs and is influenced by a number of factors such as economic, household and population growth.
- Second, "net demand" is derived by reducing the gross demand by expected savings from improved building codes and equipment standards, customer response to time-of-use pricing, projected province-wide CDM programs, committed and forecast DG . This information is provided by the IESO.

5.3 Gross and Net Demand Forecast

Prior to the RIP's kick-off, the Working Group was asked to confirm the load forecasts for all stations in the Region provided for previous assessments. The RIP's load forecast was updated according the revised load forecasts provided by the LDCs.

The load in the London Area Region including CDM targets and DG contributions is expected to remain relatively constant over the study period (approximate growth rate of -0.3%). The growth rate varies across the region but an overall coincident net load forecast in the region is illustrated in Figure 5-1. The gross and net non-coincident and coincident load forecast, adjusted for extreme weather, CDM, and DG, for each station in the region are provided in Appendix B and C.

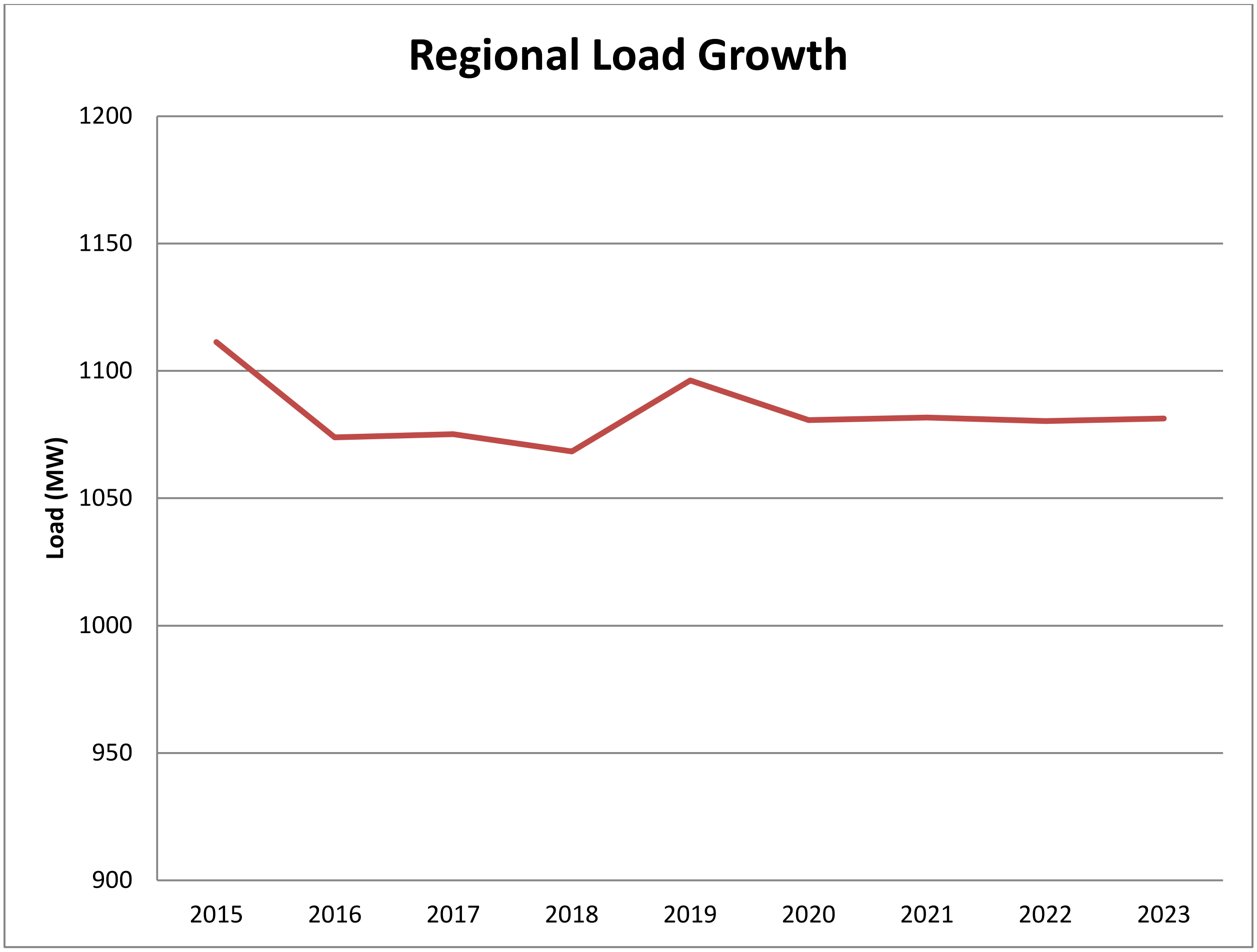

Figure 5-1 London Area Region Coincident Net Load Forecast

5.4 Other Study Assumptions

Further assumptions are as follows:

- The study period for the RIP assessment is 2016 – 2023.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on extreme summer peak loads.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this region is determined by the summer 10-Day Limited Time Rating ("LTR").

6. ADEQUACY OF FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND STEP DOWN TRANSFORMATION STATION FACILITIES SUPPLYING THE LONDON AREA REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM PERIOD.

Within the current regional planning cycle, four regional assessments have been conducted for the London Area Region. The findings of these studies are an input to the RIP and the studies are as follows:

1. IESO's Greater London Sub-Region Integrated Regional Resource Plan – January, 2017[1]
2. Hydro One's Woodstock Sub-Region Restoration Local Plan - May, 2017[2]
3. Hydro One's Strathroy TS Transformer Capacity Local Plan – September, 2016[3]
4. Hydro One's London Area Region Needs Assessment Report – April, 2015[4]

The IRRP, NA, and LP studies identified a number of regional needs based on the forecast load demand over the near to mid-term. Based on the regional growth rate referred to in Section 5, this RIP reviewed the loading on transmission lines and stations in the London Area Region assuming the new Nelson TS DESN will be in-service by the end of 2018, and the new Aylmer TS DESN will be in-service by the end of 2017. Further detailed description and status of plans to meet these needs is provided in Section 7.

6.1 Transmission Line Facilities

Electrical supply to the London Area is provided through a network of 230 kV and 115 kV circuits supplied by 500/230 kV autotransformers at Longwood Transformer Station (TS) and 230/115 kV autotransformers at Buchanan TS and Karn TS. The main features of the electrical supply system in the London Area are as follows:

- Longwood TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230 kV autotransformers.
- Buchanan TS and Karn TS are the transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.
- Fifteen step-down transformer stations supply the London Area load: Aylmer TS, Buchanan TS, Clarke TS, Commerceway TS, Edgeware TS, Highbury TS, Ingersoll TS, Longwood TS, Nelson TS, Strathroy TS, St. Thomas TS, Talbot TS, Tillsonburg TS, Wonderland TS, and Woodstock TS.
- Four Customer Transformer Stations (CTS) are supplied in the London Area: Ford Talbotville CTS, Enbridge Keyser CTS, Lafarge Woodstock CTS, and Toyota Woodstock CTS.
- There are 3 existing transmission connected generating stations in the London Area as follows:

- Suncor Adelaide GS is a 40 MW wind farm connected to 115 kV circuit west of Strathroy TS
- Erie Shores Wind Farm GS is a 99 MW wind farm connected to 115kV circuit near Tillsonburg TS
- Silver Creek GS is a 10 MW solar generator connected to 115kV circuit near Aylmer TS

The 500kV system is part of the bulk system planning conducted by the IESO and is not studied as part of this RIP

Table 6-1 provides 230 kV and 115 kV circuit network that supplies to the London Area.

Table 6-1 230 kV and 115 kV circuits network in the London Area

Voltage	Circuit Designations	Location
230 kV	N21W, N22W	Scott TS to Buchanan TS
	W42L, W43L	Longwood TS to Buchanan TS
	W44LC	Longwood TS to Chatham TS to Buchanan TS
	W45LS	Longwood TS to Spence SS to Buchanan TS
	W36, W37	Buchanan TS to Talbot TS
	D4W, D5W	Buchanan TS to Detweiler TS
	M31W, M32W	Buchanan TS to Ingersoll TS to Middleport TS
	M33W	Buchanan TS to Brantford TS
115 kV	W2S	Buchanan TS to Strathroy TS
	W5N	Buchanan TS to Nelson TS
	W6NL	Buchanan TS to Highbury TS to Nelson TS
	W9L	Buchanan TS to Highbury TS
	W7, W12 WW1C W8T T11T WT1T W3T, W4T WT1A K7, K12	Buchanan TS to CTS Buchanan TS to CTS Buchanan TS to Cranberry JCT Erie Shore Wind Farm JCT to Tillsonburg TS Buchanan TS to St. Thomas TS Aylmer TS to Lyons JCT Karn TS to Commerce Way TS

The 115 kV circuit W8T from Buchanan TS to Edgeware JCT exceeds its planning rating under pre-contingency conditions in the near term based on the gross load forecast. Such thermal overload is deferred to the medium term based on the net load forecast. The transmission line constraint is further described in section 7.2.2 of this report. The remaining 115 kV and 230 kV circuits supplying the London Area are adequate over the study period for the loss of a single element in the area.

6.2 Step-Down Transformation Facilities

There are a total of fifteen step-down transmission connected transformer stations in the London Area Region. The stations have been grouped based on the geographical area and supply configuration. The station loading and the associated station capacity and the need date in each sub-region is provided in Table 6-3 below. The findings of the transformation capacity assessment are as follows:

- As confirmed in the “Strathroy TS Transformer Capacity Local Plan (LP)”, based on the limited time rating (“LTR”) of the station, the transformation capacity is adequate in Strathroy Sub-Region over the study period.
- As confirmed in the “Greater London Sub-Region Integrated Regional Resource Plan (IRRP)”, based on the LTR of the stations, the transformation capacity is adequate in Greater London Sub-Region over the study period.
- Based on the LTR of the load stations, the transformation capacity is adequate in Woodstock Sub-Region, Aylmer-Tillsonburg Sub-Region and the St. Thomas Sub-Region over the study period.

Table 6-2 Transformation Capacities in the Sub-Regions

Sub-Region	Station	LTR (MW)	2015 Non Coincident Peak (MW)	Need Date
Strathroy Sub-Region	Strathroy TS	50	45	-[3]
	Longwood TS	128	33	-[3]
Greater London Sub-Region	Talbot TS	290	268	-[3]
	Clark TS	110	106	-[3]
	Wonderland TS	99	109[4]	-[3]
	Buchanan TS	183	143	-[3]
	Nelson TS	105[5]	23	-[3]
	Highbury TS	114	93	-[3]
Woodstock Sub-Region	Ingersoll TS	167	75	-[3]
	Woodstock TS	87	56	-[3]
	Commerceway TS	112	33	-[3]
Aylmer Sub-Region	Aylmer TS	55[6]	21	-[3]
	Tillsonburg TS	109	88	-[3]
St.Thomas Sub-Region	St.Thomas TS	50	0	-[3]
	Edgeware TS	191	113	-[3]

[3] Adequate over the study period
[4] Peak loading at Wonderland TS is forecasted to reduce to within its 10-day LTR rating by 2017
[5] Nelson TS LTR reflects the Station Rebuild Project under execution - planned to be completed in 2018
[6] Aylmer TS LTR reflects the Transformer Replacement Project under execution - planned to be completed in 2017

The non-coincident and coincident load forecast for all stations in the Region is given in Appendix C and Appendix D, respectively.

6.3 System Reliability and Load Restoration

In case of incidents on the transmission system, ORTAC provides the load restoration requirements relative to the amount of load affected. Planned system configuration must not exceed 600 MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

In the London Area Region it is expected that all loads can be restored within the ORTAC load restoration requirements with exception of:

- Loss of M31W/M32W – Woodstock Sub-Region
- Loss of W36/W37 or W42L/W43L – Greater London Sub-Region

The load restoration constraints are further described in section 7.1 of this report.

6.4 Voltage

Under pre-contingency conditions with all facilities in service, ORTAC provides requirements for acceptable system voltages. The table below indicates the maximum and minimum voltages generally applicable. These values are obtained from Chapter 4 of the IESO "Market Rules" and CSA standards for distribution voltages below 50 kV.

Table 6-3 Pre-Contingency Voltage Limits

Nominal Bus Voltage (kV)	500	230	115	Transformer Station Low Voltage Bus
Maximum Continuous (kV)	550	250	127*	106%
Minimum Continuous (kV)	490	220	113	98%

*Certain buses can be assigned specific maximum and minimum voltages as required for operations. In northern Ontario, the maximum continuous voltage for the 115 kV system can be as high as 132 kV.

With all planned facilities in service pre-contingency, ORTAC provides requirements for system voltage changes in the period immediately following a contingency as indicated in Table 6-4.

Table 6-4 Post-Contingency Voltage Change Limits

Nominal Bus Voltage (kV)	500	230	115	Transformer Station Low Voltage Bus		
				44	27.6	13.8
% voltage change **before** tap changer action	10%	10%	10%	10%		
% voltage change **after** tap changer action	10%	10%	10%	5%		
AND within the range						
Maximum* (kV)	550	250	127	112% of nominal		
Minimum* (kV)	470	207	108	88% of nominal		

*The maximum and minimum voltage ranges are applicable following a contingency. After the system is re-dispatched and generation and power flows are adjusted the system must return to within the maximum and minimum continuous voltages.

The Aylmer-Tillsonburg Sub-Region is normally supplied by a single 115 kV transmission circuit W8T which is approximately 60 km in length. The Sub-Region has a total peak demand of 106 MW and is expected to grow to 122 MW by year 2023. During planned or forced outages the interrupted load in the Sub-Region can be transferred to the backup 115 kV circuit T11T.

Under pre-contingency conditions and with Erie Shores Wind Farm unavailable, the voltage at Tillsonburg TS 115 kV bus does not meet ORTAC criteria (113 kV) under existing peak load conditions and may reach as low as 100 kV. The transformer ULTCs at Tillsonburg TS is however maintaining the LV bus voltage above ORTAC criteria of 27 kV (98% of nominal voltage). Study results indicate that the LV voltage cannot be maintained at desirable levels when the load in the Aylmer-Tillsonburg Sub-Region exceeds 115 MW. Based on the latest load forecasts, this loading level may be reached as early as 2019.

The voltage constraint is further described in section 7.2.1 of this report.

6.5 Customer Delivery Point Performance

In accordance with Section 2.5 of the Transmission System Code, Hydro One Networks Inc. (Networks) is required to develop performance standards at the customer delivery point level, consistent with system wide standards that reflect:

- typical transmission-system configurations that take into account the historical development of the transmission system at the customer delivery point level;
- historical performance at the customer delivery point level;
- acceptable bands of performance at the customer delivery point level for the transmission system configurations; geographic area, load, and capacity levels; and

- defined triggers that would initiate technical and financial evaluations by the transmitter and its customers regarding performance standards at the customer delivery point level, exemptions from such standards, and study triggers and results.

The Customer Delivery Point Performance Standards and triggers are based on the size of load being served (as measured in megawatts by a delivery point's total average station load) are provided in Table 6-4 below.

Table 6-4 Customer Delivery Point Performance Standards

Performance Measure	Delivery Point Performance Standards *(Based on a Delivery Point's Total Average Station Load)*							
	0-15 MW		**15-40 MW**		**40-80 MW**		**>80 MW**	
	Standard (Average Performance)	Minimum Standard of Performance	Standard (Average Performance)	Minimum Standard of Performance	Standard (Average Performance)	Minimum Standard of Performance	Standard (Average Performance)	Minimum Standard of Performance
DP Frequency of Interruptions (Outages/year)	4.1	**9.0**	1.1	**3.5**	0.5	**1.5**	0.3	**1.0**
DP Interruption Duration (min/year)	89	**360**	22	**140**	11	**55**	5	**25**

The minimum standards of performance are to be used as triggers by Networks to initiate technical and financial evaluations with affected customers. These bands are to:

- accommodate normal year-to-year delivery point performance variations;
- limit the number of delivery points that are to be considered "performance outliers" to a manageable/affordable level;
- deliver a level of reliability that is commensurate with customer value i.e. the larger the load, the greater the level of reliability provided; and
- direct/focus efforts for reliability improvements at the "worst" performing delivery points.

The customer delivery points serving THI and HONI distribution at Tillsonburg TS is not meeting CDPPS requirements with regards to frequency of interruptions. This customer delivery point has averaged approximately 3.3 interruptions per year over the past 10 years, doubling the performance target of 1.5.

The Customer Delivery Point Performance need is further described in section 7.2.3 of this report.

6.6 End-of-Life Equipment Replacements

Recent condition assessment of Wonderland TS has revealed that one of the existing power transformers at the station (T5) is in poor condition and must be replaced in the near-term. The facility was originally built in the 1960s and its assets are degrading in condition and require replacement by 2022. The existing 230/28kV T6 power transformer was replaced in 2004 due to failure. The existing 230/28 kV T5 power transformer will be replaced with a similar unit (230kV-28kV 83 MVA) to match the ratings of transformer T6. After the transformer replacement is completed, the LTR of Wonderland TS is expected to increase to approximately 114MW.

7. REGIONAL NEEDS & PLANS

THIS SECTION DISCUSSES THE ELECTRICAL INFRASTRUCTURE NEEDS, POSSIBLE WIRES ALTERNATIVES AND SUMMARIZES THE CURRENT PREFERRED WIRES SOLUTION FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS IN THE LONDON AREA REGION

The needs listed in Table 7-1 include needs previously identified in the IRRP for the Greater London Sub-Region and the NA and LP's for the Strathroy, Woodstock, Aylmer-Tillsonburg and St. Thomas Sub-Regions.

The near-term needs include needs that arise over the first five years of the study period (2016 to 2020) and the mid-term needs cover the second half of the study period (2021-2025).

Table 7-1 Identified Near-Term Needs in London Region

Sub-Region	Type	Section	Needs	Timing
Woodstock Sub-Region	Load Restoration	7.1.1	Loss of M31W/M32W	No action required at this time
Greater London Sub-Region		7.1.2	Loss of W36/W37 or W42L/W43L	Now

	Delivery Point Performance	7.2.3	Poor delivery point performance at Tillsonburg TS	Now

7.1 Load Restoration

7.1.1 Woodstock Sub-Region: Loss of M31W/M32W

Description

The Woodstock Sub-Region load restoration need was identified in the NA and LP reports and further assessment was recommended to address the supply shortfall during peak load periods. Previous assessments indicated that in case of loss of two transmission elements (M31W/M32W), the load interrupted with current circuit configuration during peak periods may exceed load restoration criteria.

Recommended Plan and Current Status

A local planning report[7] was completed to develop a plan to address the load restoration need identified in the Sub-Region. The report concluded the following:

For Woodstock Sub-Region, the critical line section is M31W/M32W tap between Salford Junction and Ingersoll Junction. Should a contingency on this line section occur, all of the sub-region's load, which amounted to 188 MW in 2016, would be interrupted by configuration.

Under such emergency conditions, depending on system performance and availability of switching facilities, all or a portion of a load station could be restored by transferring load to neighbouring unaffected supply. Hydro One Distribution estimated that 10 MW of load at Ingersoll TS could be transferred to Highbury TS. Another 8 MW could be transferred from Commerce Way TS to Tillsonburg TS on the feeder level. On the transmission side, the supply from Brant TS will be able to restore about 20 MW of load in the Woodstock Sub-Region.

These measures can be deployed remotely to manage and mitigate the impact of the loss of two transmission elements within the 4 hours timeframe. To restore the remaining 150 MW of interrupted load within 8 hours, field crews from the nearest staffed centre in London Area will be dispatched to install temporary fixes on the transmission system such as building an emergency by-pass.

The Working Group is recommending that no further action is required at this time.

7.1.2 Greater London Sub-Region: Loss of W36/W37 or W24L/W43L

The Greater London Sub-Region load restoration need was identified in the NA and IRRP reports and further assessment was recommended to address the supply shortfall during peak load periods. Previous assessments indicated that for the loss of two transmission elements (W36/W37 or W42L/W43L), the load interrupted with the current circuit configuration during peak periods may exceed load restoration criteria.

W36/W37 – Clarke TS and Talbot TS

Description

Clarke TS and Talbot TS are supplied by 230 kV transmission circuits W36/W37 and have a total peak demand of 370 MW. Following the loss of both W36 and W37, supply to Clarke TS and Talbot TS would be interrupted.

[7] Woodstock Restoration Local Planning Report – May 30, 2017

Under such emergency conditions, London Hydro can currently restore up to 55 MW of interrupted load through distribution system transfers within 30 minutes and up to 105 MW within four hours. The interrupted load would be transferred to Wonderland TS, Buchanan TS and Highbury TS during such events. As part of the rebuild of Nelson TS in 2018, the station's LV bus will be converted from 13.8 kV to 27.6 kV. After the conversion, Nelson TS will be able to provide additional backup capacity to support meeting the ORTAC timelines in the event of a double circuit outage. With the new 27.6 kV Nelson TS, a total of 95 MW of load can be restored within 30 minutes, and 150 MW of load within four hours. This reduces the 30 minute shortfall to 25 MW and the four hour shortfall to 71 MW in 2019.

Recommended Plan and Current Status

The Greater London Sub-Region IRRP [8] developed a plan to address the load restoration need identified in the Sub-Region. The report concluded the following:

Currently, London Hydro has 28 distribution feeders in total that emanate from Clarke TS and Talbot TS. Only half of these feeders are presently interconnected to other non-Clarke and non-Talbot feeders (i.e., Highbury, Buchanan, and Wonderland TS feeders). Installing approximately 10 additional automated switching devices in strategic locations on the distribution feeders could provide an additional 25 MW of load transfer capability within 30 minutes for Clarke TS and Talbot TS load. These switching devices are estimated to cost approximately $0.6 million.

An additional 10-15 MW of load restoration support for longer-term relief (more than 30 minutes) could be provided by extending the 14 existing Clarke and Talbot feeders to connect with feeders from non-connected neighboring stations. For example, a 3.7 km Talbot feeder line extension to connect to a Wonderland feeder at an approximate cost of $1.2 million could provide support to 10-15 MW of load for the Clarke TS and Talbot TS load pockets.

For a unit cost of $180/kW, the Working Group is recommending the implementation of automated switching devices and feeder extensions on the Distribution System as the most cost effective method to substantially mitigate the restoration shortfall in this area.

These solutions would also maximize the use of existing distribution infrastructure and provide flexibility to London Hydro to manage load between different stations in its service territory.

It is important to note that the feeder capacity margins are not static and will reduce as the 20-year projected load growth at the transformer stations materializes. Hence, the amount of load that can be restored using the distribution system in the event of a double element loss of supply to Clarke TS and Talbot TS will reduce over time. Consequently, part of the recommendation is that London Hydro continues to monitor load growth and relevant feeder limits in its service territory. The Working Group recommends the actions described below to meet the restoration need identified for the Greater London

[8] Greater London Sub-Region, Integrated Regional Resource Plan – January 20, 2017

Sub-region. Successful implementation of this plan will substantially address the restoration need in this sub-region for the next decade.

W42L/W43L – Buchanan TS

In case of loss of theW42L/W43L transmission lines, the load supplied from Buchanan TS which reaches slightly over 150 MW would be interrupted by configuration.

Under such emergency conditions, London Hydro can transfer any interrupted load in excess of 150 MW to adjacent stations within the service area. These measures to manage and mitigate the impact of the equipment loss can be deployed within the 4 hours timeframe. To restore the remaining 150 MW of interrupted load within 8 hours, field crews from the nearest staffed centre in London area will be dispatched to install temporary fixes on the transmission system such as building an emergency by-pass.

The Working Group is recommending that no further action is required at this time.

7.2 Aylmer-Tillsonburg Sub-Region: Voltage/Thermal Constraint & Delivery Point Performance

The Aylmer-Tillsonburg Sub-Region is primarily supplied by a single 115 kV transmission circuit W8T. The Sub-Region has a total peak demand of 106 MW and is expected to grow to 122 MW by year 2023. During planned or forced outages the interrupted load in the Sub-Region can be transferred to the backup 115 kV circuit T11T. The Tillsonburg TS voltage constraint and the W8T thermal constraint need was identified in the NA report and further assessment was recommended to address these needs. Following the NA report, the Working Group further identified Delivery Point Performance needs at Tillsonburg TS. These needs are assessed as part of this RIP.

7.2.1 Voltage Constraint

The voltage constraint observed on the 115 kV bus at Tillsonburg TS results from having a long 65 km 115 kV single circuit supply, a large 90 MW Tillsonburg TS load at the end of the transmission line, and a lack of reactive power support at the station to compensate. To mitigate the voltage constraints at Tillsonburg TS, the Working Group considered the following options.

Installation of Shunt Capacitors at Tillsonburg TS

One method to mitigate the voltage constraints at Tillsonburg TS is to provide reactive power compensation at the station. Installation of shunt capacitor banks (2 x 21 Mvar) on the 27.6 kV bus at Tillsonburg TS provides the necessary reactive compensation to meet the ORTAC voltage criteria (113 kV) for the peak load forecast over the study period of 89 MW at Tillsonburg TS. Further, the shunt capacitors are capable of supporting future load growth beyond the study period up to 109 MW – equal to the LTR rating of Tillsonburg TS. These shunt capacitor banks are estimated to cost approximately $8 million.

Installation of Switching at Buchanan TS and Reconfiguration of 115 kV Circuits

Another method to mitigate the voltage constraints at Tillsonburg TS is to reconfigure the 115 kV circuits supplying the Aylmer-Tillsonburg Sub-Region. A single line diagram of the Aylmer-Tillsonburg Sub-Region after the decommissioning of St. Thomas TS is shown in Figure 7-1.

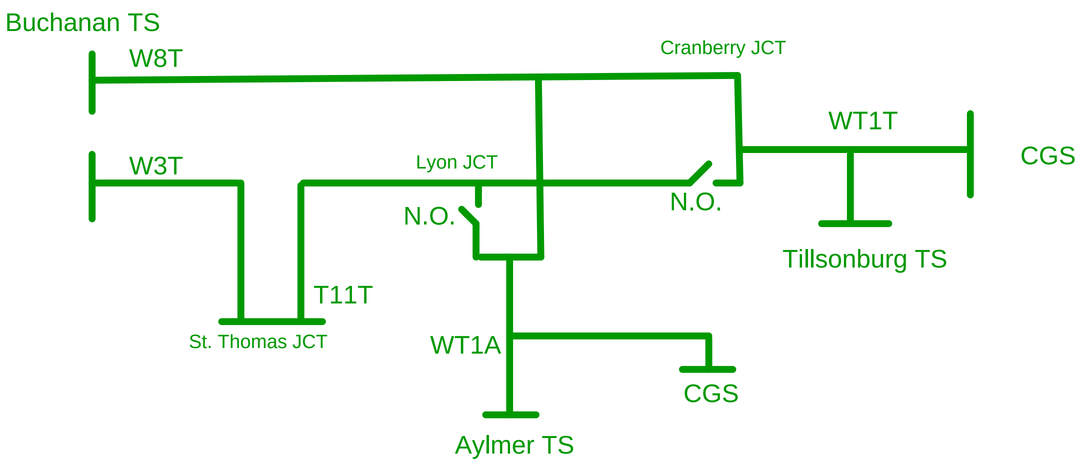

Figure 7-1 Existing Single Line Diagram of Aylmer-Tillsonburg Sub-Region

Aylmer TS and Tillsonburg TS are normally supplied by 115 kV circuit W8T. Reconfiguring the system so that Aylmer TS and Tillsonburg TS are normally supplied by both W8T and T11T reduces the system impedance and improves the voltages in the area. The reconfiguration of the 115 kV system requires installing new switches at Buchanan TS to tie 115 kV circuits W8T and W3T. The "normally open" switches at Lyon JCT and Cranberry JCT will be changed to "normally closed". Lastly the protection relaying at Buchanan TS will require upgrades/modification. A single line diagram of the Aylmer-Tillsonburg Sub-Region after the reconfiguration is shown in Figure 7-2.

The voltages at the Tillsonburg TS 115 kV bus after the reconfiguration improve to 113 kV, meeting the ORTAC voltage criteria for the peak load forecast over the study period. Any further load growth beyond the peak load forecast of 89 MW at Tillsonburg TS will cause the voltage at Tillsonburg TS 115 kV bus to fall below the ORTAC voltage criteria of 113 kV. Similar to the current situation, the transformer ULTCs at Tillsonburg TS can maintain the LV bus voltage above the ORTAC criteria of 27 kV (98% of nominal voltage) for load growth up to 109 MW – equal to the LTR rating of Tillsonburg TS. Reconfiguration of the 115 kV system is estimated to cost approximately $4 million.

While the reconfiguration of the 115 kV system mitigates the voltage constraint need over the study period, it potentially worsens the customer delivery point performance of Tillsonburg Hydro and Hydro One Distribution at Tillsonburg TS. Frequency of outages is expected to increase slightly resulting from higher exposure to lightning and wind events. In addition, restoration times are expected to increase slightly due to the incremental switching requirements.

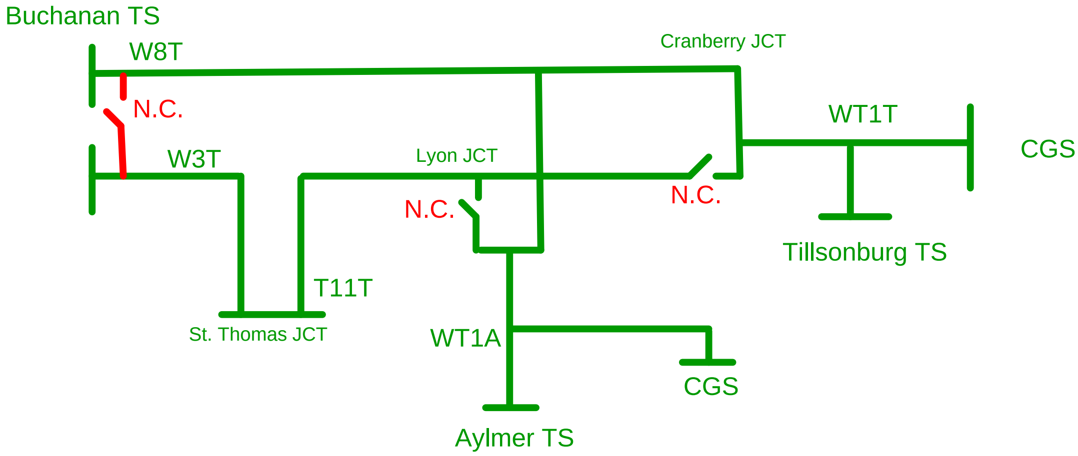

Figure 7-2 Single Line Diagram of Aylmer-Tillsonburg Sub-Region after Reconfiguration

7.2.2 Thermal Constraint

Thermal constraints are observed on a section of line approximately 1.5 km long on 115 kV circuit W8T between Buchanan TS and Edgeware JCT. Under pre-contingency conditions, the thermal loading on this section line reaches 140% of its planning rating of 590A based on the peak load forecast over the study period. Implementing either one of the options in section 7.2.1 to mitigate the voltage constraint at Tillsonburg TS substantially improves the thermal loading on this section line.

Reconfiguring the 115 kV system in the Aylmer-Tillsonburg Sub-Region and installing new switches at Buchanan TS to mitigate the voltage constraint at Tillsonburg TS also mitigates the thermal constraint on circuit W8T.

Installing capacitor banks at Tillsonburg TS reduces the loading on this section of W8T to 106% of its planning rating. As a result, upgrading this section of line would be required to increase the planning to rating to address the thermal overload based on the peak load forecast over the study period. Thirteen poles are required to be replaced at an estimated cost of $1.5 million. This will raise the planning rating of the line to match the other sections of circuit W8T.

A thermal constraint on a section of line approximately 1.5 km long on 115 kV circuit WT1T between Cranberry JCT and Tillsonburg TS was previously identified in the NA report. Tillsonburg Hydro has since provided a revised load forecast and there is no longer an overloading in this section of line.

7.2.3 Customer Delivery Point Performance

The Tillsonburg TS customer delivery point performance need was identified by the Working Group after the NA report was completed. Historical values indicated that the frequency of outages to Tillsonburg Hydro and Hydro One Distribution fall below the standards per Hydro One's "Customer Delivery Point Performance Standard" which is approved by the OEB.

The vast majority of interruptions to Tillsonburg Hydro and Hydro One Distribution at Tillsonburg TS results from having only one normal transmission supply to Tillsonburg TS. One method which substantially improves customer delivery point performance is to provide a second transmission circuit to supply Tillsonburg TS. In most situations, a second supply is normally cost prohibitive. Tillsonburg TS however is in a situation where there is an existing backup 115 kV circuit T11T within 3.5 km of the station. A second transmission supply to Tillsonburg TS would require extending 115kV circuit T11T from Cranberry JCT to Tillsonburg TS, HV bus work at Tillsonburg TS and protection relaying modifications and upgrades at Buchanan TS. Providing a second transmission supply to Tillsonburg TS is estimated to cost approximately $16 million.

7.2.4 Aylmer-Tillsonburg Sub-Region Recommended Plan

The Working Group examined various options to address the voltage, thermal and customer delivery point performance needs of the Sub-Region. The needs, options and alternatives are summarized in Tables 7-2, 7-3 and 7-4 respectively.

Table 7-2 Aylmer-Tillsonburg Sub-Region Needs

Need ID	Needs	Timing
I	Voltage constraint at Tillsonburg TS	Existing
II	Thermal constraint on W8T (Buchannan X Edgeware JCT)	Existing
III	Customer Delivery Point Performance below standards at Tillsonburg TS	Existing

Table 7-3 Aylmer-Tillsonburg Sub-Region Need Mitigation Options

#	Project	Lead Responsibility	I/S Date	Estimated Cost	Mitigated Need ID
1	Installation of Shunt Capacitors at Tillsonburg TS	HONI	2021	$8M	I
2	Installation of Switching at Buchanan TS and Reconfiguration of 115 kV Circuits	HONI	2019	$4M	I & II
3	W8T Circuit Upgrade	HONI	2021	$1.5M	II
4	Second transmission circuit supply to Tillsonburg TS	THI & HONI	2021	$16M	II & III

After further assessing the needs in Aylmer-Tillsonburg Sub-Region, the Working Group proposed a number of different options to mitigate the voltage, thermal and customer delivery point performance needs. Due to the complexity of the projects examined, it was determined that further assessment to clarify scope and specifically the cost details is needed. As such, the Working Group recommends Hydro One to pursue Budgetary Cost Estimates in order to obtain the necessary information to properly analyze the cost and benefits of each alternative.

Hydro One plans to obtain Budgetary Cost Estimates for the alternatives proposed and provide back the results to the Working Group by Q4 2018 in order to continue the planning activities for the Sub-Region.

Table 7-4 Aylmer-Tillsonburg Sub-Region Alternatives

Alternatives	Benefits/	Total Cost
I	Proceed with Projects I, III and IV -Resolves all three needs in the sub-region	$25.5M
II	Proceed with Project II -Resolves need I & II of the sub-region -Increase in the frequency interruptions at Tillsonburg TS -Lengthens restoration time (slightly) during forced outages -During planned or forced outages to W8T or T11T, switches at Buchanan, Lyon JCT and Cranberry JCT will be opened negating the voltage support effects	$4M
III	Proceed with Projects I and III -Resolves needs I & II in the sub-region	$9.5M

7.3 Long Term Regional Plan

As discussed in Section 5, the electricity demand in the London Area Region is expected to remain relatively constant over the study period (approximate growth rate of -0.3%). Load growth over the long term period is expected to be moderate (up to 1.5%) from 2027 to 2037. Long term forecast provides a high level insight of how the region may be developing in the future so that near and mid-term plans and ongoing projects in the region are best aligned with potential long term needs and solutions.

No long term needs for the London Area Region have been identified at this time. If new needs emerge due to a change in load forecast or any other reason, a new regional planning cycle will be initiated ahead of the 5-year planning cycle.

8. CONCLUSION AND NEXT STEPS

THIS RIP REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE LONDON AREA REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in Table 8-1.

Table 8-1 Regional Plans – Needs Identified in the Regional Planning Process

Need ID	Needs	Timing
I	Woodstock Sub-Region load restoration	Now
II	Greater London Sub-Region load restoration	Now
III	Voltage constraint at Tillsonburg TS	Now
IV	Thermal constraint on W8T	Now
V	Poor delivery point performance at Tillsonburg TS	Now
VI	EOL Asset – Wonderland TS transformer T5	2022

Projects, lead responsibility, and timeframes for implementing the wires solutions for the above needs are summarized in Table 8-2 below.

Table 8-2 Regional Plans – Projects, Lead Responsibility, and Planned In-Service Dates

#	Project	Lead Responsibility	I/S Date	Estimated Cost[9]	Mitigated Need ID
1	Distribution System Upgrades in the Greater London Sub-Region	London Hydro Inc.	2023	$1.8-4M ($180/kW)	II
2	Wonderland TS Reinvestment: Replace transformer T5	Hydro One Transmission	2022	$15-20M	VI

Woodstock Sub-Region load restoration need (Need ID I) was assessed by the Working Group during Local Planning and "status quo/do nothing" course of action has been recommended. Further developments in the Region will be monitored and the need will be reviewed again as part of the next planning cycle.

[9] Costs presented are preliminary estimate and may change resulting from clarification of scope and through detailed cost estimating.

Greater London Sub-Region load restoration need (Need ID II) was further assessed during Integrated Regional Resource Planning and the Working Group is recommending the implementation of automated switching devices and feeder extensions on the Distribution System as the most cost effective method to substantially mitigate the restoration shortfall in this area.

Due to the various needs of the Aylmer-Tillsonburg Sub-Region and the complexity of the options proposed, the Working Group is recommending Budgetary Cost Estimates be completed in order to obtain the necessary information to properly analyze the cost and benefits of each alternative.

In accordance with the Regional Planning process, the Regional Planning cycle will be triggered at least once within five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Peterborough to Kingston Region

Regional Infrastructure Plan ("RIP")

July 8th, 2016

Kingston Hydro
Hydro One Networks Inc. (Distribution)

The Peterborough to Kingston Region includes Frontenac County, Hasting County, Northumberland County, Peterborough County, and Prince Edward County.

The Needs Assessment ("NA") report for the Peterborough to Kingston region was completed in February, 2015 (see attached). The report concluded that there were only two needs in the region and that they should be addressed as follows:

a) Transformation capacity relief for Gardiner TS T1/T2 DESN1: to be addressed by a Local Plan ("LP").
b) Loading constraints on circuit Q6S: to be addressed by Bulk System Planning and not as part of Regional Planning.

An LP was undertaken by Hydro One Networks Inc. (Transmitter), Hydro One Networks Inc. (Distribution) and Kingston Hydro to address the transformation capacity relief for Gardiner TS T1/T2 DESN1 . The LP recommended re-distributing the load at Gardiner TS by transferring one feeder from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2. The estimated cost of this project is approximately $1.5M. An LP report was prepared and published by the Working Group for the Peterborough to Kingston region in October, 2015 (also attached).

There are no other major development projects planned for the Peterborough to Kingston Region over the near and mid-term

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no further regional coordination was required, the attached NA and LP reports will be deemed to form the ("RIP") for the Sudbury/Algoma Region.

The next planning cycle for the region will take place within five years of the start of this cycle (2014) or earlier, should there be a new need identified in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

Hydro One Networks Inc. (Distribution)	Ashley LeBel

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Peterborough to Kingston Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Peterborough to Kingston Region (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	December 12, 2014	**END DATE**	Feb 10, 2015

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the Peterborough to Kingston Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the Peterborough to Kingston Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Peterborough to Kingston Region belongs to Group 2. The NA for this Region was triggered on December 12, 2014 and was completed on Feb 10, 2015.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to the next 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2023.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning.

This NA included a study of transmission system connection facilities capability, which covers station and line loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One transmission provided information for the Peterborough to Kingston Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life. See Section 4 for further details.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs in the Region over the study period (2014 to 2023). The assessment reviewed available information and load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Capacity Needs

A. 230/115 kV Autotransformers

- The 230/115 kV autotransformers (Dobbin TS and Cataraqui TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

B. 230 kV Transmission Lines

- The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.
- Under high Transfer East of Cherrywood and low water conditions in the east, P15C may be loaded near its continuous rating under pre-contingency conditions. This issue will be further assessed by the IESO as part of bulk system planning.

C. 115kV Transmission Lines

- With the loss of 230 kV circuit P15C, the 115 kV circuit Q6S may reach its LTE ratings in the near term based on the gross load forecast. The net load in the area is forecasted to decrease from 2014-2023 with the inclusion of DG and CDM. No action is required at this time and the capacity need will be reviewed in the next planning cycle.
- The remaining 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.
- With the loss of 230 kV circuits P15C and C27P and expected load additional loading in Renfrew area in 2018, the circuit Q6S may be loaded beyond its LTE rating. This issue will be further assessed by the IESO as part of bulk system planning.

D. 230 kV and 115 kV Connection Facilities

- Gardiner TS T1/T2 DESN1 (summer peaking station) is forecasted to exceed its normal supply capacity from 2014 to 2023 based on the gross load forecast (approximately 112% and 117% of Summer 10-Day LTR in 2014 and 2023 respectively). However, based on the net load forecast with planned CDM targets and DG contributions, the station capacity for Gardiner TS T1/T2 DESN1 is adequate to meet the net forecasted load over the study period. It should be noted that Gardiner TS T3/T4 DESN2 is lightly loaded. Hydro One transmission will undertake an assessment of the need for load transfers as a local planning initiative and work with LDCs to develop a plan to balance load between the two DESNs

System Reliability, Operation and Restoration Review

Generally speaking, there are no significant system reliability and operating issues identified for this Region. Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

For the loss of two elements, the load interrupted by configuration may exceed 150 MW based on the gross coincident load forecast. However, based on the net coincident load forecast, the load interrupted by configuration does not exceed 150 MW. No action is required at this time.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace major equipment do not affect the needs identified.

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that

- "localized" wires only solutions be developed in the near-term to adequately and efficiently address the needs associated with transformation capacity relief for Gardiner TS T1/T2 DESN1 as indicated above through planning between Hydro One Networks Inc. and the impacted distributors. See Section 7 for further details, and
- IESO to assess loading constraints on circuit Q6S for the loss of two elements, and P15C under high transfers as part of their bulk system planning

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the Peterborough to Kingston Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the Peterborough to Kingston Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by the Peterborough to Kingston Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the IESO.

Table 1: Study Team Participants for Peterborough to Kingston Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
3.	Independent Electricity System Operator ("IESO")
4.	Kingston Hydro Corporation ("Kingston Hydro")
5.	Peterborough Distribution Inc. ("Peterborough Distribution")
6.	Veridian Connections Inc. ("Veridian")
7.	Hydro One Networks Inc. (Distribution)

2 REGIONAL ISSUE / TRIGGER

The NA for the Peterborough to Kingston Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Peterborough to Kingston Region belongs to Group 2. The NA for this Region was triggered on December 12, 2014 and was completed on Feb 10, 2015.

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the Peterborough to Kingston Region over an assessment period of 2014 to 2023. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station and line thermal capacity and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 Peterborough to Kingston Region Description and Connection Configuration

The Peterborough to Kingston Region includes Frontenac County, Hasting County, Northumberland County, Peterborough County, and Prince Edward County. The boundaries of the Peterborough to Kingston Region are shown below in Figure 1.

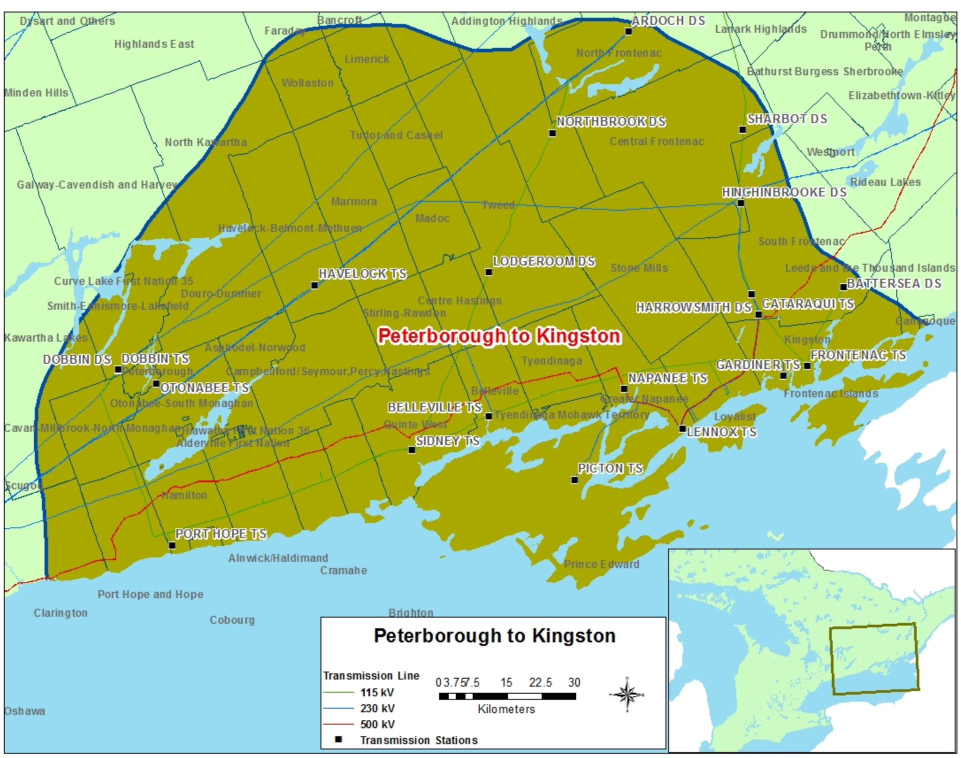

Figure 1: Peterborough to Kingston Region Map

Electrical supply to the Peterborough to Kingston Region is provided through a network of 230 kV and 115 kV circuits supplied by 500/230 kV autotransformers at Lennox Transformer Station (TS) and 230/115 kV autotransformers at Cataraqui TS and Dobbin TS. There are ten Hydro One step-down TS's, eight high voltage distribution stations (HVDS), and five other direct transmission connected load customers in the Region. The distribution system consists of voltage levels 44 kV, 27.6 kV, 12.5 kV, 8.32kV, and 4.16kV. The main generation facility in the Region is the 2000 MW Lennox Generation Station (GS) connected to Lennox TS.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 2. The 500kV system is part of the bulk power system and is not studied as part of this Needs Assessment:

- Lennox TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230 kV autotransformers.

- Cataraqui TS and Dobbin TS are the transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.

- Ten step-down transformer stations supply the Peterborough to Kingston load: Dobbin TS, Port Hope TS, Sidney TS, Picton TS, Otonabee TS, Havelock TS, Belleville TS, Napanee TS, Gardiner TS, and Frontenac TS. There are also eight HVDS that supply load in the Region: Dobbin DS, Ardoch DS, Northbrook DS, Lodgeroom DS, Hinchinbrooke DS, Harrowsmith DS, Sharbot DS, and Battersea DS.

- Five Customer Transformer Stations (CTS) are supplied in the Region: TransCanada Pipelines Cobourg CTS, TransCanada Pipelines Belleville CTS, Enbridge Pipelines Hilton CTS, Lafarge Canada Bath CTS, and Novelis CTS.

- There are 3 existing Transmission connected generating stations in the Region as follows:
  - Lennox GS is a 2000 MW natural gas-fired station connected to Lennox TS
  - NPIF Kingston GS is a 130 MW gas-fired cogeneration facility that connects to 230 kV circuits X1H and X2H near Lennox TS
  - Wolfe Island GS is a 198 MW wind farm connected to circuit X4H near Gardiner TS

- A 910 MW gas-fired plant (Napanee GS) is expected to connect to Lennox TS at the 500kV level in 2018.

- Up to 535 MW of additional transmission connected renewable generation could be in service in the Region by the year 2023.

- There are a network of 230 kV and 115 kV circuits that provide supply to the Region, as shown in Table 2 below:

Table 2: Transmission Lines in Peterborough to Kingston Region

Voltage	Circuit Designations	Location
230 kV	X1H, X2H, X3H, X4H	Hinchinbrooke SS to Lennox TS
	X21, X22	Picton TS to Lennox TS
	H23B	Belleville TS to Hinchinbrooke SS
	H27H	Hinchinbrooke SS to Havelock TS
	X1P	Dobbin TS to Chenaux TS
	C27P	Dobbin TS to Chat Falls GS
	H24C, H26C	Cherrywood TS to Havelock TS
	C28C	Cherrywood TS to Chat Falls GS
	P15C	Cherrywood TS to Dobbin TS
	B23C	Cherrywood TS to Belleville TS
115 kV	P3S, P4S	Dobbin TS to Sidney TS
	Q6S	Cataraqui TS to Sidney TS
	B1S	Barrett Chute TS to Sidney TS
	Q3K	Cataraqui TS to Frontenac TS
	B5QK	Cataraqui TS to Frontenac TS to Barrett Chute TS

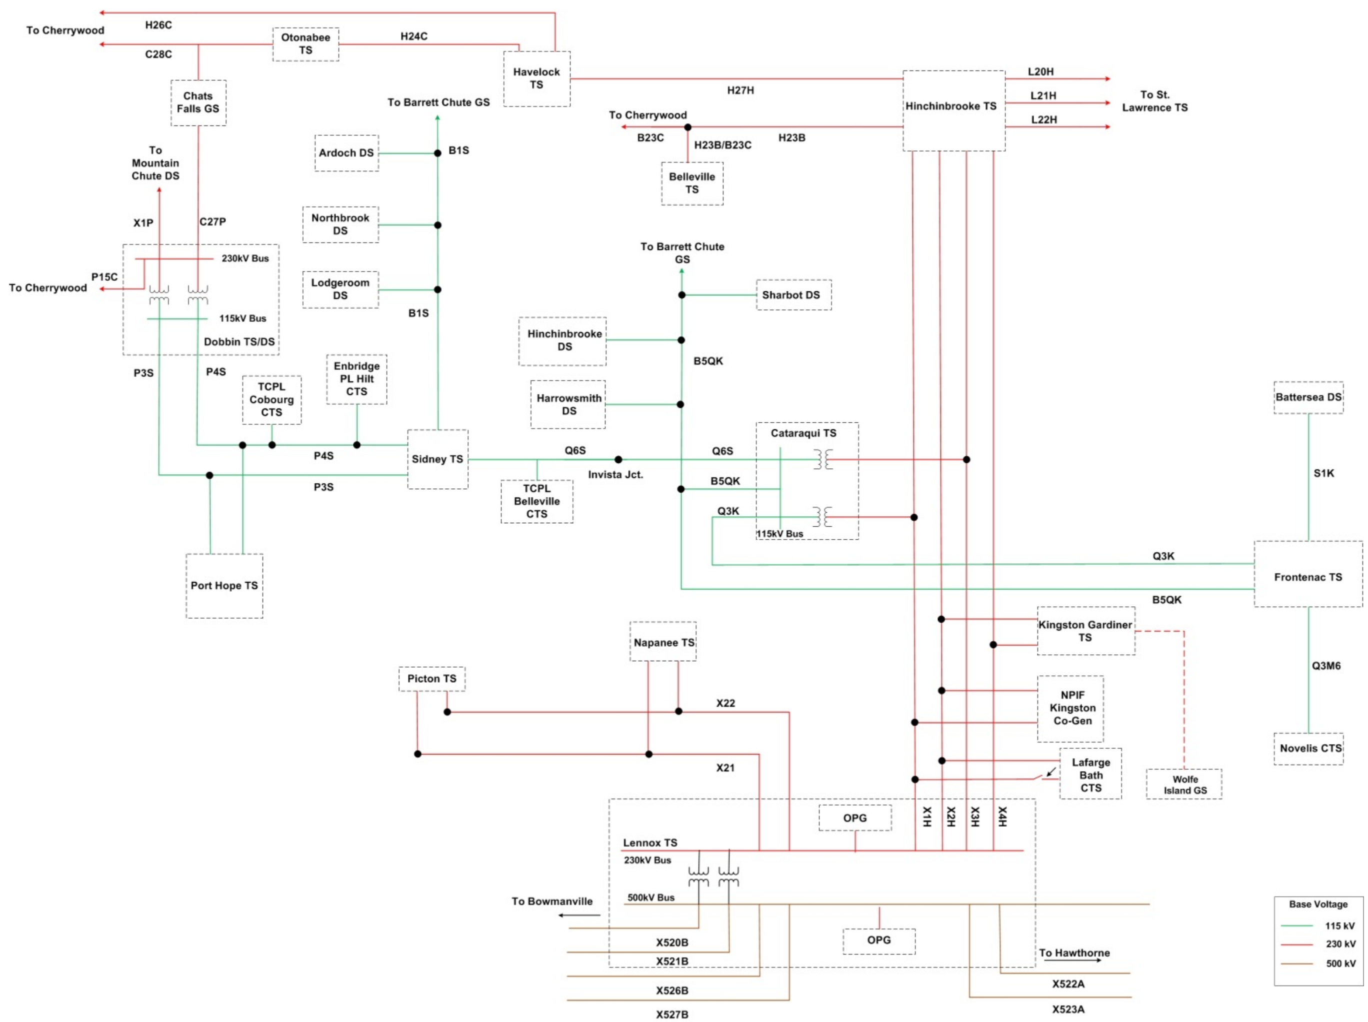

Figure 2: Single Line Diagram – Peterborough to Kingston Region

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
    i. Historical 2013 regional coincident peak load and station non-coincident peak load
    ii. List of existing reliability and operational issues
    iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2011-2013) net load, and gross load forecast (2014-2023)
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Gross Load Forecast

As per the data provided by the study team, the gross load in the Peterborough to Kingston Region is expected to grow at an average rate of approximately 0.4% annually from 2014-2023.

4.2 Net Load Forecast

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. The net load is expected to decrease at an average rate of approximately 0.6% annually from 2014-2023.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region consists of both winter and summer peaking stations. Therefore, this assessment is based on both winter and summer peak loads, as appropriate.

2. Forecast loads are provided by the Region's LDCs. LaFarge Canada had provided a load forecast for LaFarge Canada CTS. Load data was not received by the other industrial customers in the region (Enbridge Pipeline Inc, TransCanada Pipeline Ltd.). For these stations, the load was assumed to be consistent with historical loads.

3. The LDC's load forecast is translated into load growth rates and is applied onto the 2013 summer/winter peak load as a reference point.

4. The 2013 summer/winter peak loads are adjusted for extreme weather conditions according to Hydro One's methodology.

5. Accounting for (2), (3), (4) above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG is analyzed to determine if needs can be deferred.

   A coincident version of the gross and net load forecast was used to assess the transformer capacity needs (section 6.1.1), 230 kV transmission line needs (section 6.1.2), 115 kV transmission line needs (6.1.3) and system reliability operation and restoration needs (6.2).

   A non-coincident version of the gross and net load forecast was used to assess the station capacity as presented in section 6.1.4.

   A coincident peak load forecast and a non-coincident peak load forecast were produced for each gross load and net load forecasts.

6. Review impact of any on-going and/or planned development projects in the Region during the study period.

7. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.

8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer or winter 10-Day Limited Time Rating (LTR), as appropriate.

9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.

10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer or winter 10-Day LTR, as appropriate.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) (Section 4.2) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC (Section 7.2) criteria.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Peterborough to Kingston Region.

6.1 Transmission Capacity Needs

6.1.1 230/115 kV Autotransformers

The 230/115 kV autotransformers (Dobbin TS and Cataraqui TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.1.2 230 kV Transmission Lines

The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

Under high Transfer East of Cherrywood and low water conditions in Eastern Ontario, the 230 kV circuit P15C may be loaded near its continuous rating under pre-contingency conditions. This issue should be further assessed by the IESO as part of bulk system planning.

6.1.3 115kV Transmission Lines

With the loss of 230 kV circuit P15C, the 115 kV circuit Q6S from Invista Jct to Sidney TS may reach its LTE rating in the near term based on the gross load forecast. The net load forecast in the area is forecasted to decrease from 2014-2023 with the inclusion of DG and CDM. No action is required at this time and the capacity need will be reviewed in the next planning cycle.

With the loss of 230 kV circuits P15C and C27P and expected additional loading in the Renfrew region in 2018, the circuit Q6S may be loaded beyond its LTE rating. This issue should be further assessed by the IESO as part of bulk system planning.

The remaining 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.

6.1.4 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV TSs and HVDSs in the Region using either the summer or winter station peak load forecasts as appropriate that were provided by the study team. The results are as follows:

Gardiner TS

Gardiner TS T1/T2 DESN1 (summer peaking station) is forecasted to exceed its normal supply capacity from 2014 to 2023 based on the gross load forecast (approximately 112% and 117% of Summer 10-Day LTR in 2014 and 2023 respectively). However, based on the planned CDM targets and DG contributions, the station capacity for Gardiner TS T1/T2 DESN1 is adequate to meet the net forecasted demand over the study period.

It should be noted that Gardiner TS T3/T4 DESN2 is lightly loaded. Hydro One transmission will undertake an assessment of the need for load transfers as a local planning initiative and work with LDCs to develop a plan to balance load between the two DESNs

All the other TSs and HVDSs in the Region are forecasted to remain within their normal supply capacity during the study period. Therefore, no action is required at this time and the capacity needs will be reviewed in the next planning cycle.

6.2 System Reliability, Operation and Restoration Review

Generally speaking, there are no significant system reliability and operating issues identified for this Region.

Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

For the loss of circuits X2H and X4H, the load interrupted by configuration at Gardiner TS may exceed 150 MW based on the gross coincident load forecast. However, based on the net coincident load forecast, which accounts for CDM and DG, the load interrupted by configuration does not exceed 150 MW. Therefore, no action is required at this time and this will be reviewed in the next planning cycle.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables.

During the study period:

- Replacement (like-for-like) of both transformers (T1 and T2) at Gardiner TS DESN1 is scheduled in 2020. The replacement plan does not affect the results of this NA study.

- Replacement of two autotransformers, T2 and T5 (78 MVA and 115 MVA respectively), at Dobbin TS with a single 150/250 MVA autotransformer is scheduled in 2019. The third autotransformer (T1) will remain the same. The replacement plan does not affect the results of this NA study.

- There are no significant lines sustainment plans that will affect the results of this NA study.

7 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, the study team recommends that no further coordinated regional planning is required.

Rather the study team recommends the following to address the identified needs:

a) Hydro One transmission will lead the assessment and develop a local plan ("Gardiner TS Load Balancing") with the relevant LDCs to balance load between the two DESNs at Gardiner TS; and,
b) IESO to assess and develop a plan for the contingencies associated with circuit Q6S for the loss of two elements and loading constraints on circuit P15C under high transfers within the context of a bulk planning study for the area.

8 NEXT STEPS

Hydro One Transmission and impacted LDCs will address the recommendation in Section 7a and develop a local plan.

IESO to initiate a bulk planning study for the area.

GARDINER TS LOAD BALANCING

Region: Peterborough to Kingston

Revision: FINAL
Date: October 7, 2015

Prepared by: "Peterborough to Kingston" Region Local Planning Study Team

Peterborough to Kingston Region Local Planning Study Team
Organization
Hydro One Networks Inc. (Lead Transmitter)
Hydro One Networks Inc. (Distribution)
Kingston Hydro (Embedded LDC)

DISCLAIMER

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the Peterborough to Kingston Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	Peterborough to Kingston (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	April 10, 2015	**END DATE**	October 7, 2015

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the Peterborough to Kingston Region. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

2. LOCAL NEED ADDRESSED IN THIS REPORT

The Needs Assessment (NA) report for the Peterborough to Kingston Region indicated that Gardiner TS T1/T2 DESN1 is forecasted to exceed its normal supply capacity in the near term. Gardiner TS T3/T4 DESN2 is lightly loaded. The local need addressed in this report will be how to best alleviate the station capacity issue at Gardiner TS T1/T2 DESN1.

3. ALTERNATIVES CONSIDERED

The alternatives considered were:

1) Transfer load from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN
2) Do Nothing

4. PREFERRED ALTERNATIVE

Transferring load from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2 is the preferred alternative as it addresses the station capacity issue at Gardiner TS T1/T2 DESN1. Transferring some of the existing load at Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2 is the most straight forward and cost effective option.

5. RECOMMENDATIONS

Hydro One Distribution will proceed with a detailed estimate for the load transfer work at Gardiner TS. The detailed estimate for the load transfer work is expected to be completed mid-2016. The expected in-service date for this work is end of 2018.

Table of Contents

1 Introduction

The Needs Assessment (NA) for the Peterborough to Kingston Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 Regions is complete and will be initiated for Group 3 Regions later this year. The Peterborough to Kingston Region belongs to Group 2. The NA for this Region was triggered on December 12, 2014 and was completed on Feb 10, 2015. The NA for the Peterborough to Kingston Region was prepared jointly by the study team, including Local Distribution Companies (LDC), Independent Electric System Operator (IESO), Ontario Power Authority (merged with IESO as of January 2015 and herein referred to as IESO), and Hydro One. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the Peterborough to Kingston Region over the next ten years (2014 to 2023) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

This report was prepared by the Peterborough to Kingston Region LP study team (Table 1) and led by the transmitter, Hydro One Networks Inc. (Hydro One). The report captures the results of the assessment based on information provided by LDCs and Hydro One.

2 Regional Description

The Peterborough to Kingston Region includes Frontenac County, Hasting County, Northumberland County, Peterborough County, and Prince Edward County. Please refer to the NA Report for further details. The Peterborough to Kingston Region and its approximate boundaries are shown in Figure 1. The facilities in the Region are depicted in the single line diagram shown in Figure 2.

5

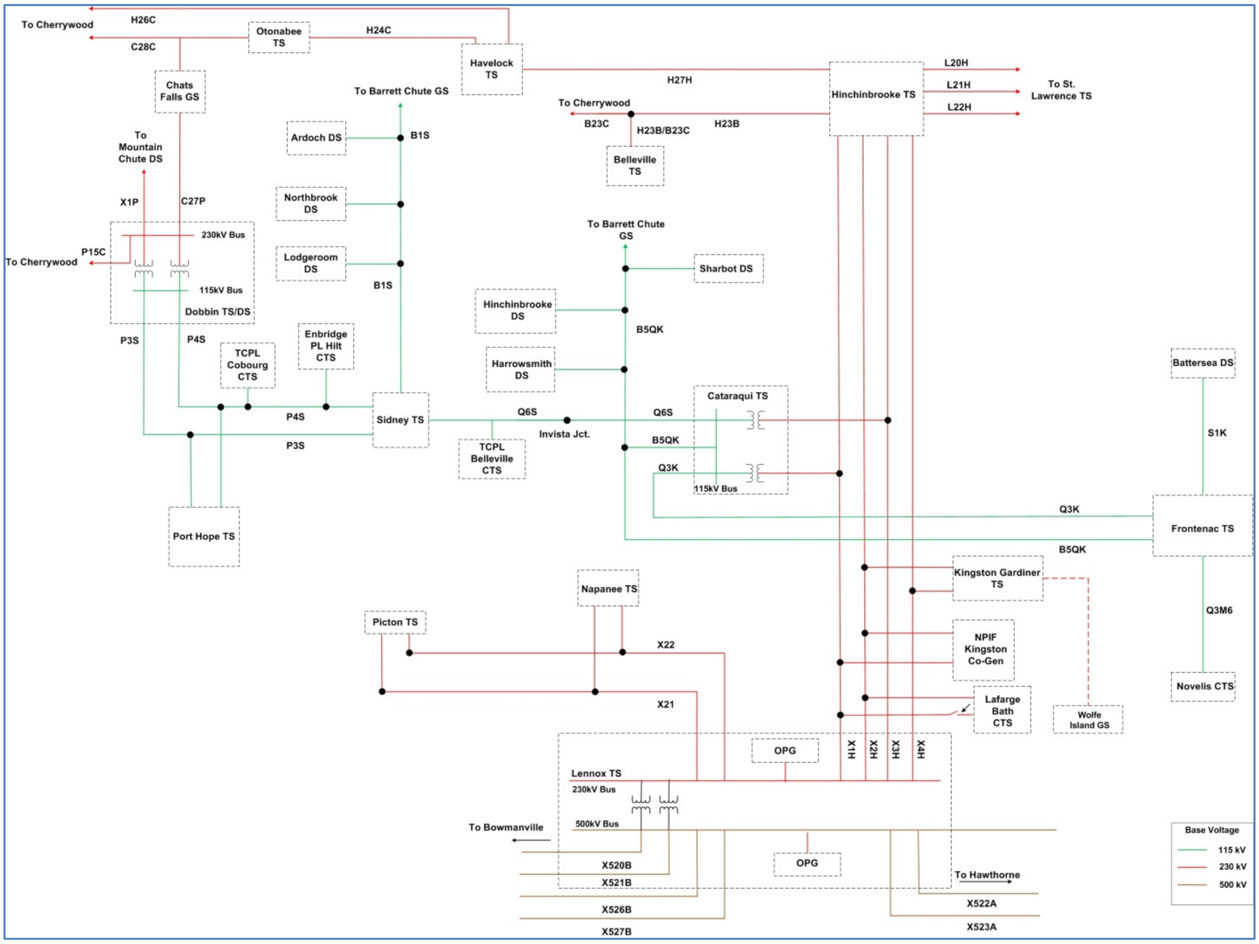

Figure 2: **Single Line Diagram – Peterborough to Kingston Region**

6

3 Peterborough to Kingston Region Needs

As an outcome of the NA process, the study team identified a need to address the normal supply capacity at Gardiner TS T1/T2 DESN1. Since this need can be clearly addressed by a straightforward wires solution, the study team agreed that it should be further planned directly by the impacted LDC and the transmitter through the LP process and that further coordinated regional planning was not required. Hydro One with the impacted LDCs further undertook planning assessments to develop options and recommend a wires only solution(s). Gardiner TS (230/44 kV)

3.1 Gardiner TS (230/44kV)

Gardiner TS T1/T2 DESN1 is forecasted to exceed its normal supply capacity from 2014 to 2023 based on the gross load forecast (approximately 112% and 117% of Summer 10-Day LTR in 2014 and 2023 respectively). However, based on the net load forecast which takes planned CDM targets and DG contributions into consideration, this issue will be avoided. Nevertheless, the station will still be loaded at 100% of its thermal capacity at that time. The load forecast provided by LDCs and the CDM and DG forecast provided by the IESO are attached in Appendix A.

4 Options Considered

This section describes the options considered to address the local need described in section 3.1.

4.1 Gardiner TS Load Balancing

Prior to the regional planning process, Hydro One Distribution had already planned on re-distributing the load at Gardiner TS by transferring one feeder from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2. This would alleviate the loading concerns at Gardiner TS T1/T2 DESN1 for this study period. The preliminary budgetary cost estimate for this project is about $1.5M.

4.2 Do Nothing

Do nothing is not a viable option since it could result in the violation of transformer ratings at Gardiner TS T1/T2 DESN1, which is not acceptable.

5 Recommendation

The study team agreed that transferring one feeder from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2 would relieve the thermal loading at Gardiner TS T1/T2 DESN1. This is a cost effective solution that will ensure that any additional load growth during the study period at Gardiner TS can be accommodated without exceeding the station thermal limit. Hydro One Distribution will be proceeding with the development of a plan to transfer the load along with a cost estimate for the work by the end of 2015. The expected in-service date for this feeder load transfer is end of 2018.

REGIONAL INFRASTRUCTURE PLAN

August 18th, 2017

hydro one

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Independent Electricity System Operator
Alectra Utilities Corporation (formerly PowerStream Inc.)
Hydro One Networks Inc. (Distribution)
InnPower Corporation
Orangeville Hydro Ltd.
Veridian Connections Inc.

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Study Team.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Study Team.

Study Team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE NETWORKS INC. ("HYDRO ONE") AND THE STUDY TEAM IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS OF THE SOUTH GEORGIAN BAY/MUSKOKA REGION.

The participants of the RIP Study Team included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator
- Alectra Utilities (formerly PowerStream Inc.)
- Hydro One Networks Inc. (Distribution)
- InnPower Corporation
- Orangeville Hydro Ltd.
- Veridian Connections Inc.

This RIP is the final phase of the OEB's mandated regional planning process for the South Georgian Bay/Muskoka Region. It follows the completion of Integrated Regional Resource Plans ("IRRP") for Barrie/Innisfil and Parry Sound/Muskoka Sub-Regions on December 16, 2016.

This RIP provides a consolidated summary of the needs and recommended plans for the South Georgian Bay/Muskoka Region which includes the Barrie/Innisfil and Muskoka/Parry Sound Sub-Regions. The major transmission and distribution infrastructure investments planned for the South Georgian Bay/Muskoka Region over the near and mid-term, as identified in the various phases of the regional planning process are given in the Table below.

No.	Project	I/S Date	Cost ($ Million)
1	Replacement of 115-44kV transformers (T1 and T2) at Barrie TS, uprating 115kV circuits to 230kV, adding additional feeders to Barrie DESN	2020/2021	$84
2	Replacement of 230-44kV transformers (T1 and T2) and possible rebuild of low voltage switchyard at Minden TS	2020/2021	$17
3	Installation of sectionalizing motorized disconnect switches on circuits M6E/M7E (at Orillia TS)	2021	$5-7
4	Build new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS*	2020	$7
5	Replacement of 230/44 kV transformers at Parry Sound TS*	2021	$20
6	Replacement of dual windings 230-44/27.6kV transformers (T1 and T2) and associated low voltage equipment at Orangeville TS	2024/2025	$33

* Replacement of transformers at Parry Sound TS would eliminate the need to build new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS

A load transfer from Barrie TS to Midhurst TS that is planned for 2019 will address the near-term capacity need at Barrie TS and will defer the capacity need of the upgraded Barrie TS to 2031.

A cost-benefit/responsibility analysis will be considered by Hydro One Distribution, Lakeland Power and Veridian Connections to improve reliability performance of the Parry Sound/Muskoka 44 kV sub-transmission system, which will be completed by the end of 2017.

As per the Regional Planning process, the Regional Plan will be reviewed and/or updated at least once every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle can also be started earlier.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE SOUTH GEORGIAN BAY/MUSKOKA REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the study with input and consultation with Hydro One Distribution, Alectra Utilities (formerly PowerStream Inc.) ("Alectra"), Veridian Connections Inc. ("Veridian"), Innisfil Hydro Distribution Systems Ltd ("InnPower"), Orangeville Hydro Ltd ("Orangeville Hydro") and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The South Georgian Bay/Muskoka region consists of the area roughly bordered by the Municipality of West Nipissing to the northwest, Algonquin Provincial Park to the northeast, Peterborough County and Hastings County to the southeast, Lake Scugog, York and Peel Regions to the south, Wellington County to the southwest and the Municipality of Grey Highlands to the west. Figure 1-1, on the following page, shows the boundaries of the South Georgian Bay/Muskoka Region.

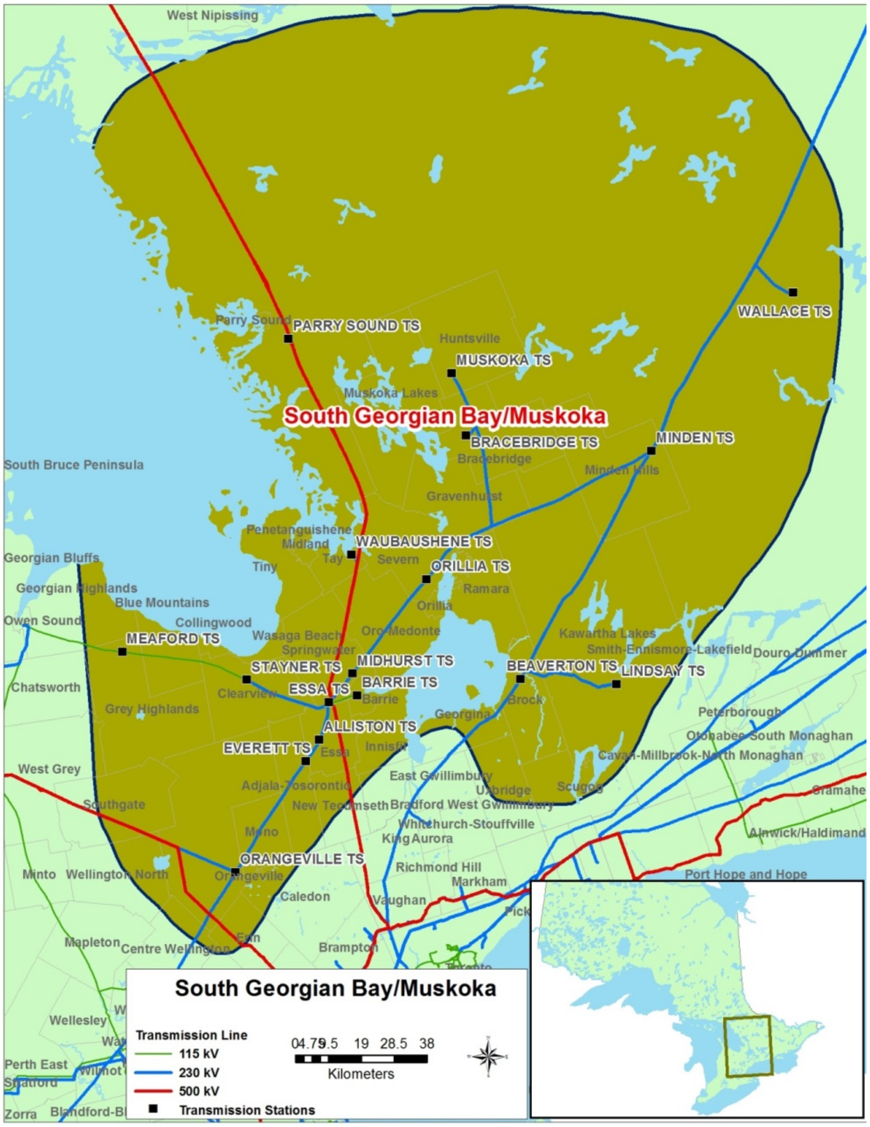

Figure 1-1 South Georgian Bay/Muskoka Region

1.1 Scope and Objectives

This RIP report examines the needs in the South Georgian Bay/Muskoka Region. Its objectives are to:

- Identify new needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plan to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and/or distribution facilities that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the Region's load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2016-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2016-2025 period and a wires plan to address them;
- Consideration of long-term needs identified in the Barrie-Innisfil and Parry Sound/Muskoka sub-region IRRPs.

As per the Regional Planning process, the Regional Plan for the region will be reviewed and/or updated at least every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle can also be started earlier.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the regional characteristics
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the regional needs
- Section 7 describes the needs and provides the alternatives and preferred solutions
- Section 8 provides the conclusion and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is performed at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115kV and 230kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Study Team determines whether further regional coordination is necessary to address them. If no further regional coordination or comprehensive planning is required an assessment is undertaken for any necessary investments directly by the LDCs (or customers) and the transmitter through a Local Plan ("LP"). These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. If there are needs that do not require regional coordination, the Study Team can recommend them to be undertaken as part of the LP approach discussed above. Otherwise, the approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region is identified in the NA phase, it is possible that different approaches could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP

[1] Also referred to as Needs Screening.

phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee ("LAC") in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timeline provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project-specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

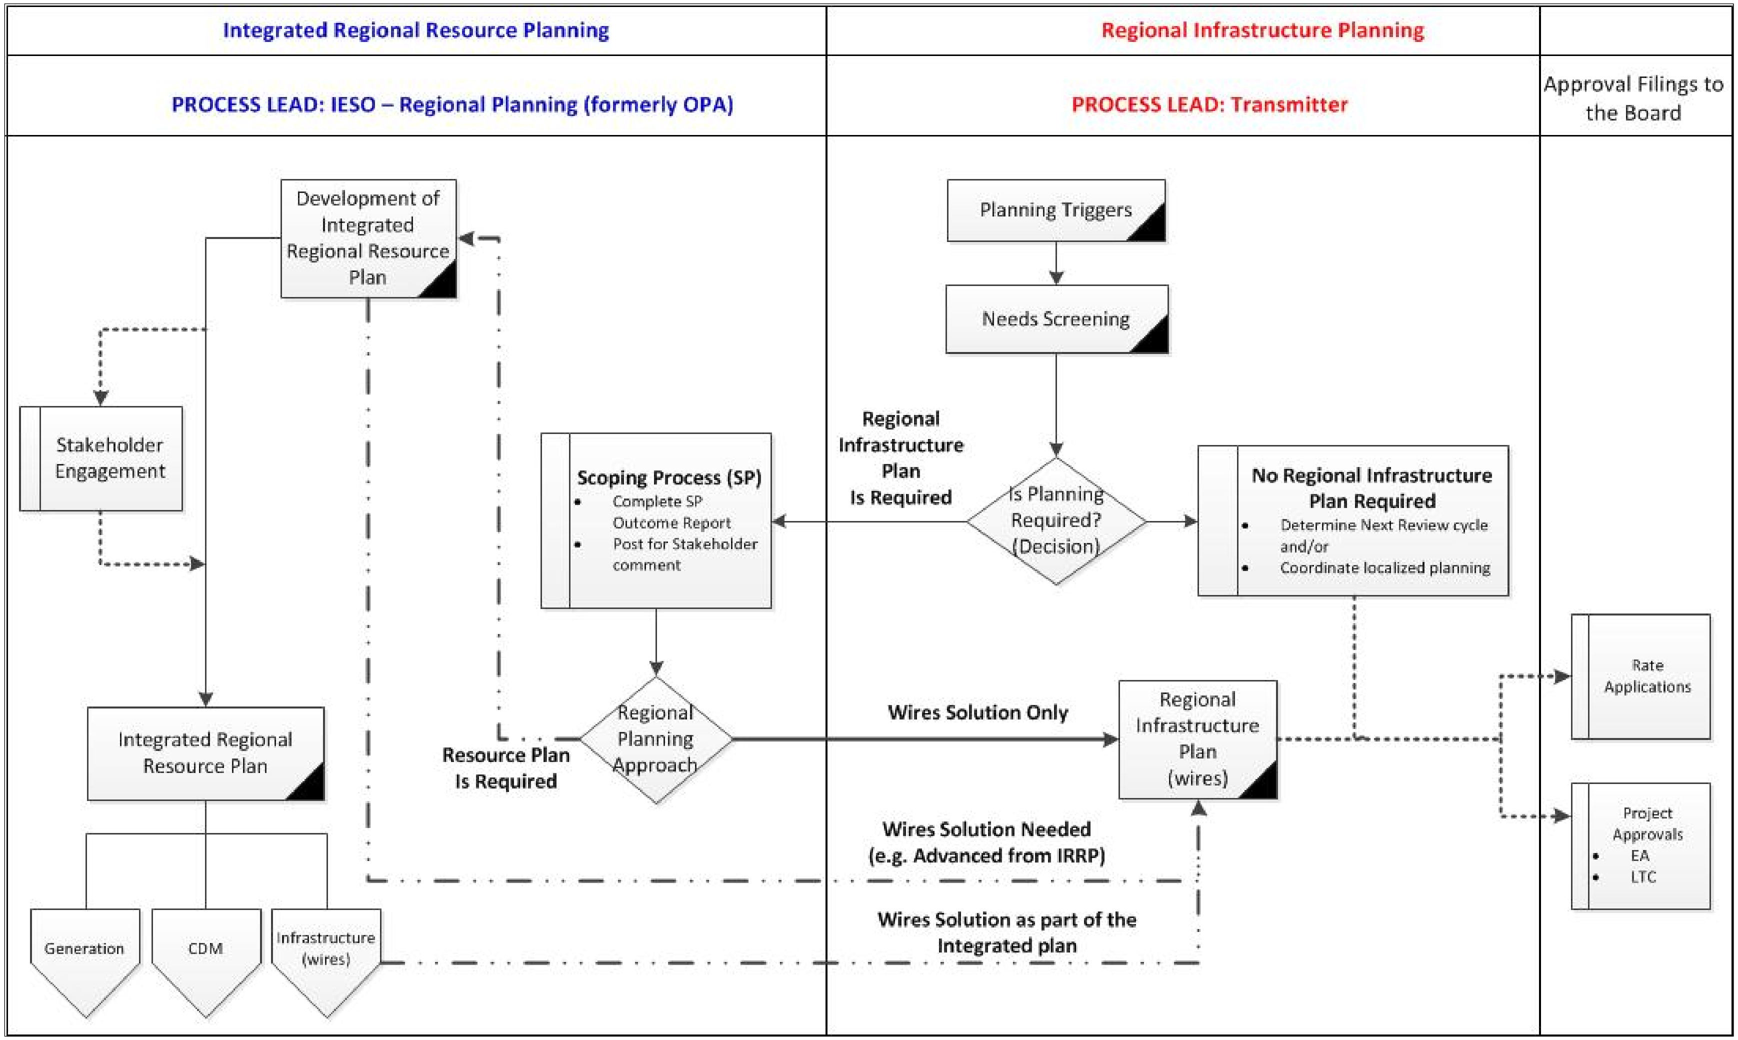

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. **Data Gathering:** The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects the following information and reviews it with the Study Team to reconfirm or update the information as required:
    - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation ("DG") or CDM programs;
    - Existing area network and capabilities including any bulk system power flow assumptions;
    - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.
2. **Technical Assessment:** The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. **Alternative Development:** The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.
4. **Implementation Plan:** The fourth and last step is the development of the implementation plan for the preferred alternative.

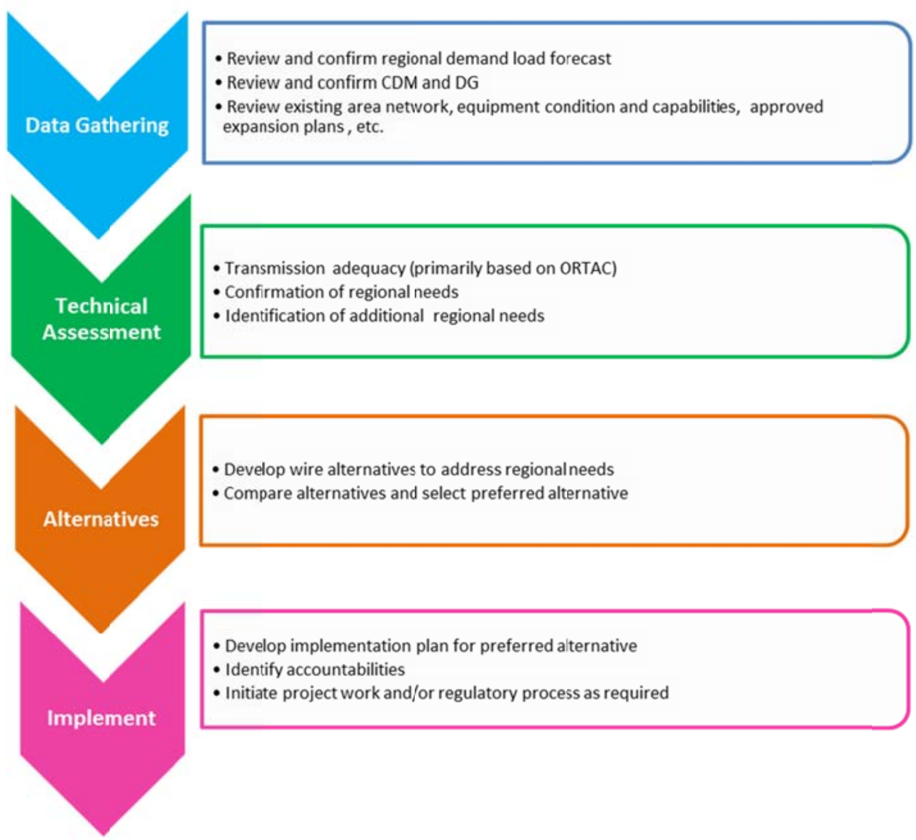

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE SOUTH GEORGIAN BAY/MUSKOKA REGION IS COMPRISED OF THE BARRIE/INNISFIL AND THE PARRY SOUND/MUSKOKA SUB-REGIONS. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM TWO AUTO-TRANSFORMERS AT ESSA TS, THE 230KV TRANSMISSION LINES D1M, D2M, D3M AND D4M CONNECTING MINDEN TS TO DES JOACHIMS TS, THE 230KV CIRCUITS E8V AND E9V COMING FROM ORANGEVILLE TS AND THE SINGLE 115KV CIRCUIT S2S CONNECTING TO OWEN SOUND TS. THE 2015 WINTER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 1,350 MW INCLUDING DIRECT TRANSMISSION-CONNECTED CUSTOMERS.

There are sixteen Hydro One-owned step-down transformer stations in the Region, most of which are supplied by circuits radiating out from Essa TS, and the majority of the distribution system is at 44kV, except for Orangeville TS which has 27.6kV and 44kV feeders.

The March 2013 South Georgian Bay/Muskoka Region NA report, prepared by Hydro One, considered the South Georgian Bay/Muskoka as a whole. Subsequently as a result of the Scoping Assessment, the South Georgian Bay/Muskoka Region was divided into two sub-regions, Barrie/Innisfil Sub-Region and Parry Sound-Muskoka Sub-Region. An IRRP was undertaken for each sub-region. A map of the South Georgian Bay/Muskoka Region is shown in Figure 3-1 and a single line diagram of the transmission system is shown in Figure 3-2.

3.1 Barrie/Innisfil Sub-Region

The Barrie/Innisfil Sub-Region roughly encompasses the City of Barrie and the towns of Innisfil, New Tecumseth and Bradford West Gwillimbury. It includes the townships of Essa, Springwater, Clearview and Mulmur, Adjala-Tosorontio. The Barrie/Innisfil Sub-Region includes the areas supplied by Midhurst TS, Barrie TS, Everett TS, and Alliston TS, and transmission circuits E8V/E9V, E3B/E4B, and M6E/M7E.

3.2 Parry Sound/Muskoka Sub-Region

This sub-region roughly encompasses the Districts of Muskoka and Parry Sound and the northern part of Simcoe County. The Parry Sound/Muskoka Sub-Region includes the areas supplied by Parry Sound TS, Waubaushene TS, Orillia TS, Bracebridge TS, Muskoka TS, and Minden TS, and transmission circuits M6E/M7E and E26/E27.

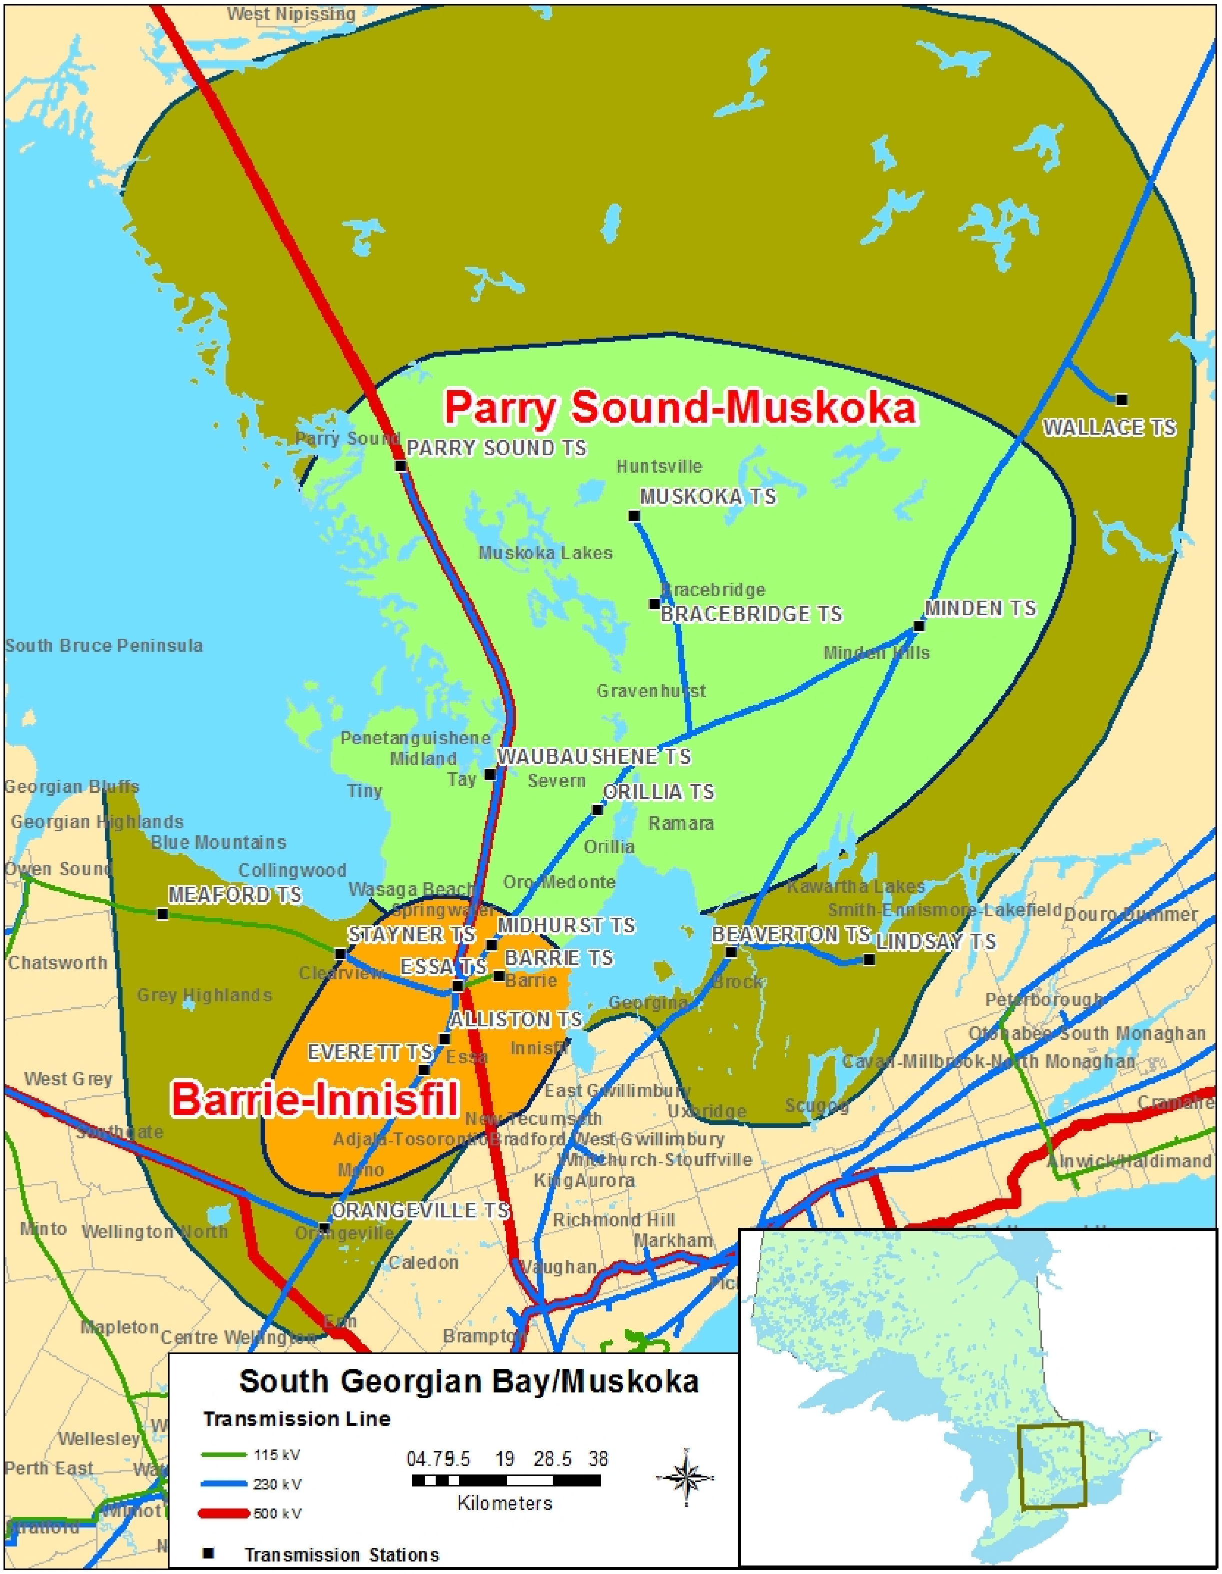

Figure 3-1 South Georgian Bay/Muskoka – Supply Areas

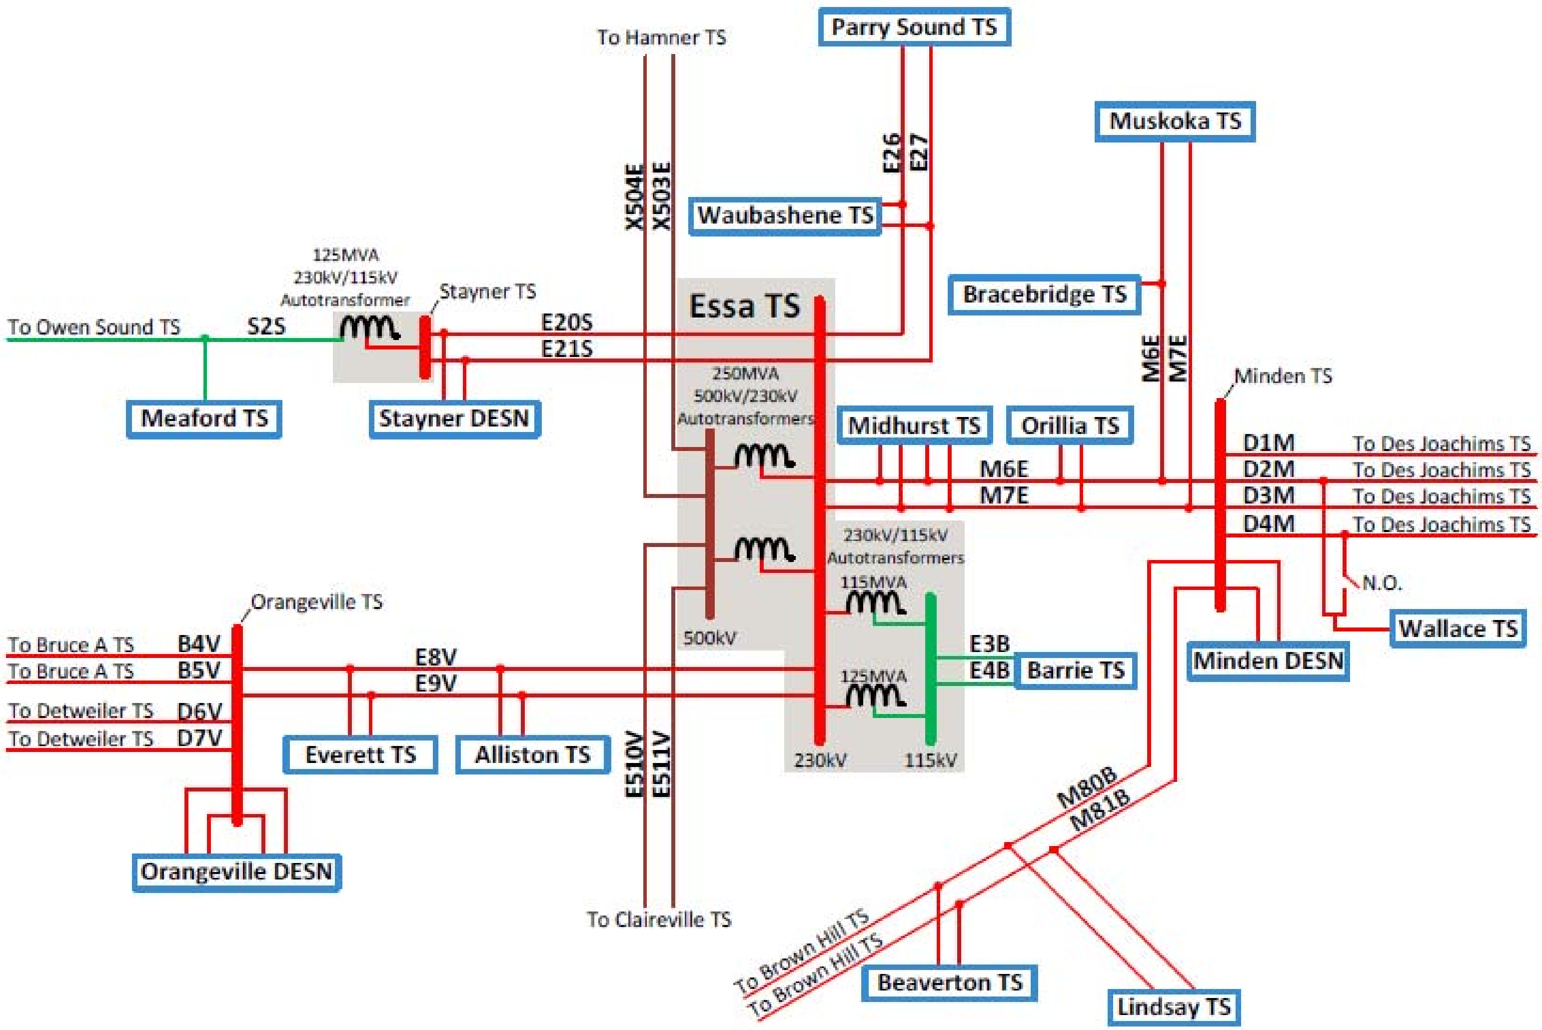

Figure 3-2 South Georgian Bay/Muskoka Region Single Line Diagram (Current)

4. TRANSMISSION FACILITIES COMPLETED OR CURRENTLY UNDERWAY OVER LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR HAVE BEEN INITIATED, AIMED AT IMPROVING THE SUPPLY TO THE SOUTH GEORGIAN BAY/MUSKOKA REGION.

A brief listing of the development projects along with their in-service dates over the last 10 years is given below:

- Everett TS (2007) – Construction of new 50/85 MVA 230/44 kV Everett transformer station to alleviate load from Alliston TS, which was loaded beyond its capacity, and provide additional capacity for the load growth in the South Georgian Bay area.

- South Georgian Bay Transmission Reinforcement (2009) – Replacement of 27 km of 115 kV single circuit (S2E) between Essa TS and Stayner TS with a 230 kV double circuit (E20S/E21S) to improve supply reliability and prevent excessive post-contingency voltage decline. Replacement of two 50/83 MVA 115/44 kV step-down transformers at Stayner TS with two 75/125 MVA 230/44 kV transformers to provide additional capacity for the load growth in the South Georgian Bay area.

- Essa TS Shunt Capacitor Bank (2010) – Installation of one (1) 230 kV 245 MVAr shunt capacitor bank to address the need for added voltage support to increase the transfer capability of power from north to south and accommodate committed generation facilities north and west of Sudbury.

- Midhurst TS and Orillia TS Capacitor Banks (2012) – Installation of four (4) 44 kV 32.4 MVAr capacitor banks at Midhurst TS and Orillia TS (2 banks at each station) to minimize post-contingency voltage decline on the low voltage buses at both stations and improve the power quality for customers.

- Meaford TS Transformer Replacement (2015) – Like-for-like replacement of 25/42 MVA 115/44 kV transformers that were over 60 years old and nearing end-of-life.

The following development projects are expected to be placed in-service within the next 5-10 years:

- Barrie TS (2020/2021) – Hydro One is working with IESO, Alectra Utilities, InnPower, and Hydro One Distribution to replace the aging infrastructure while also addressing the growth related needs. The plan entails uprating 115kV lines E3B/E4B to 230kV, upgrading existing DESN transformer from 115/44 kV, 55/92 MVA to 230/44 kV, 75/125 MVA, increasing the number of feeders at Barrie TS, and removing the two 230/115 KV auto-transformers and 115 kV switchyard at Essa TS.

- Minden TS (2020-2021) – A recent station assessment has identified that power transformers T1 and T2, protection and control equipment, and select 44kV switchyard assets are degrading in condition and require replacement. Work involves replacing existing T1 & T2 three-phase power transformers with standard size three-phase power transformers, and upgrading and replacing the 44kV switchyard components.

- Orangeville (2024-2025) End-of-life transformers T1 and T2 (non-standard) will be replaced with two standard three-phase transformers sized 215.5-28 kV, 50/66.7/83.3 MVA units and T3 and T4 will be replaced with standard 215.5-44 kV, 75/100/125 MVA units. To standardize the configuration, the T1/T2 switchyard will be reconfigured as a single 230-28 kV switchyard and the two existing 44 kV feeders, M45 and M46, will be relocated and supplied from the T3/T4 DESN. Associated end-of-life protection, control and telecom assets and station service equipment is also planned for replacement.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the South Georgian Bay/Muskoka Region is expected to increase at an annual rate of approximately 1.17 % between 2016 and 2034. The growth rate varies across the Region but an overall coincident growth in the Region is illustrated in Figure 5-1. The winter and summer, gross and net non-coincident load forecast, adjusted for extreme weather, CDM, and DG, for each station in the region are provided in Appendix C and D.

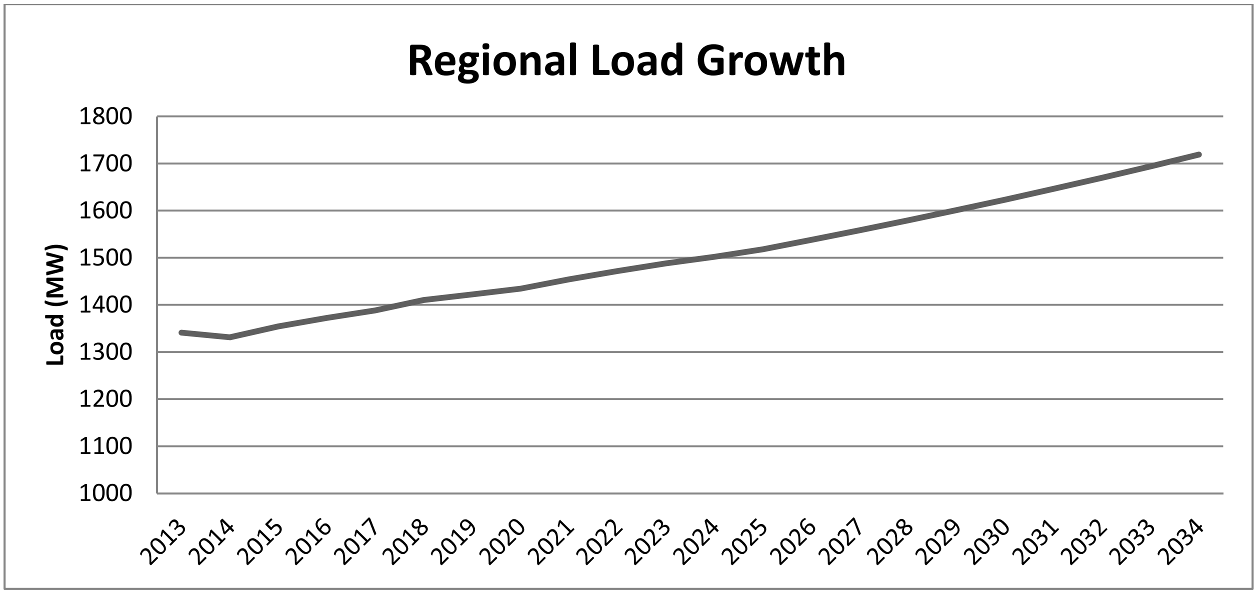

Figure 5-1 South Georgian Bay/Muskoka Region Winter Coincident Net Load Forecast

Prior to the RIP's kick-off, the Study Team was asked to confirm the load forecast for all stations in the Region provided for previous assessments. The RIP's load forecast for South Georgian Bay/Muskoka Region did not have a significant revision compared to the IRRP's load forecast.

5.2 Other Study Assumptions

Further assumptions are as follows:

- The study period for the RIP assessment is 2014 – 2034.
- The Region is winter peaking, however five out of sixteen stations in the Region are summer peaking (Alliston TS, Barrie TS, Everett TS, Midhurst TS and Orangeville TS T1/T2 DESN). Therefore, this assessment is based on both winter and summer peak loads, as appropriate.
- "Barrie Area Transmission Upgrade project" to be completed by the end of 2020.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-

voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.[2] Normal planning supply capacity for transformer stations in this region is determined by the summer 10-Day Limited Time Rating ("LTR") or the winter 10-Day LTR depending on what season the station peaks.

- Barrie TS is forecasted to experience the highest average yearly growth rate of any TS in the study area over the 20 year planning period for all growth scenarios.

[2] These power factor assumptions differ from those in the IRRP, which assumes a 90% lagging power factor for all stations. This results in differences in need dates for station capacity when comparing the IRRP and the RIP.

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND STEP DOWN TRANSFORMATION STATION FACILITIES SUPPLYING THE SOUTH GEORGIAN BAY/MUSKOKA REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM PERIOD.

Within the current regional planning cycle, six regional assessments have been conducted for the South Georgian Bay/Muskoka Region. The findings of these studies are an input to the RIP:

1. South Georgian Bay/Muskoka Region Needs Assessment Report – March 3, 2015 [2]
2. South Georgian Bay/Muskoka Region Scoping Assessment Report – June 22, 2015 [3]
3. Local Planning Report – Orangeville TS End of life ("EOL") Replacement – May 27, 2016 [4]
4. Barrie/Innisfil Sub-Region IRRP – Dec. 16, 2016 [5]
5. Parry Sound/Muskoka Sub-Region IRRP – Dec. 16, 2016 [6]

The NA, IRRP, and LP studies identified a number of regional needs based on the forecast load demand over the near to mid-term. A detailed description and status of plans to meet these needs is given in Section 7.

Based on the regional growth rate referred to in Section 5, this RIP reviewed the loading on transmission lines and stations in the South Georgian Bay/Muskoka Region assuming Essa/Barrie and E3B/E4B upgrade to be completed by 2020/2021, Minden DESN transformer replacement and 44kV upgrade to be completed by November 2020/2021, and Orangeville transformer replacement and station reconfiguration to be completed by October 2024/2025.

Sections 6.1-6.3 present the results of this review and Table 6-1 lists the Region's near, mid and long-term needs identified in both the IRRP and RIP phases.

Table 6-1 Near, Mid and Long-Term Needs in the South Georgian Bay/Muskoka Region

Type	Section	Needs	Timing
Station Capacity	7.1	Barrie TS (existing 115/44kV configuration)	Today
	7.2	Barrie TS (future 230/44kV configuration)	2031[3]
	7.7	Everett TS	2027
	7.3	Parry Sound TS	Today
	7.7	Waubaushene TS	2027[4]
Transmission line capacity	7.1	E3B/E4B forecasted to exceed their Load Meeting Capability (LMC)	2019
Load Restoration	7.4	Load Restoration for loss of double-circuit M6E/M7E	Today
Load Security	7.7	Load Security for M6E/M7E – load growth may exceed its 600 MW LMC	Early 2030s
Outage Duration and Frequency	7.5	44kV Parry Sound/Muskoka Sub-Region experience below average performance w.r.t frequency and duration of outages	Today
Distribution Feeder Capacity	7.6	The one Barrie TS feeder that is designated to InnPower will exceed its normal operating rating	2020
End of Life	7.8	Minden TS (two transformers and associated ancillary equipment)	2020/2021
	7.9	Orangeville TS (All four transformers)	2024/2025
	7.3	Parry Sound TS (one transformer, T2)[5]	2021

6.1 115kV and 230kV Transmission Facilities

The South Georgian Bay/Muskoka Region is comprised of mostly 230kV circuits, M6E/M7E, E8V/E9V E26/E27, E20S/E21S, D1M/D2M/D3M/D4M, M80B/M81B, and one pair of 115kV circuits E3B/E34B, supplying the Barrie/Innisfil and Parry Sound/Muskoka Sub-Regions and other areas outside the two sub-regions. Refer to Figure 3-2 for existing facilities in the Region.

[3] The LTR for the upgraded Barrie TS has been updated since the 2016 Barrie/Innisfil IRRP due to change in the planning LTR factor and changes in power factor assumptions. An increase of approximately 10.75 MW for the summer 10-day LTR (2.25 MW from the LTR factor change and 8.5 MW from the differing power factor assumptions) resulted in a deferral of the need date from 2026 (as indicated in the IRRP) to 2031 in the RIP report. As well, the IRRP forecast included an extreme weather correction which also contributes to the difference in need date.

[4] The LTR for Waubaushene TS has been updated since the 2016 PSM IRRP due to changes in power factor assumptions. For the 2016 PSM IRRP, it was assumed that all transformer stations have a 90% power factor. For the SGBM RIP, it was assumed that stations without low voltage capacitor banks have a 90% power factor and stations with low-voltage capacitor banks have a 95% power factor. Since Waubaushene TS has low voltage capacitor banks, the power factor was changed from 90% to 95% in the SGBM RIP, resulting in a higher LTR and a later need date as compared to the findings in the 2016 PSM IRRP.

[5] Parry Sound TS was placed in service in 1970 and has been supplying power to parts of the Region for almost 50 years. Field crews have recently observed that one of the two power transformers is in poor operating condition.

Bulk system planning is being conducted by the IESO and is also informed by government policy such as the Long-Term Energy Plan (LTEP). The next LTEP is expected to be issued in 2017. Any outcomes impacting planning decisions will be later updated in this regional planning report.

6.2 Barrie/Innisfil Sub-Region's Step-Down Transformer Station Facilities

There are four step-down transformer stations in the Barrie/Innisfil Sub-Region as follows:

Table 6-2 Step-Down Transformer Stations in Barrie/Innisfil Sub-Region

Station	DESN	Voltage Transformation
Alliston TS	T2/T3/T4	230/44kV
Barrie TS	T1/T2	115/44kV
Everett TS	T1/T2	230/44kV
Midhurst TS	T1/T2	230/44kV

Based on the LTR of these transformer stations, additional transformation capacity is required at Barrie TS (115/44kV) since the station exceeded its LTR in 2015. This will be addressed by the proposed replacement and upgrade of Barrie TS and circuits E3B/E4B (see details in Section 7.1). In 2031, the upgraded Barrie TS is forecasted to reach its capacity.[6] Since this is a long-term capacity need, it will be monitored and investigated further in the next cycle of the Regional Planning Process. The upgrade of Barrie TS will also address the InnPower distribution feeder capacity need that arises in 2020 – see Section 7.6 for more information.

Everett TS is expected to reach its LTR in approximately ten years. The station's LTR of 86 MW is presently limited by the tap ratio setting of the low voltage current transformers (CT). As the capacity need date approaches, the tap ratio will be increased and the capacity of the station will increase to the LTR of the transformers. The solution to address this capacity need is further described in Section 7.7.

The stations' actual non-coincident peaks, the associated station capacity, and need dates are summarized in Table 6-3.

[6] The LTR for the upgraded Barrie TS has been updated since the 2016 Barrie/Innisfil IRRP due to change in the planning LTR factor and changes in power factor assumptions. An increase of approximately 10.75 MW for the summer 10-day LTR (2.25 MW from the LTR factor change and 8.5 MW from the differing power factor assumptions) resulted in a deferral of the need date from 2026 (as indicated in the IRRP) to 2031 in the RIP report. As well, the IRRP forecast included an extreme weather correction which also contributes to the difference in need date.

Table 6-3 Transformation Capacities in the Barrie Innisfil Sub-Region

Station	LTR (MW)	2016 Summer Peak (MW)	Relief Required By
Alliston TS (T2)	100	118	-
Alliston TS (T3/T4)	101		-
Barrie TS (T1/T2)	109	102	Immediately
Barrie TS (uprated)	161.5[7]	102	The uprated Barrie TS will exceed its capacity by 2031
Everett TS (T1/T2)	86	70	2027
Midhurst TS (T1/T2)	163	105	-
Midhurst TS (T3/T4)	150	106	-

6.3 Parry Sound/Muskoka Sub-Region's Step-Down Transformer Station Facilities

There are five step-down transformer stations in the Parry Sound/Muskoka Sub-Region as follows:

Table 6-4 Step-Down Transformer Stations in Parry Sound Muskoka Sub-Region

Station	DESN	Voltage Transformation
Bracebridge TS	T1	230/44kV
Muskoka TS	T1/T2	230/44kV
Orillia TS	T1/T2	230/44kV
Parry Sound TS	T1/T2	230/44kV
Waubaushene TS	T5/T6	230/44kV

Under peak conditions in winters between 2013 and 2016, Parry Sound TS transformers supplied up to 6 MW over their LTR. Although the 2017 winter station peak only reached 44 MW (8 below LTR), the immediate addition of 44 kV capacity is required to provide relief to Parry Sound TS. Two alternatives to address this need are discussed further in Section 7.3.

Waubaushene TS is expected to exceed its LTR of 105 MW by 2027[8]. Plans to mitigate loading problems in Waubaushene TS are discussed in Section 7.7 as long-term needs.

---

[7] The LTR for the upgraded Barrie TS has been updated since the 2016 Barrie/Innisfil IRRP due to change in the planning LTR factor and changes in power factor assumptions. An increase of approximately 10.75 MW for the summer 10-day LTR (2.25 MW from the LTR factor change and 8.5 MW from the differing power factor assumptions) resulted in a deferral of the need date from 2026 (as indicated in the IRRP) to 2031 in the RIP report. As well, the IRRP forecast included an extreme weather correction which also contributes to the difference in need date.

[8] The LTR for Waubaushene TS has been updated since the 2016 PSM IRRP due to changes in power factor assumptions. For the 2016 PSM IRRP, it was assumed that all transformer stations have a 90% power factor. For the SGBM RIP, it was assumed that stations without low voltage capacitor banks have a 90% power factor and stations with low-voltage capacitor banks have a 95% power factor. Since Waubaushene TS has low voltage capacitor banks, the power factor was changed from 90% to 95% in the SGBM RIP, resulting in a higher LTR and a later need date as compared to the findings in the 2016 PSM IRRP.

Muskoka TS, Orillia TS and Bracebridge TS are adequate to meet the net demand over the study period.

The stations' actual non-coincident peaks, the associated station capacity, and need dates are summarized in Table 6-5.

Table 6-5 Transformation Capacities in the Parry Sound/Muskoka Sub-Region

Station	LTR (MW)	2017 Winter Peak (MW)	Relief Required By
Bracebridge TS (T1)	84	11	-
Muskoka TS (T1/T2)	198	145	-
Orillia TS (T1/T2)	177	115	-
Parry Sound TS (T1/T2)	52	44	Immediately
Waubaushene TS (T5/T6)	104[9]	81	2027

The winter and summer non-coincident load forecasts for all stations in the Region are given in Appendix C and Appendix D, respectively.

6.4 Areas outside of Sub-region

The table below lists the seven transformer stations that are outside of the Sub-regions

Table 6-6 Transformation Capacities in the Areas outside of Sub-Region

Station	DESN	Voltage Transformation
Beaverton TS	T3/T4	230/44kV
Lindsay TS	T1/T2	230/44kV
Meaford TS	T1/T2	115/44kV
Minden TS	T1/T2	230/44kV
Orangeville TS	T1/T2	230/44/27.6kV
Orangeville TS	T3/T4	230/44kV
Stayner TS	T3/T4	230/44kV
Wallace TS	T3/T4	230/44kV

[9] The LTR for Waubaushene TS has been updated since the 2016 PSM IRRP due to changes in power factor assumptions. For the 2016 PSM IRRP, it was assumed that all transformer stations have a 90% power factor. For the SGBM RIP, it was assumed that stations without low voltage capacitor banks have a 90% power factor and stations with low-voltage capacitor banks have a 95% power factor. Since Waubaushene TS has low voltage capacitor banks, the power factor was changed from 90% to 95% in the SGBM RIP, resulting in a higher LTR and a later need date as compared to the findings in the 2016 PSM IRRP..

Table 6-7 Transformation Capacities in the Areas outside of Sub-Region

Station	LTR (MW)	2017 Winter Peak (MW)	Relief Required By
Beaverton TS	213	72.2	-
Lindsay TS	183	76.6	-
Meaford TS	58	31.7	-
Minden TS	58	50.6	-
Orangeville TS (T1/T2) 27.6 kV	110	32	-
Orangeville TS (T1/T2) 44 kV	56	21	-
Orangeville TS (T3/T4)	118	71	-
Stayner TS	203	124.5	-
Wallace TS	54	33.3	-

Based on peak load conditions, all the transformers are within their respective LTRs.

End-of-Life Equipment Replacements

Recent station assessments have identified near-term end-of-life needs at Orangeville TS and Minden TS, and a recent condition assessment of Parry Sound TS has revealed that one of the existing power transformers at the station is in a very poor condition and must be replaced in the near-term.

- The Minden TS facility was originally built in 1950. Its assets are degrading in condition and require replacement in 2020-2021. Existing 230/44 kV T1 and T2 three-phase power transformers and associated ancillary equipment will be upgraded with the smallest available standard size 230/44 kV three-phase power transformers. As a result, the rating of transformers will increase from 25/33/42 to 50/66.7/83.3 MVA. See Section 7.8 for more information.

- Switchyards at Orangeville TS were placed in-service in 1960s and several of the assets are at the end of their useful lives including all four transformers (T1, T2, T3, and T4). In addition, the existing 210-44-28 kV winding configuration on T1 and T2 is non-standard which introduces challenges with maintenance, spare parts and future replacement strategies. The existing switchyard supplied by T1/T2 consists of 28kV feeders, plus additional two 44kV feeders.

  After reviewing different alternatives, the preferred solution is to replace T1/T2 with standard three-phase 215.5-28kV transformers, while T3 and T4 will be replaced with standard 215.5-44kV units. The existing 44kV feeders in the T1/T2 DESN will be relocated to the T3/T4 DESN. Due to this modification, the T3/T4 rating will change from 50/67/83 to 75/100/125 MVA, while the T1/T2 rating will change from 75/100/125 to 50/66.7/83.3 MVA. See Section 7.9 for more information.

- Parry Sound TS was placed in service in 1970 and has been supplying power to parts of the Region for almost 50 years. Field crews have recently observed that one of the two power transformers is in poor operating condition which has triggered a station assessment which will be undertaken by Hydro One's Station Sustainment team in 2017. The team will assess all of the Parry Sound TS equipment to determine when the various components need to be replaced in order to avoid end-of-life failures. See Section 7.3 for more information.

It is worth noting that there are potential bulk power system elements that are also at the end of their useful lives. These include 230 kV transmission lines D1M/D2M, E8V/E9V, and M6E/M7E. IESO will lead the bulk power system studies for these lines in coordination with Hydro One.

7. REGIONAL PLANS

THIS SECTION DISCUSSES THE NEEDS, WIRES ALTERNATIVES AND THE CURRENT PREFERRED WIRES SOLUTION FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS IN THE SOUTH GEORGIAN BAY/MUSKOKA REGION. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE IRRPS FOR THE BARRIE/INNISFIL AND THE PARRY SOUND/MUSKOKA SUB-REGIONS.

The near-term needs arise over the first five years of the study period (2016 to 2020) and the mid-term needs cover the second half of the study period (2021-2025).

7.1 Increase Transformation Capacity in Barrie/Innisfil Sub-Region

Description

The Barrie/Innisfil Sub-Region includes the areas supplied by Midhurst TS, Barrie TS, Everett TS, and Alliston TS, and transmission circuits E8V/E9V, E3B/E4B, and M6E/M7E.

Over the next 10 years, the load in this Sub-Region is forecasted to increase at a rate of approximately 2.5% annually.

Based on the net forecasts (DG and CDM incorporated) in the Sub-Region, adequate transformation capacity is available at Midhurst TS and Alliston TS to maintain reliable supply to meet the demand over the near and mid-term period.

Barrie TS is a summer-peaking station and currently exceeds its normal supply capacity based on both gross and net summer demand. Circuits E3B/E4B that supply radially to Barrie only are also approaching their LMC, which they are expected to exceed by 2019.

Everett TS has a long term need which is discussed in Section 7.7.

Recommended Plan and Current Status

During the regional planning process, the Study Team considered multiple alternatives to address the transformation capacity and end-of-life needs in this Sub-Region.

The 44 kV switchyard at Barrie TS was placed in-service in 1962 and the assets are in degraded condition and are in need of replacement. Previous assessments have suggested the replacement of aged and degraded infrastructure, including both transformer banks, low voltage switchgear, capacitor banks and associated ancillary equipment. Loading on the Barrie TS T1/T2 yard has steadily increased since 2013 and has reached a point where it is encroaching on the LTR rating of the transformer banks, and limiting further connections downstream from the station.

Since Barrie TS currently exceeds its supply capacity, the like-for-like option would not result in any increase in capacity. Instead it was proposed to remove T1/T2 (230/115kV) at Essa TS and replace T1/T2 (55/95MVA, 115/44kV) at Barrie TS with one pair of transformers T1/T2 (75/125MVA, 230/44kV) at Barrie TS, along with uprating circuits E3B/E4B from 115kV to 230 kV. This would increase the Barrie DESN capacity by 50MW, and increase the LMC of E3B/E4B as well.

The Study Team recommended to rebuild and uprate Barrie TS as the best solution to meet the transformation capacity need in the Sub-Region. Hydro One is currently developing this plan, called the 'Barrie Area Transmission Upgrade project'. Class Environmental Assessment (EA) is in progress for this project. Since circuits E3B and E4B are 9km in length, an OEB Section 92 approval is required for this project. It will be initiated once the engineering estimate is completed for this project by early 2018.

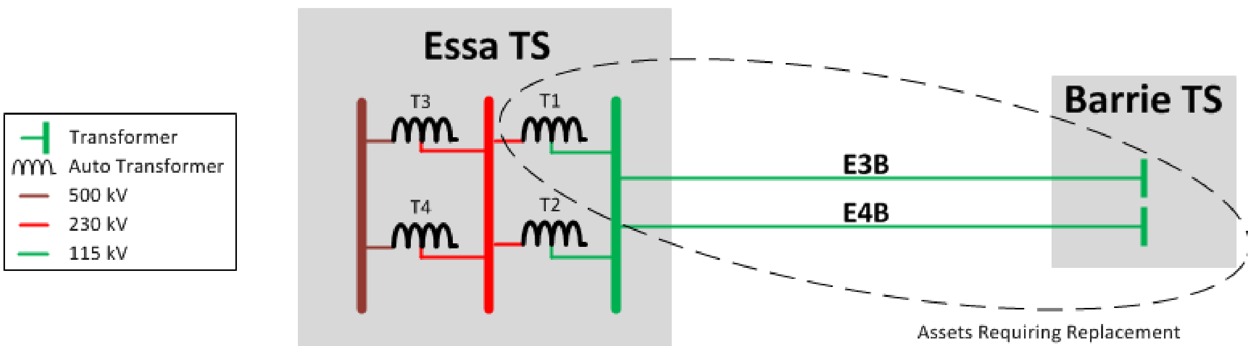

Figure 7-1 Current Arrangement of Essa TS, Barrie TS, and Circuits E3B/E4B

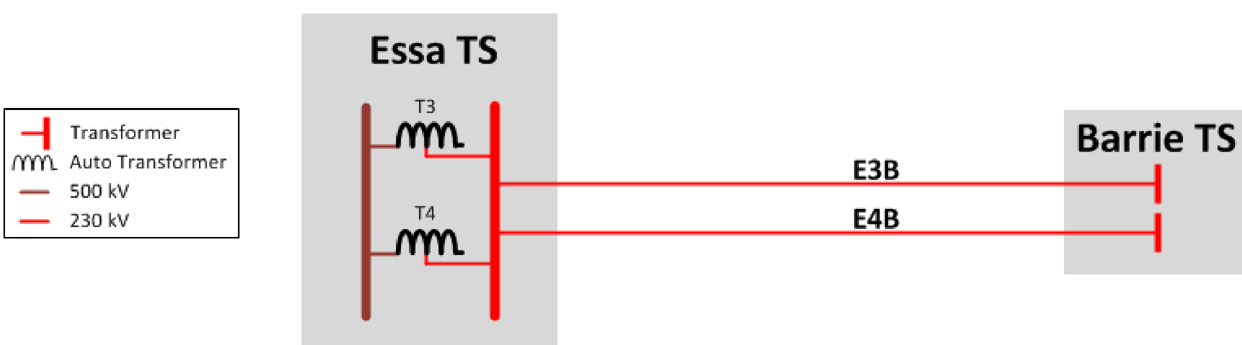

Figure 7-2 New Configuration of Essa/Barrie Supply to Barrie DESN

The total cost of this project is estimated to be $84M. This estimate includes the cost of transmission as well as distribution investments which include the station's construction, its connection arrangements as defined above, and feeder egress to the distribution risers outside of the station.

7.2 Transformation Capacity Need at Uprated Barrie TS

Description

Over the 20 year planning period, Barrie TS will experience the biggest growth out of all the transformer stations, which is influenced by the recent continued development of data centers in the City Of Barrie, and greenfield residential development in the annexed lands in south Barrie, in addition to the proposed industrial and commercial development at Innisfil Heights near Highway 400. With the forecast data collected, it is determined that the uprated Barrie TS will exceed its LTR by 2031.

Proposed Alternatives and Recommended Plan

One of the alternatives to accommodate load growth in Barrie/Innisfil Sub-Region, is to build a new 230 kV station via the idle Hydro One right-of-way, a corridor currently being utilized by the existing 13M3 feeder, which could provide an additional 150MW capacity.

The additional feeders that are being built by Alectra will facilitate the transfer of up to 27 MW of load from Barrie TS to Midhurst TS by 2019 and will defer a capacity need at the upgraded Barrie TS to 2031. This need will be monitored and investigated further in the next cycle of the Regional Planning Process. Long-term options beyond 2026 are discussed in Section 7.7.

7.3 Increase Transformation Capacity in Parry Sound/Muskoka Sub-Region

Description

The load forecast reflects an annual growth of 0.82 % in Parry Sound/Muskoka area throughout the study period.

Based on historical demand data and the station's net demand forecast, Parry Sound TS T1/T2 has already exceeded its respective normal supply capacity and will continue to do so over the study period. Parry Sound TS is a winter peaking station with a winter LTR of 52 MW. It had exceeded its LTR by as much as 6 MW in the winters of 2013 to 2016, however the 2017 winter peak was 8 MW below the LTR.

Waubaushene TS is expected to be loaded beyond its winter LTR (104.5 MW) by 2026-27. Recommended plans for addressing this need are discussed in Section 7.7. Although the summer peak is not expected to exceed the summer LTR over the study period based on the net demand forecast, historical summer peak demand (2015/2016) at Waubaushene TS was approaching the summer LTR. The

Study Team will continue to monitor the summer and winter demand closely and explore opportunities to manage the peak demand growth at Waubaushene TS.

Therefore, based on the current load forecasts, additional transformation capacity relief is required for both Parry Sound TS and Waubaushene TS to accommodate the load growth and improve reliability in this sub-region.

Recommended Plan and Current Status

There are two options that have been proposed to address the capacity need at Parry Sound TS: a) Distribution load transfer and b) upsize transformers at Parry Sound TS.

Option a) To accommodate the load growth at Parry Sound TS, 6 MW of Parry Sound's load can be transferred over to Muskoka TS. For this load transfer to take place, Hydro One Distribution will need to seek approval to construct a new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS, which would cost approximately $7M and would be in service by 2020. This option will address the near term supply needs at Parry Sound TS.

Option b) Hydro One has identified that Parry Sound TS (T1/T2) transformer T2 is in poor condition and must be replaced in the near-term. The second transformer is also identified to be reaching the end of its useful life over the next 5-10 years. As a result, Hydro One is planning to replace T2 which is a non-standard 25/42 MVA, 230/44 kV transformer with a 50/83 MVA unit which is currently the smallest standard size transformer at this voltage level. In addition, Hydro One will also consider advancing the replacement of the companion transformer, T1, since it will be much more efficient and economical to replace both transformers at the same time. The additional cost to replace T1 is approximately $8M. This would address the near- and long-term capacity need at Parry Sound TS; eliminate the need to spend $7M on the 44 kV sub-transmission line; and provide better reliability for customers. The advancement cost of replacing T1 is approximately $2M. The new transformers at Parry Sound TS would be expected in service by 2021.

Since the peak demand growth is relatively slow in this area, conservation and local demand management and distributed generation can be used in the meantime to defer capacity-related upgrades at these stations. Results from the Parry Sound/Muskoka Local Achievable Potential ("LAP") study can help the Study Team better understand cost and feasibility of using distributed energy resources and local demand management options to manage electricity demand growth in the area.

Going forward, the Study Team will need to assess the cost-benefit of the various options to address supply capacity needs at Parry Sound TS and to determine whether it would be cost-effective to advance the replacement of the companion transformer, T1, at Parry Sound TS at this time. The decision related to the end of life replacement of the transformers at Parry Sound TS will need to be made by mid-2018 so that the transformers can come into service by early 2021.

With the future increased station capacity at Parry Sound TS, the long-term capacity need at Waubaushene TS could be addressed via permanent load transfers since transfer capability already exists between the two stations.

7.4 Parry Sound/Muskoka Load Restoration Assessment

Description

The Parry Sound/Muskoka load restoration need was identified in the Parry Sound/Muskoka Sub-Region IRRP report, which indicated that for the loss of two transmission elements (M7E/M6E transmission lines) the load interrupted with current circuit configuration during peak periods will exceed load restoration criteria.

M6E/M7E transmission lines currently supply 465 MW of peak demand. In the event of a double circuit outage, all customers on this double circuit will be interrupted for more than 30 minutes. As per ORTAC criteria, this constitutes a violation unless 215 MW of peak load can be restored within 30 minutes for a M76/M7E outage during a peak demand period.

Proposed Alternatives and Recommended Plan

In collaboration with the Study Team, a recommendation for the load restoration was identified in the Region. One of the alternatives considered was resupplying load from the 44 kV system. However, this will only supply about 20-30 MW.

The Study Team is recommending that an investment in motorized disconnect switches (MDS) should be made, which can be used to isolate sections of the transmission lines within 30 minutes. These switches would be installed at the Orillia TS junction. Another alternate solution was installing breakers on the line instead of motorized switches, since breakers can immediately isolate a section faulted line.

Breakers would be useful if the loading on the double circuit was more than 600 MW, however given the uncertainty of future load growth and the cost of breakers which are 3-4 times more expensive than motorized switches, the Study Team recommended to proceed with the installation of two 230 kV motorized switches at Orillia TS. The switches will be in service by 2021 at a cost of $5-7M.

In the event of a double M6E/M7E outage, with the motorized disconnect switches installed, at least 50% of the load on this double circuit supply can be restored within 30 minutes, meeting the ORTAC 30 minute load restoration criteria.

IESO has issued a hand-off letter to Hydro One to initiate the development work for the installation of motorized disconnect switches at Orillia TS. The development work is currently underway, in the budgetary estimating phase.

7.5 Outage Duration And Frequency in Parry Sound/Muskoka Sub-Region

Description

Load in the Parry Sound/Muskoka Sub-Region is supplied via:

- Local generation resources;
- 230 kV transmission system;
- 44 kV sub-transmission and low-voltage distribution system.

Customers supplied by Muskoka TS and Parry Sound TS in this sub-region experience more frequent and prolonged outages, almost double the provincial performance, which can impede economic development. Most of the incidents occur on the 44kV sub-transmission system due to longer feeder length as compared to the average length of feeders in the rest of the province. Longer lines increase exposure to tree contact and require additional time for repair crews to identify and isolate faulted sections.

Recommended Plan and Current Status

Hydro One Distribution currently has a number of on-going maintenance and outage mitigation initiatives. These are listed below:

- Vegetation Management Program
- Line Patrols
- Mid-cycle Hazard Tree Program
- Distribution Management System and Grid Modernization

In addition, Hydro One Distribution will assess other options as well and provide an update to the communities and LACs on plans to improve the 44 kV system by the end of 2017.

Another option to mitigate outages on the 44 kV is to build new distribution lines from Bracebridge TS, and transfer some load over to Bracebridge TS, since currently the industrial load demand at that station has been decreasing over the last several years.

Cost-Benefit/Responsibility will be considered by Hydro One Distribution, Lakeland Power and Veridian Connections to improve reliability performance of the 44 kV sub-transmission system, which will be completed by the end of 2017.

7.6 Distribution Feeder Capacity to Supply InnPower

Description

Currently six feeders in Barrie TS are used to supply Alectra, and one feeder supplies InnPower. From the forecast provided, the Study Team concluded in the IRRP that InnPower will exceed its load capacity of

25 MW, which its existing feeder can supply, by 2020. An additional feeder will be required for InnPower starting 2020.

Recommended Plan and Current Status

The uprated Barrie TS will include eight feeders, as opposed to the current seven feeders that exist today. This additional feeder can be used in addition to the existing InnPower dedicated feeder to supply InnPower load.

7.7 Long Term Regional Plan

As discussed in Section 5, the electricity demand in South Georgian Bay/Muskoka Region is forecasted to grow at 1.46% annually over the next 10 years, and at a slightly lower average rate of 1.17% from 2016-2034. Similar trend is also expected in the long term period where the load is expected to increase by approximately 1% annually from year 2024 to 2034 in the Parry Sound/Muskoka Sub-Region, while 1.9% in the Barrie/Innisfil Sub-Region. Long term forecast provides a high level insight of how the region may be developing in the future so that near and mid-term plans and ongoing projects in the region are best aligned with potential long term needs and solutions.

Parry Sound/Muskoka

Currently the Muskoka-Orillia 230kV subsystem supplies up to 454 MW. Based on electricity demand growth, Muskoka-Orillia is not expected to exceed its LMC of 600 MW until early 2030.

The following options will be revisited in the next regional planning cycle:

- Upgrade the transmission lines in the area, thus increasing M6E/M7E LMC.
- Connect a 20 MW generation on the Muskoka-Orillia 230 kV system
- Results from the Parry Sound/Muskoka LAP study can help the Study Team better understand cost and feasibility of using distributed energy resources and local demand management options to manage electricity demand growth in the area.

Electricity demand forecast is expected to exceed Waubaushene TS system's capability by 2026-27. To manage this long term growth, 4MW load can be transferred from Waubaushene TS to Orillia TS. More transfer capability between Waubaushene TS and Midhurst TS will be available upon completion of 'Barrie Area Transmission Upgrade' project. With the potential increase of the capacity at Parry Sound TS, there will be capability to transfer additional load from Waubaushene TS to Parry Sound TS.

Barrie/Innisfil

Barrie/Innisfil sub region is the area supplied by Midhurst TS, Barrie TS, Alliston TS, and Everett TS. The planning load forecast projects that load will exceed the aggregate capacity of these transformers by

2033. Due to the uncertainty of long term forecasts, IESO will monitor the area and an annual update to the Study Team on demand, conservation and DG trends.

Everett TS is forecasted to exceed its LTR (86.4 MW) by 2026. This LTR is currently limited by the CT ratio. Hydro One is now able to update CT ratio whenever desired which would increase the LTR. The new LTR may defer the capacity need at Everett TS beyond the study period.

In the Barrie area, load is expected to exceed the area's LMC (Midhurst TS and Barrie TS capacity) by 2031. Alectra Utilities and InnPower will undertake a LAP study to address the long term needs for Barrie TS service area to determine the conservation and demand management potential in the area beyond the conservation values already accounted for in the planning forecast.

Metrolinx is planning to electrify the Barrie GO train lines and has approached Hydro One, requesting 40-50MW of capacity. The new 230kV circuits from Essa TS to Barrie TS would provide adequate capacity and tapping positions for Metrolinx's substation, however the supply capacity at Essa TS may present some limitations. Therefore the Metrolinx project is being closely monitored by the IESO and Study Team.

7.8 Minden TS End of Life Assets

Description

The Minden T1/T2 yard is a unique DESN which transforms voltages from 230 kV to 44 kV and facilitates load delivery to the Minden area via four (4) feeders supplying the Hydro One distribution system. This station was built in the 1950s and is primarily composed of older equipment. The T1 and T2 transformers are each rated at 25/42 MVA and are non-standard as per the current standards. Non-standard and obsolete equipment introduces complexities in repairing failures and difficulties in finding and installing spare equipment. The transformers are currently beyond their expected service life and their condition is deteriorating and leak risk is increasing. Furthermore, due to the station's unique configuration, an outage on the high voltage bus or a transformer will cause load loss, which does not occur in a standard DESN layout.

Alternatives and Recommended Plan

The following alternatives were considered to address the end of life situation at Minden TS:

- Maintain Status Quo ("do nothing"): This alternative was considered and rejected as it does not address the risk of failure due to aging equipment and would result in increased maintenance expenses and reduced supply reliability for customers.
- Like-for-Like replacement of assets: This alternative would require the purchase and installation of custom, non-standard, 25/42 MVA transformers and associated equipment which is not justifiable based on the load forecast and would cost more than the smallest standard 230/44 kV transformers which are 50/83 MVA.

- Replace transformers with standard 50/83 MVA units and reconfigure switchyard: This alternative will include replacing the existing transformers with 50/83 MVA units and reconfiguring part of the switchyard to meet standard DESN layout and improve supply reliability to customers.

The preferred alternative is for Hydro One to replace the existing transformers with standard 50/83 MVA units and reconfigure the switchyard to allow it to operate the way a standard DESN should. The new equipment is expected to have a service life of over 50 years and will be able to supply the forecasted load growth in the Minden area. This option allows for easy installation of spare equipment in case failures occur and the improved reliability will improve the customer satisfaction in the area. This refurbishment project is currently planned to be completed in 2020-2021 at a cost of $17 million.

7.9 Orangeville TS End of Life Assets

Description

Orangeville TS is a transmission station that provides 230 kV switching as well as transformation of 230 kV to 44 kV and 27.6 kV. Orangeville TS serves as the supply for Hydro One Distribution and Orangeville Hydro customers in and around the town of Orangeville via two DESN switchyards, T1/T2 (27.6 and 44 kV) and T3/T4 (44 kV). The 27.6 kV and 44 kV switchyards were placed in-service in 1969 and many assets are in a degraded condition and in need of replacement. Previous assessments have identified that all four transformers T1, T2, T3, and T4 and associated equipment are candidates for replacement. In addition, the existing 210-44-28 kV winding configuration on T1 and T2 is non-standard, which introduces challenges with maintenance, sparing and future replacement strategies.

In recent discussions, Orangeville Hydro expressed its intent to further increase its use of the 27.6 kV feeders supplied from Orangeville TS. Consequently, Orangeville Hydro intends to reduce the number of customers and stations connected to the 44 kV feeders M3 and M5.

Alternatives and Recommended Plan

The following alternatives were considered to address the end of life issue at Orangeville TS:

- Maintain Status Quo (“do nothing”): This alternative was considered and rejected as it does not address the risk of failure due to aging equipment and would result in increased maintenance expenses and reduced supply reliability for customers.
- Like-for-Like replacement of assets: This alternative would require the purchase and installation of custom, non-standard, transformers and associated equipment which is not justifiable based on the cost of custom equipment, Orangeville Hydro’s supply voltage plans, and Hydro One’s effort to standardize non-standard station configurations.
- Replace transformers with standard units and reconfigure 27.6 kV and 44 kV switchyards: This alternative aims to replace the existing T1/T2 transformers with standard units, standardize the configuration of the T1/T2 switchyard by converting it to a typical 230/27.6 kV DESN, replace

the aging T3/T4 230/44 kV transformers to maintain overall 44 kV capacity, and relocate 44 kV feeders to the new T3/T4 DESN.

The preferred alternative is for Hydro One to replace the existing T1/T2 230/44/27.6 kV 75/125 MVA transformers with two 230/27.6 kV 50/83 MVA units and reconfigure the dual voltage switchyard to a standard DESN that would supply the 27.6 kV load. Hydro One will also replace the existing T3/T4 230/44 kV 50/83 MVA transformers with two 230/44 kV 75/125 MVA units to accommodate the additional capacity required by the relocation of the two 44 kV feeders. This alternative will address the need to replace end-of-life transformers T1/T2/T3/T4 and associated equipment as well as associated end-of-life protection, control and telecom assets. It will allow Hydro One to standardize the DESN layout, simplify equipment maintenance and installation in case of a failure, and reliably supply the forecasted demand for the area. This refurbishment project is currently planned to be completed in 2024-2025 at a cost of $33 million.

8. CONCLUSION AND NEXT STEPS

THIS RIP REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE SOUTH GEORGIAN BAY-MUSKOKA REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in Table 8-1.

Table 8-1 Regional Plans – Needs Identified in the Regional Planning Process

Need ID	Needs	Timing
I	Additional transformation capacity for 115kV Barrie TS	Today
II	Additional transformation capacity for the uprated 230kV Barrie TS	Long-term[10]
III	Additional transformation capacity for Parry Sound TS	Today
IV	Transmission Line Capacity for E3B/E4B	2019
V	Load restoration for loss of M6E/M7E	Today
VI	Mitigate frequency and duration of outages on the 44kV Parry Sound/Muskoka sub-region	Today
VII	Additional feeder position for InnPower supplied from Barrie TS	2020
VIII	Additional capacity required for Barrie/Innisfil Sub-Region and Barrie sub-area	Long-term
IX	Additional transformation capacity for Waubaushene TS	Long-term[11]
X	Additional transformation capacity for Everett TS	Long-term
XI	LMC and Load Security for M6E/M7E	Long-term

Projects, lead responsibility, and timeframes for implementing the wires solutions for the above needs are summarized in Table 8-2 below.

[10] The LTR for the upgraded Barrie TS has been updated since the 2016 Barrie/Innisfil IRRP due to change in the planning LTR factor and changes in power factor assumptions. An increase of approximately 10.75 MW for the summer 10-day LTR (2.25 MW from the LTR factor change and 8.5 MW from the differing power factor assumptions) resulted in a deferral of the need date from 2026 (as indicated in the IRRP) to 2031 in the RIP report. As well, the IRRP forecast included an extreme weather correction which also contributes to the difference in need date.

[11] The LTR for Waubaushene TS has been updated since the 2016 PSM IRRP due to changes in power factor assumptions. For the 2016 PSM IRRP, it was assumed that all transformer stations have a 90% power factor. For the SGBM RIP, it was assumed that stations without low voltage capacity banks have a 90% power factor and stations with low-voltage capacity banks have a 95% power factor. Since Waubaushene TS has low voltage capacity banks, the power factor was changed from 90% to 95% in the SGBM RIP, resulting in a higher LTR and a later need date as compared to the findings in the 2016 PSM IRRP.

Table 8-2 Regional Plans – Projects, Lead Responsibility, and Planned In-Service Dates

Project	Lead Responsibility	I/S Date	Cost	Need Mitigated
Replacement of 115/44 kV transformers (T1 and T2) at Barrie TS, uprating 115 kV circuits E3B/E4B to 230 kV, adding additional feeder to Barrie DESN	Hydro One	2020	$84M	I, IV, VII
Replacement of 230/44 kV transformers (T1 and T2) and possible rebuild of low voltage switchyard at Minden TS	Hydro One	2020-2021	$17M	End-of-Life
Installation of sectionalizing motorized disconnect switches on circuits M6E/M7E (at Orillia TS)	Hydro One	2021	$5-7M	V
Build new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS*	Hydro One	2020	$7M	III
Replacement of 230/44 kV transformers at Parry Sound TS*	Hydro One	2021	$20M	End-of-Life, III
Replacement of Orangeville TS transformers and associated low voltage equipment, and reconfiguration of low voltage switchyards	Hydro One	2024-2025	$33M	End-of-Life

* Replacement of transformers at Parry Sound TS would eliminate the need to build new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS

For the Need III, Parry Sound/Muskoka Local Achievable Potential ("LAP") study will be initiated shortly to help the Study Team better understand cost and feasibility of using distributed energy resources and local demand management options to manage the electricity demand growth in the area. Furthermore, the Study Team will need to assess the cost-benefits of the various options to address supply capacity needs at Parry Sound TS and to determine whether it would be cost-effective to advance the replacement of the companion transformers at Parry Sound TS at this time. The decision related to the end of life replacement of the transformers at Parry Sound TS will need to be made by mid-2018 so that the transformers can come into service by early 2020s.

For Need VI, cost-benefit/responsibility analysis will be considered by Hydro One Distribution, Lakeland Power and Veridian Connections to improve reliability performance of the Parry Sound/Muskoka 44 kV sub-transmission system, which will be completed by the end of 2017.

Barrie/Innisfil Sub-Region and Barrie sub-area needs (Need VIII) has been reviewed in this Regional Planning cycle and "status quo/do nothing" course of action has been recommended for the time being, while the IESO and the Study Team will continue to monitor load growth in the area and determine the conservation and demand management potential in the area.

As described in Section 7.7, no investment is required at this time to address the long-term needs II, IX, X, and XI. Further developments in the Region will be monitored and the need will be reviewed again as part of the next planning cycle.

In accordance with the Regional Planning process, the Regional Planning cycle will be triggered at least once within five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Sudbury/Algoma Region

Regional Infrastructure Plan ("RIP")

June 10th, 2016

Greater Sudbury Hydro Inc.
Hydro One Networks Inc. (Distribution)

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden.

The Needs Assessment ("NA") for the Sudbury/Algoma region was completed in March, 2015 (see attached) and the report recommends that no further coordinated regional planning is required to address needs in the Sudbury-Algoma Region.

To address local needs, local planning was undertaken by Hydro One Networks Inc. (Transmitter) and Hydro One Networks Inc. (Distribution) to address the "Manitoulin TS Low Voltage Regulation" need. A Local Planning ("LP") report was prepared and published by the Working Group for the Sudbury/Algoma region in September, 2015 (also attached).

The only major project planned for the Sudbury/Algoma Region over the near and mid-term is

- New 230/44kV station at Hanmer Ts to replace Coniston Ts (115/22kV). As part of this project, Coniston loads will be converted from 22kV to 44kV (2019). The approximate cost of this work is $25M. This is a pool funded investment.

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no further regional coordination was required, the attached NA and LP reports will be deemed to form the ("RIP") for the Sudbury/Algoma Region.

The next planning cycle for the region will take place within five years of the start of this cycle (2013) or earlier, should there be a new need identified in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

LOCAL PLANNING REPORT

Manitoulin TS Low Voltage Regulation
Region: Sudbury-Algoma

Revision: Final
Date: September 30, 2015

Prepared by: Hydro One Networks Inc (Transmission & Distribution)

Study Team	
Organization	Name
Hydro One Networks Inc. (Lead Transmitter)	Kirpal Bahra
Hydro One Networks Inc. (Distribution)	Richard Shannon

Disclaimer

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the Sudbury-Algoma Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	Sudbury to Algoma (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 20, 2014	**END DATE**	September 30, 2015

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the Sudbury-Algoma Region dated March 12, 2015. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

Based on Section 6 of the NA report, the study team recommended that no further coordinated regional planning is required to address the needs in the Sudbury-Algoma region. These needs are local in nature and will be addressed by wires options through local planning led by Hydro One with participation of the impacted LDC.

2. LOCAL NEEDS ADDRESSED IN THIS REPORT

The Manitoulin TS Voltage Regulation is a local need addressed in this report.

3. OPTIONS CONSIDERED

Hydro One (Transmitter) and Hydro One Distribution (LDC) have considered addressing the above need with the following options;

Alternative 0 – Status Quo.
Alternative 1 - Install 44kV Capacitor Bank at Manitoulin TS
Alternative 2 - Install 115kV Capacitor Bank at Manitoulin TS

See Section 3 for further detail.

4. PREFERRED SOLUTION

The preferred solution at this time is Alternative 0 – Status Quo. See Section 4 for details.

5. NEXT STEPS

The next steps are summarized in section 5

Table of Contents

1 INTRODUCTION

The Needs Assessment (NA) for the Sudbury/Algoma ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address some specific station capacity needs. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the Sudbury-Algoma Region over the next ten years (2014 to 2023) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

1.1 Sudbury to Algoma Region Description and Connection Configuration

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden. The boundaries of the Sudbury to Algoma Region are shown below in Figure 1.

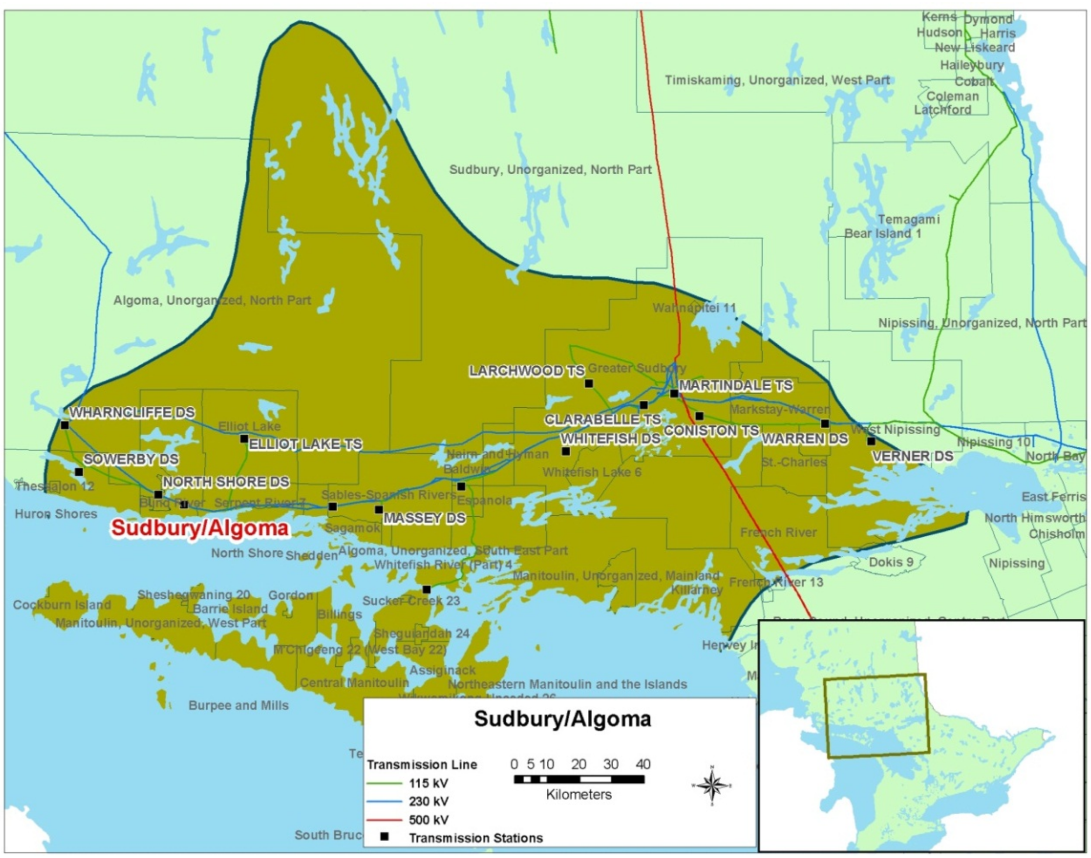

Figure 1: Sudbury to Algoma Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied by autotransformers at Hanmer TS, Algoma TS and Martindale TS. This area is further reinforced through the 500kV circuits (P502X and X504/503E) connecting Hanmer TS (Sudbury) to both Porcupine TS (Timmins) and Essa TS (Barrie). It is also connected to Northwest Ontario through Mississagi TS. Table 2 below lists the major transmission circuits and Hydro One stations in the subject region.

This region has the following two local distribution companies (LDC):

- Greater Sudbury Hydro Inc.
- Hydro One Networks Inc. (Distribution)

Espanola Regional Hydro Distribution is a third LDC in this region embedded into the Hydro One Distribution system. Although invited, this LDC opted not to participate in the Study Team. However, the interests of this LDC were communicated and considered through Hydro One Distribution as a host LDC.

Transmission connected loads in the Sudbury to Algoma region form a large percentage (approximately 50%) of the overall demand. Although these customers are not explicitly participating in the regional planning process, Hydro One considered their impact in this analysis.

115kV circuits	230kV circuits	Hydro One Transformer Stations
S6F,S5M	X74P, X27A	ALGOMA TS
S2B,B4B	A23P, A24P	MARTINDALE TS
T1B, B3E	X23N, S21N	HANMER TS
B4E, L1S	X25S, X26S	CONISTON TS
	S22A	CLARABELLE TS
		ELLIOT LAKE TS
		ESPANOLA TS
		LARCHWOOD TS
		MANITOULIN TS

Table 1: Transmission Lines and Stations in Sudbury to Algoma Region

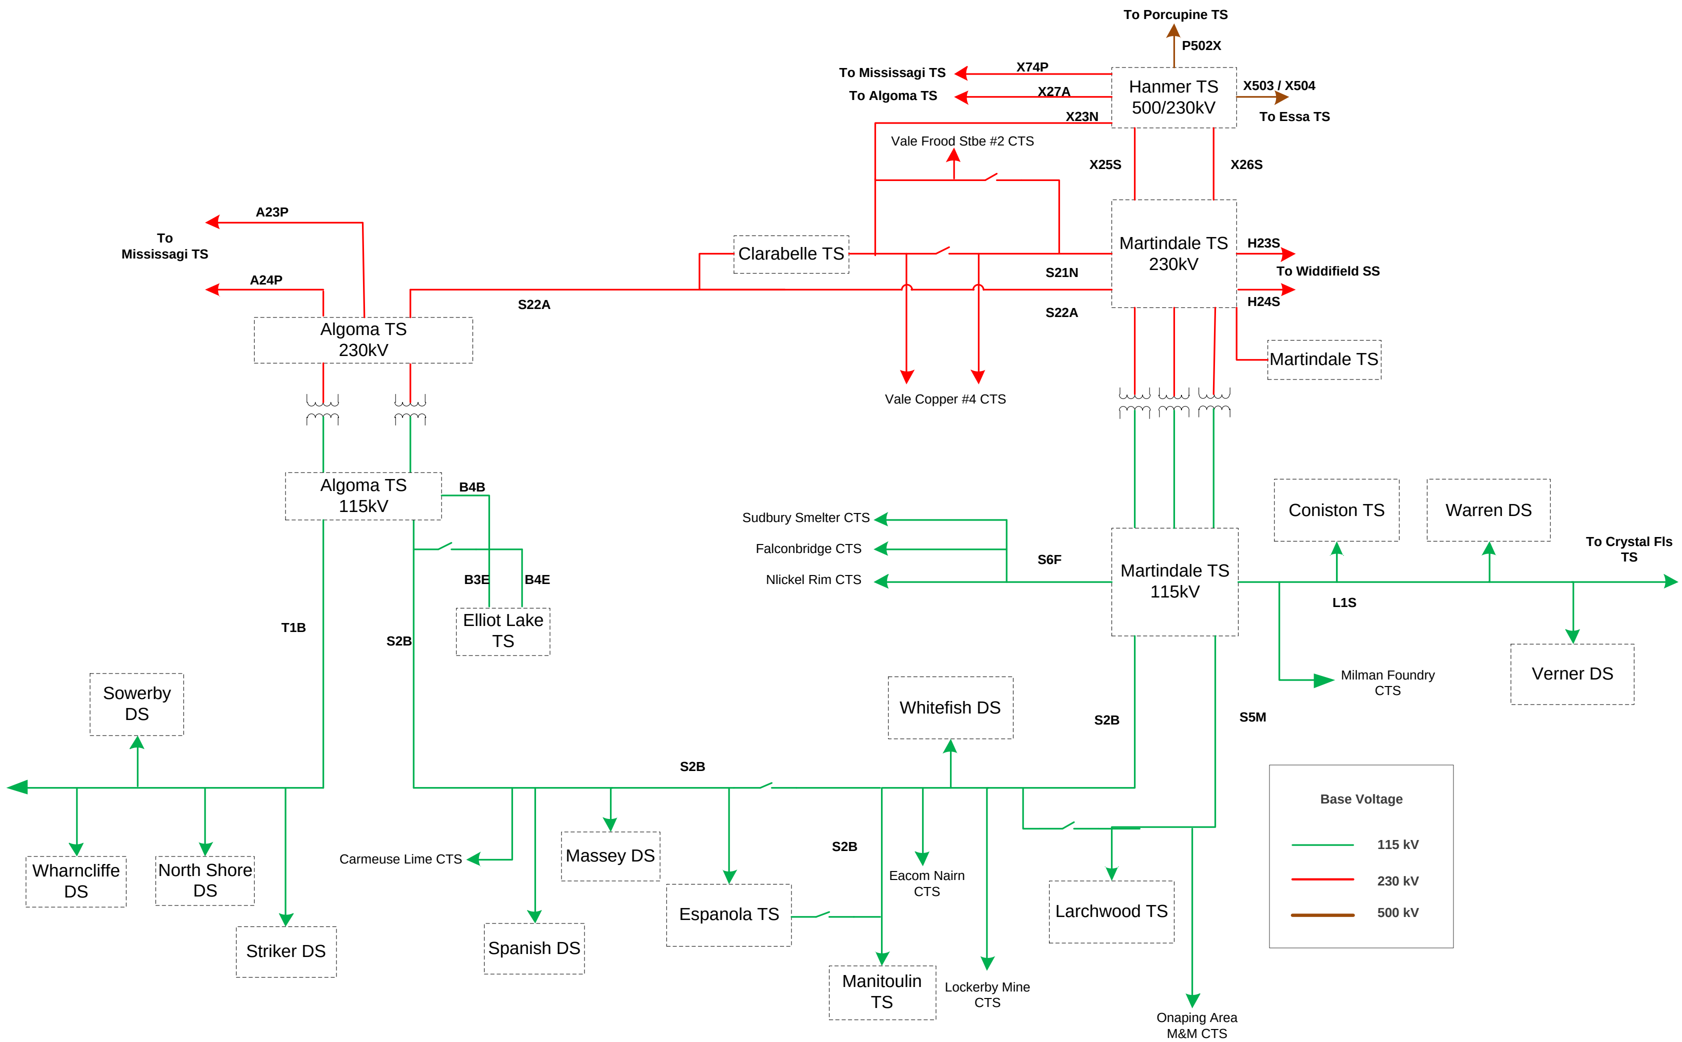

Figure 2: Single Line Diagram – Sudbury to Algoma Region

2 AREA NEEDS

2.1 Sudbury-Algoma Region Needs

As an outcome of the NA process, the study team did not identify any capacity needs based on LDCs load forecast. Only need identified was an issue with potential voltage regulation at Manitoulin TS in the Sudbury-Algoma Region to be addressed by a “localized” wires planning. Where local planning was recommended to address the needs, Hydro One, as transmitter, with the impacted LDC, further undertook planning assessments to address the need.

2.2 Needs Assessed by Hydro One led Local Planning

- Manitoulin TS Voltage Regulation – pre-contingency voltages at Manitoulin TS 115kV can at times fall below the ORTAC criteria of 113kV. Without McLean’s mountain wind farm in service, and under peak load conditions, pre-contingency voltage at Manitoulin TS high voltage bus can be as low as 110kV when supplied from Algoma TS, and 112kV when supplied from Martindale TS.

3 ALTERNATIVES CONSIDERED

Hydro One transmission reviewed the above need and determined that the only LDC impacted by a low voltage at Manitoulin TS is Hydro One distribution which is directly supplied at the stations’ 44kV bus. Following options were considered to address the needs identified in section 2 above.

Alternative 1 – Status Quo.

No further action is required at this time. Hydro One and LDC will monitor the load and voltages over the next three years. Further review will be undertaken in the next planning cycle or earlier if there is any evidence where load cannot be served or system cannot be operated in a safe, secure and reliable manner.

Alternative 2 – Install 44kV Capacitor Bank at Manitoulin TS

A 7MX low voltage capacitor bank can help improve high voltages regulation at Manitoulin TS. Manitoulin TS has a non-standard low voltage switch yard arrangement whereby each of the two feeders is supplied from a dedicated bus and associated transformer. There is currently no tie breaker between the two 44kV buses and thus, two 5.4MX capacitor banks will be required (for each of the busses). See figure 3.

Alternative 3 – Install 115kV Capacitor Bank at Manitoulin TS

A high voltage capacitor bank would also regulate the high voltage bus at Manitoulin TS. This alternative would require two high voltage breakers, and a motorized disconnect switch. See figure 4. Further investigation into this alternative indicated that 96MX capacitor bank is the smallest size available at this voltage. This large capacitor size would cause large voltage changes during switching and would violate operational criteria. Although this aspect would rule out this alternative it is shown illustration purposes in Table 3.

Table 3 below provides a budgetary cost summary of a cost of all options.

Options Considered	Cost
Alternative 1 – Hydro One to assess voltage performance of 115kV and 44kV bus with no immediate investment.	--
Alternative 2 – Install 44kV Capacitor Bank at Manitoulin TS	$4M
Alternative 3 – Install 115kV Capacitor Bank at Manitoulin TS	$6M

Table 2 – Budgetary Cost for Alternatives

4 PREFERRED SOLUTION AND REASONING

Hydro One Networks and the LDC have reviewed all alternatives and the preferred solution at this time is, Alternative 1 – Status Quo.

The study team acknowledges that the Manitoulin TS HV bus may experience voltages below ORTAC requirements only during limited operating scenarios. These scenarios are infrequent and the impacts of a low voltage at this point does not affect system stability or result in low voltages issues beyond the Manitoulin TS and Hydro One Distribution (LDC)

Manitoulin TS power transformers (T3/T4) are presently equipped with under load tap changers which have the ability to maintain 44kV bus voltages for wide array of voltage variations on the 115kV bus. ULTC ratings for both T3 and T4 are 44kV +/- 20% on 115.5kV at 42MVA load. These ratings are sufficient to maintain a customer delivery point performance within the rules of the Transmission System Code. The 44kV bus voltage will be maintained within 1.06 and 0.98pu for a 110kV (or lower) voltage.

Manitoulin TS voltage is constantly monitored by Hydro One's Ontario Grid Control Centre (OGCC) . OGCC's records will be reviewed regularly to ascertain the system conditions during peak load and its ability to operate the system and supply load to Manitoulin TS at acceptable voltage.

Voltage history will be reviewed with the LDC to determine if 44kV supply voltage remains within acceptable range for all distributed connected customers. The next planning cycle will take place within five years and an investment can be triggered at any time should there be a situation where load cannot be served or system cannot be operated safely and reliably.

5 NEXT STEPS

A summary of the next steps, actions/solutions and timelines required to address the local needs are as follows:

Need	Action / Recommended Solution	Lead Responsibility	Timeframe
Low Voltage at Manitoulin 115kV bus	• Status Quo –standard five year cycle	Hydro One Networks	Maximum five years

Table 3: Solutions and Timeframe

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Sudbury Algoma region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Sudbury to Algoma (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 20, 2014	**END DATE**	March 20, 2015

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the Sudbury to Algoma Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the Sudbury Algoma Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Sudbury Algoma Region belongs to Group 2. The NA for this Region was triggered on October 20, 2014 and was completed on March 20, 2015.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to the next 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2023. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the Independent Electricity System Operator (IESO), and Hydro One transmission provided information for the Sudbury Algoma Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2014 to 2023). The assessment reviewed available information and load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Needs

A. 230/115 kV Autotransformers

- The 230/115 kV autotransformers (Algoma TS, Martindale TS, Hanmer TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

B. 230 kV Transmission Lines

- The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

C. 115kV Transmission Lines

- The 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.
-

D. 230 kV and 115 kV Connection Facilities

- The 230k and 115kV connection facilities in this region are adequate over the study period.

E. Pre-contingency voltages at Manitoulin TS

- Under peak load conditions, pre-contingency voltages at Manitoulin TS 115kV bus can be below 113 kV.

System Reliability, Operation and Restoration Review

Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period. For the loss of one or two elements, the load interrupted by configuration does not exceed 150 MW or 250 MW. In addition,

- As identified by the IESO, under peak load conditions, the loss of two Martindale TS 230/115kV transformers may result in the overload of the third Martindale transformer.
- As identified by the IESO, With either X25S or X26S is out of service, the loss of the companion circuit may result in voltage declines at Martindale 230kV and 115kV buses below acceptable ORTAC limits.

The above issues will be further assessed as part of bulk system planning outside of the regional planning process.

Aging Infrastructure / Replacement Plan

Replacement of the autotransformers at Martindale is currently in Hydro One's 5yr sustainment business plan. As part of this replacement, T21/T23 autotransformer replacement at Martindale TS may result in higher emergency ratings.

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that no further regional coordination is required and following needs identified in Section 6 be further assessed as part of Local Planning:

Manitoulin TS Voltage Regulation

- Low pre-contingency voltages at Manitoulin TS 115kV bus.

TABLE OF CONTENTS

LIST OF FIGURES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the Sudbury to Algoma Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the Sudbury to Algoma Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. If localized wires only solutions do not require further coordinated regional planning, the SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by the Sudbury to Algoma Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

Table 1: Study Team Participants for Sudbury to Algoma Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
2.	Independent Electricity System Operator
3.	Greater Sudbury Hydro Inc ("Sudbury Hydro")
4.	Hydro One Networks Inc. (Distribution)

2 REGIONAL ISSUE / TRIGGER

The NA for the Sudbury to Algoma Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Sudbury to Algoma Region belongs to Group 2. The NA for this Region was triggered on October 20, 2014 and was completed on March 20, 2015

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the Sudbury to Algoma Region over an assessment period of 2014 to 2023. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 Sudbury to Algoma Region Description and Connection Configuration

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden. The boundaries of the Sudbury to Algoma Region are shown below in Figure 1.

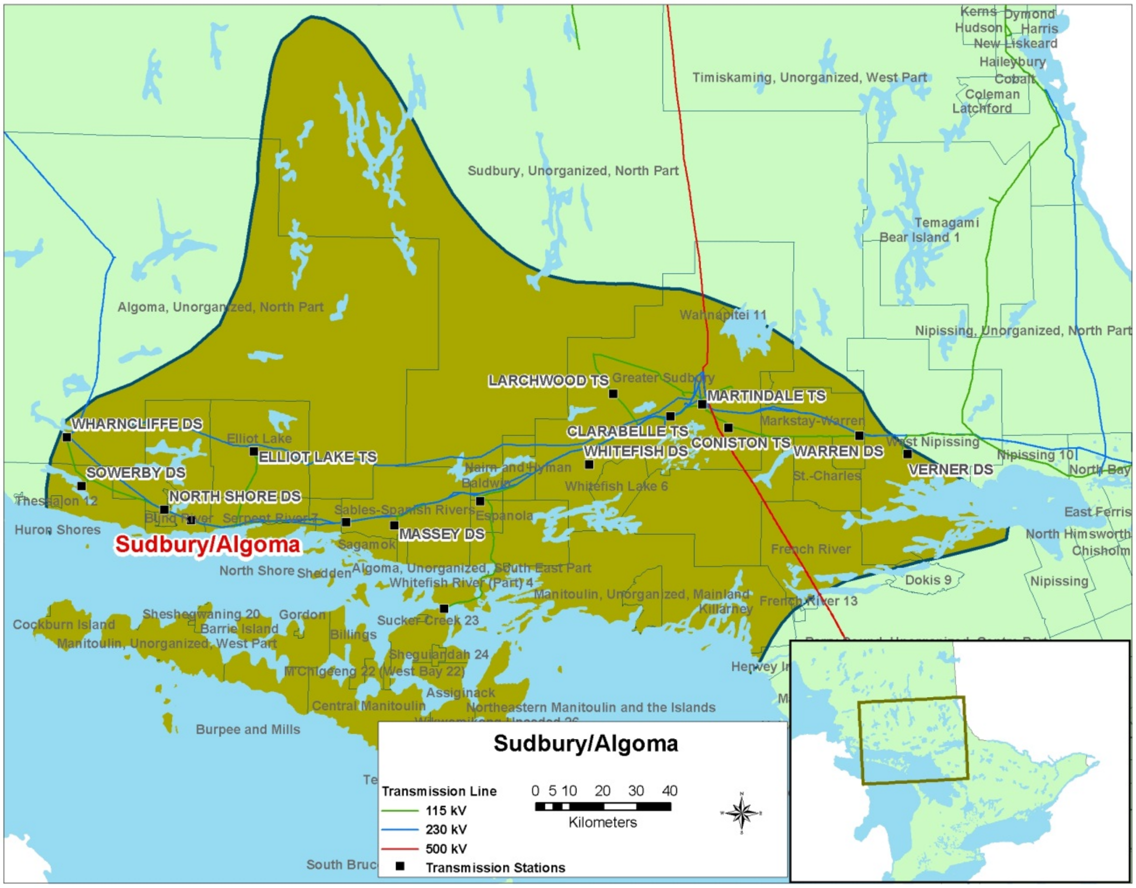

Figure 1: Sudbury to Algoma Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied by autotransformers at Hanmer TS, Algoma TS and Martindale TS. This area is further reinforced through the 500kV circuits (P502X and X504/503E) connecting Hanmer TS (Sudbury) to both Porcupine TS (Timmins) and Essa TS (Barrie). It is also connected to Northwest Ontario through Mississagi TS. Table 2 below lists the major transmission circuits and Hydro One stations in the subject region.

This region has the following two local distribution companies (LDC):

- Greater Sudbury Hydro Inc.
- Hydro One Networks Inc. (Distribution)

Espanola Regional Hydro Distribution is a third LDC in this region embedded into the Hydro One Disribution system. Although invited to participate in the Study Team, the interests of this LDC was communicated through Hydro One Distribution.

Tranmission connected loads in the Sudbury to Algoma region form a large percentage (approximately 50%) of the overall demand. Although these customers are not explicitly participating in the regional planning process, Hydro One will consider their impact in the NA of this region.

Table 2: Transmission Lines and Stations in Sudbury to Algoma Region

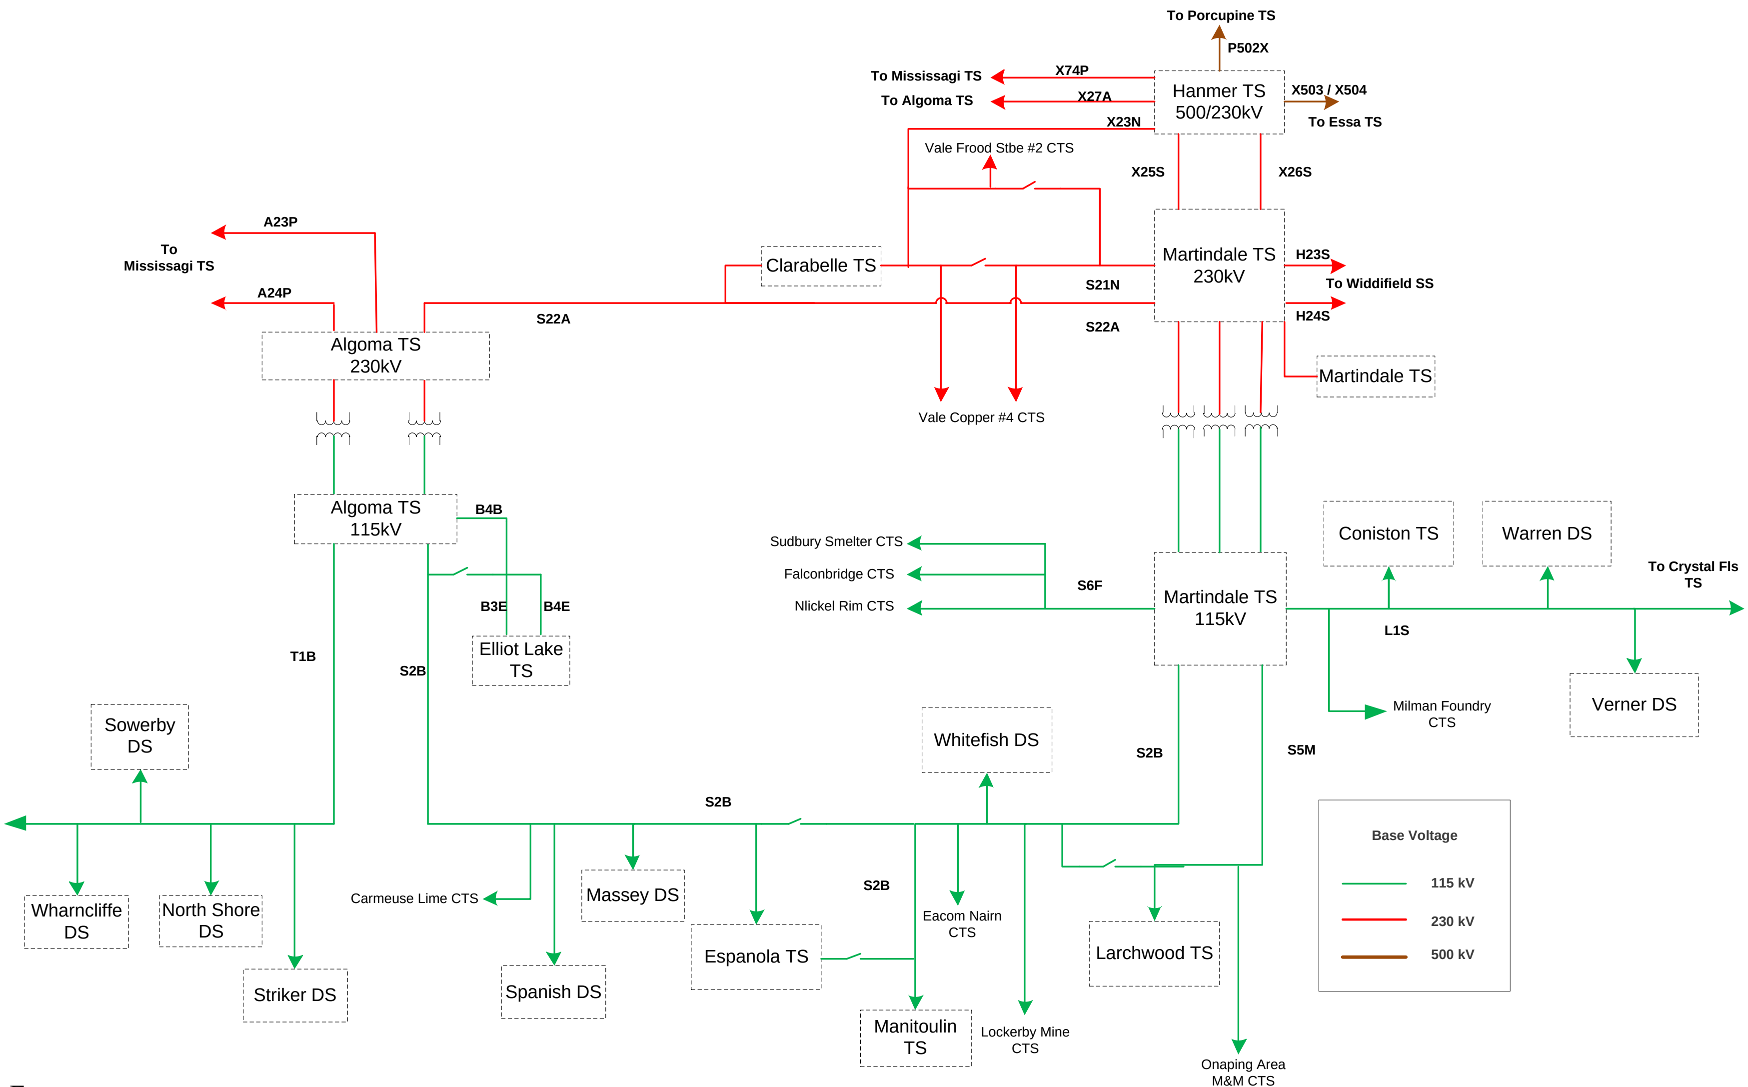

Figure 2: Single Line Diagram – Sudbury to Algoma Region

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
    i. Historical 2013 regional coincident peak load and station non-coincident peak load
    ii. List of existing reliability and operational issues
    iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2011-2013) net load and gross load forecast (2014-2023)
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Load Forecast

As per the data provided by the study team, the gross load in region is expected to grow at an average rate of approximately 0.3% annually from 2014-2023.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. The net load is expected to decrease at an average rate of approximately 0.2% annually from 2014-2023.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is winter peaking so this assessment is based on winter peak loads.
2. Forecast loads are provided by the Region's LDCs (Greater Sudbury Hydro Inc, Hydro One Distribution).
3. Load data was provided by industrial customers in the region. Where data was not provided, the load was assumed to be consistent with historical loads.
4. The LDC's load forecast is translated into load growth rates and is applied onto the 2013 winter peak load as a reference point.
5. The 2013 winter peak loads are adjusted for extreme weather conditions according to Hydro One's methodology.

6. Accounting for (2), (3), (4) above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG is analyzed to determine if needs can be deferred. A gross and net non-coincident peak load forecast was used to perform the analysis for Section 6.1.3 of this report.
   A gross and net region-coincident peak load forecast was used to perform the analysis for sections 6.1.1 and 6.1.2.
   Review impact of any on-going and/or planned development projects in the Region during the study period.
7. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer or winter 10-Day Limited Time Rating (LTR), as appropriate.
9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their winter long-term emergency (LTE) ratings. Thermal limits for transformers are acceptable using winter loading with winter 10-day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Sudbury to Algoma Region.

6.1 Transmission Capacity Needs

6.1.1 230/115 kV Autotransformers

The 230/115 kV autotransformers (Algoma TS, Martindale TS, Hanmer TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.1.2 Transmission Lines & Ratings

The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

The 115 kV circuits supplying the Region are adequate over the study period.

6.1.3 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station winter peak load forecast provided by the study team. All stations in the area have adequate supply capacity for the study period (2014-2023).

6.1.4 Pre-contingency voltages at Manitoulin TS 115kV

Pre-contingency voltages at Manitoulin TS 115kV bus can be below the ORTAC criteria of 113 kV. This issue has been also identified by the IESO as part of their System Impact Assessments.

6.2 System Reliability, Operation and Restoration

Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to The loss of two elements is below the load loss limit of 600MW by the end of the 10-year Study period. For the loss of one or two elements, the load interrupted by configuration does not exceed 150 MW or 250 MW. Review of the power network in the area indicates that all loads in the Sudbury-Algoma area can be restored within the 8 hour requirement.

6.2.1 Post contingency voltage declines at Martindale TS

With either X25S or X26S is out of service, the loss of the companion circuit may result in voltage declines at Martindale 230kV and 115kV buses below acceptable ORTAC limits. This issue has been presented in the IESO System Impact Assessment Victoria

Advanced Exploration Project (CAA 2013-512). In this assessment, voltage declines at the Martindale 230kV and 115 kV buses were found to be greater than the 10% limit.

6.2.2 Post Contingency Thermal Overload of Martindale Autotransformers

Under peak load conditions, the loss of two Martindale 230/115kV transformers may result in the overload of the third Martindale transformer. This issue has been presented in the IESO System Impact Assessment Process Gas (CAA 2012-488).

The double element contingency presented here occurs on the premise that all 115kV area loads would be supplied from one remaining autotransformer at Martindale TS. The worst case would be with Martindale T23 transformer remaining as it has the lowest STE (Short Term Emergency) rating.

Replacement of the autotransformers is listed in Hydro Ones 5yr sustainment business plan. T21/T23 autotransformers at Martindale TS may result in higher emergency ratings. In addition, loads connected to S2B (from Martindale) can also be transferred to S2B from Algoma, reducing Martindale 115kV load.

The above issues (6.2.1, 6.2.2) will be further assessed as part of bulk system planning outside of the regional planning process.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables. During the study period:

- Replace T21/T23 230/115kV autotransformers at Martindale TS
- Build a new 230/44kV station at Hanmer TS to replace Coniston TS (115/22kV). As part of this project, Coniston loads will be converted from 22kV to 44kV
- Replace 115/44kV power transformers at Espanola TS (T1/T2) and Larchwood TS (T2)

7 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, the study team recommends that no further coordinated regional planning is required. It is further recommended that following needs identified be best addressed by wires options thru local planning led by Hydro One:

Manitoulin TS - Pre-contingency voltages

- Low pre-contingency voltages at 115kV Manitoulin TS.

8 NEXT STEPS

Following the Needs Assessment process, the next regional planning steps, based on the evaluation conducted by this assessment is for Hydro One Transmission and impacted LDCs to carry out the local planning studies identified in Section 7

Chatham-Kent/Lambton/Sarnia

Regional Infrastructure Plan

August 21, 2017

Prepared by Hydro One Networks Inc. (Lead Transmitter)

With support from:

Companies
Independent Electricity System Operator (IESO)
Bluewater Power Distribution Corporation
Entegrus Inc.
Hydro One Networks Inc. (Distribution)

Disclaimer

This Regional Infrastructure Plan ("RIP") was prepared for the purpose of developing an electricity infrastructure plan to address needs identified in the Chatham-Kent/Lambton-Sarnia Region. The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the members in the region.

Participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

EXECUTIVE SUMMARY

This Regional Infrastructure Plan ("RIP") was prepared by Hydro One, with input from the Region's Local Distribution Companies ("LDCs") and the IESO in accordance with the Ontario Transmission System Code ("TSC") and Distribution System Code ("DSC") requirements. It summarizes investments in transmission facilities, distribution facilities, or both, recommended to meet the electricity infrastructure needs within the Chatham-Kent/Lambton/Sarnia Region.

The regional planning process for the Chatham-Kent/Lambton/Sarnia Region was initiated with a Needs Assessment in April 2016, which identified loading at Kent TS would exceed their transformer 10-day Limited Time Rating ("LTR") in 2016 based on the net load forecast. The Needs Assessment Study Team recommended Hydro One and relevant LDCs to develop a Local Plan to address this issue ("Kent TS T3 Capacity Limitation"). This Local Plan was completed in June 2017, and concluded that there is existing distribution transfer capability to ensure that the transformer T3 would not exceed its LTR.

The major sustainment projects planned for the region over the near and medium-term are given as below:

- Refurbishment of existing Wanstead TS is currently underway and is scheduled to be completed in 2018;
- Chatham SS component replacement, including a capacitor and the associated breaker, is planned to be completed by 2023;
- St. Andrews TS T3, T4 & switchyard refurbishment, planned to be completed by 2023;
- Sarnia Scott TS T5 & Component Replacement, which includes autotransformer T5, breaker, and other components, planned to be completed by 2024.

In accordance with the regional planning process as mandated by the TSC and DSC, the next planning cycle will be started no later than 2020. However, should there be a need that emerges due to a change in load forecast or any other reason, the regional planning cycle may commence earlier to address the need.

List of Figures

List of Tables

1. INTRODUCTION

This Regional Infrastructure Plan ("RIP") summarizes all the regional planning activities undertaken in the Chatham-Kent/Lambton/Sarnia Region. It was prepared by Hydro One Networks Inc. ("Hydro One") as the lead transmitter in the region, and is supported by the representatives from Bluewater Power Distribution Corporation, Entegrus Inc., Hydro One Networks Inc. (Distribution), and the Independent Electricity System Operator ("IESO"). This RIP is the final phase of the regional planning process for the region in accordance with the Ontario Transmission System Code ("TSC") and Distribution System Code ("DSC") requirements.

1.1 Background and Scope

In accordance with the TSC and DSC amendments in August 2013, the regional planning process for the Chatham-Kent/Lambton/Sarnia Region began with Needs Assessment in April 2016 and was completed in June 2016.

Based on the findings, the Needs Assessment Study Team agreed that Scoping Assessment was not required for this region at the time. The only need identified, thermal overloading of transformer T3 at Kent TS, was to be addressed between Hydro One (transmitter) and relevant LDCs through Local Planning process which was completed in June 2017.

Being the final phase of the regional planning process, the scope of this RIP includes a comprehensive summary of the needs and relevant wire plans to address near and medium-term needs (2015-2025) identified in previous planning phases.

2. REGIONAL DESCRIPTION

The Chatham-Kent/Lambton/Sarnia Region, as shown in Figure 2-1, includes the municipalities of Lambton Shores and Chatham-Kent, as well as the townships of Petrolia, Plympton-Wyoming, Brooke-Alvinston, Dawn-Euphemia, Enniskillen, St. Clair, Warwick, and Villages of Oil Springs and Point Edward. The area is bordered by the London area to the east and Windsor-Essex to the southwest. The region's summer coincident peak load was about 710 MW in 2016.

Figure 2-1 Map of Chatham-Kent/Lambton/Sarnia Region

Electricity supply for the region is provided through a network of 230 kV and 115 kV transmission lines. The bulk of the electrical supply is transmitted through 230 kV circuits (N21W/N22W, L24L/L26L, and W44LC/W45LS) towards Buchanan TS. This region also contains a number of interconnections with neighboring Michigan State (B3N, L4D, and L51D). Figure 2-2 shows Hydro One transmission and transmission-connected customers' assets in the Chatham-Kent/Lambton/Sarnia Region.

Large gas-fired generators in the region include: Greenfield Energy Centre CGS, TransAlta Sarnia CGS, St. Clair Power CGS, and Greenfield South Power Corporation (GSPC). Lists of transmission lines, stations, and distributors (LDCs) in the region are provided in Appendix A, B, and C, respectively.

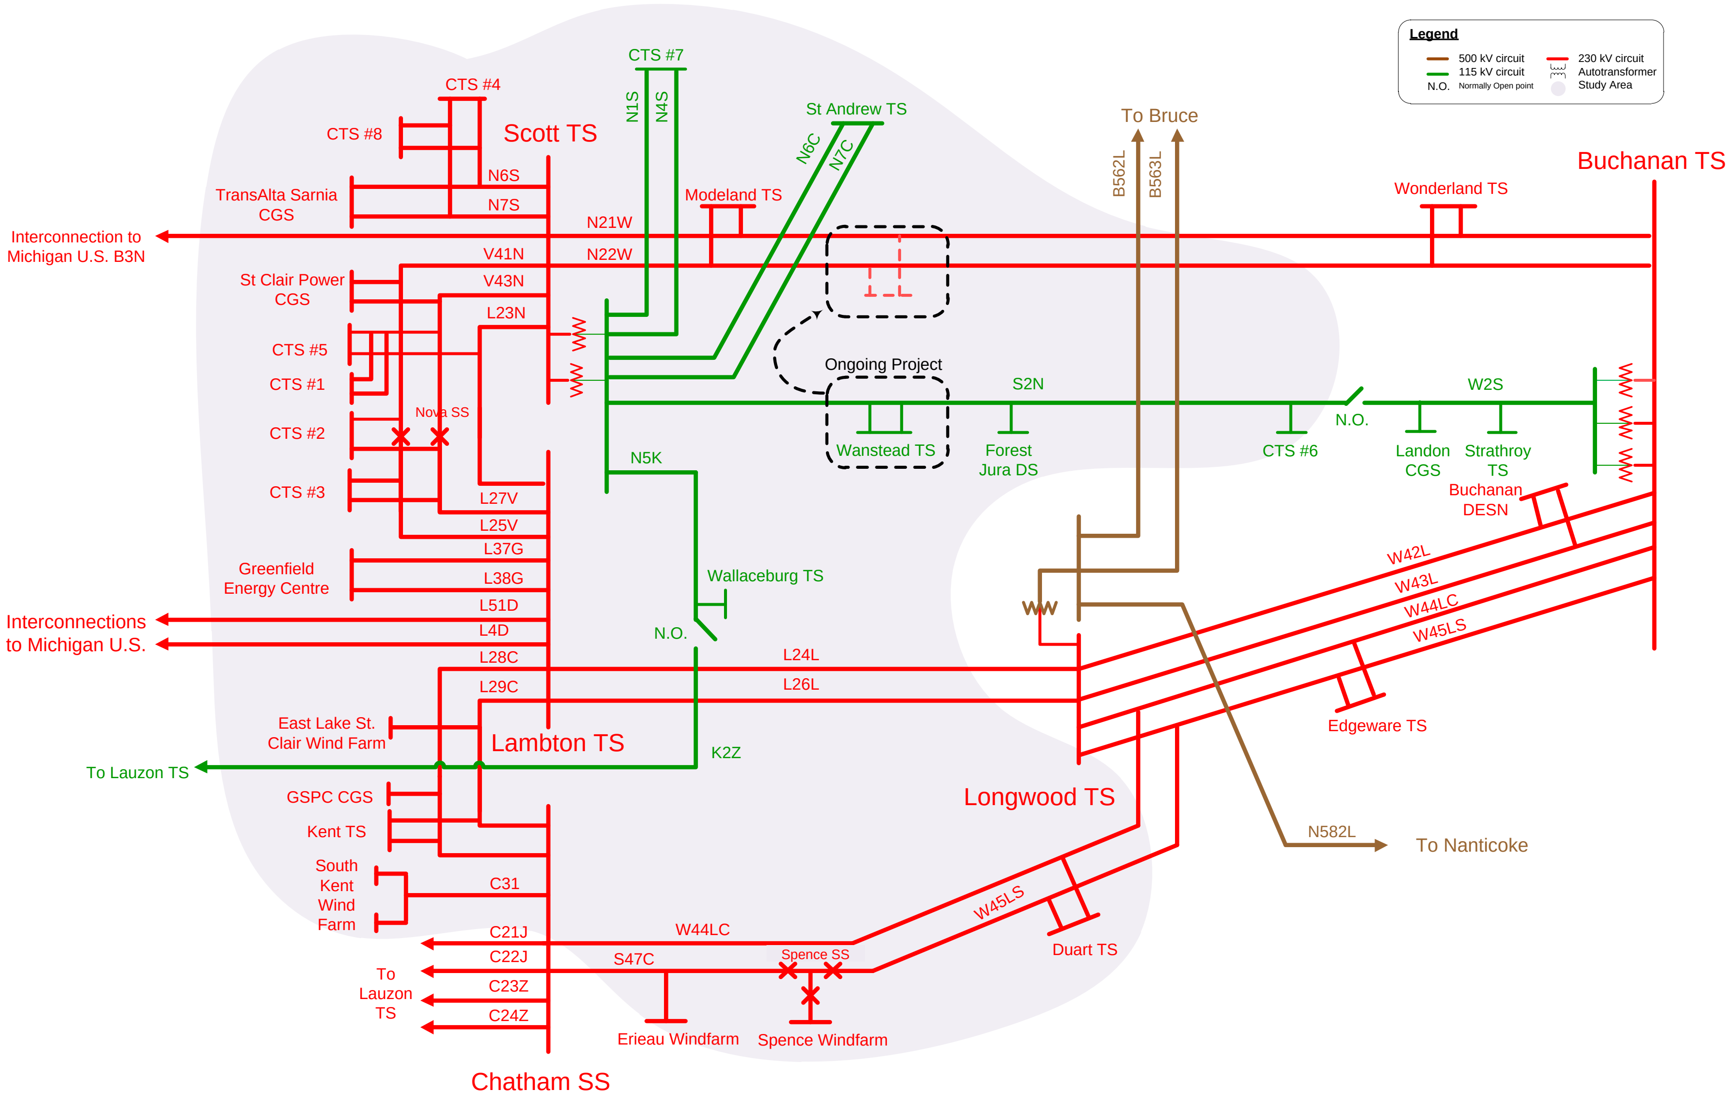

Figure 2-2 Single Line Diagram of Chatham-Kent/Lambton/Sarnia Region

3. NEEDS ASSESSMENT RESULTS

3.1 Load Forecast

During the Needs Assessment phase, LDCs in the region provided gross load forecasts for Hydro One's step-down transformer stations and assumed 2015 historical extreme weather-corrected summer peak loads as reference points. As for transmission connected industrial customers, 2014 historical load levels were assumed throughout the study period.

Based on data provided by the Study Team, the summer gross coincident load in the region is expected to grow at an average rate of approximately 1.3% annually over the next 10 year period. Factoring in the contributions of conservation and demand management and distributed generation, the summer net coincident load in the region is expected to grow at an average rate of approximately 0.2% annually.

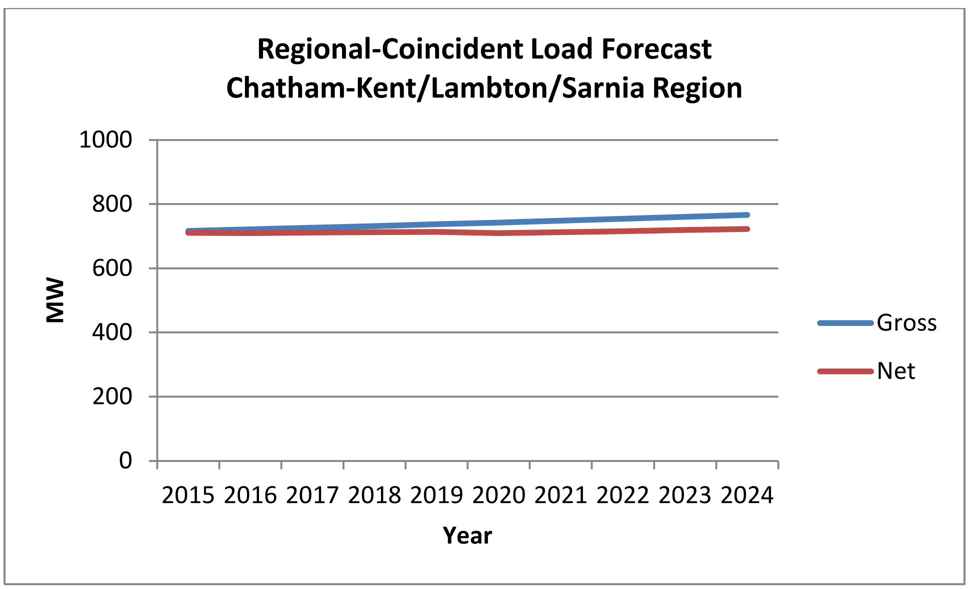

Figure 3-1 Regional load forecast during Needs Assessment

Further load forecast details are provided in Appendix D.

3.2 Major Transmission Projects Completed or Underway

Over the last 10 years, a number of major transmission projects, shown below, have been completed by Hydro One aimed to maintain or improve the reliability and adequacy of supply in the Chatham-Kent/Lambton/Sarnia Region:

- Lambton to Longwood 230kV L24L/L26L Circuit Reconductoring
- New Transformer Station Duart TS

In addition, as part of Hydro One's transmission rates application (EB-2016-0160), existing Wanstead TS has been identified as reaching end-of-life. Effort is underway to convert Wanstead TS from 115 kV to 230 kV and connecting to 230 kV circuits N21W/N22W. The target in-service date is Q4 2018.

3.3 Regional Needs

The results from the Needs Assessment for the region are summarized below:

Table 3-1 Regional Needs

No.	Needs	Description
1	Kent TS Capacity	Loading at Kent TS is expected to exceed the transformer 10-day limited time rating (LTR) in 2016 based on the net load forecast.
2	End-of-Life equipment at St. Andrews TS, Scott TS, and Chatham SS	During the study period, plans to replace end of life equipment at St. Andrews TS, Scott TS, and Chatham SS[1] are identified.

4. RECOMMENDED PLANS

This section provides a consolidated summary of the regional infrastructure plans for addressing needs in the Chatham-Kent/Lambton/Sarnia Region.

4.1 Kent TS Transformation Capacity

Based on the information available at the time of Chatham-Kent/Lambton/Sarnia Region Needs Assessment, it was identified that transformer T3 at Kent TS will be overloaded for the loss of its companion transformer T4. Subsequently, local planning team consists of Hydro One and impacted LDCs had undertaken further investigations and determined there is a sufficient transfer capability on the distribution system to offload Kent TS T3. Therefore, the local planning team agreed no further action is required at this time.

[1] The need to replace end-of-life equipment at Chatham SS was identified post completion of the 2016 Needs Assessment report.

4.2 Sustainment Plans

As part of Hydro One's transmitter license requirements, Hydro One continues to ensure a reliable transmission system by carrying out maintenance programs as well as periodic replacement of equipment based on their condition. Since the conclusion of Needs Assessment, additional sustainment projects have been planned for the region in the medium-term. Below is a list of Hydro One's major transmission sustainment projects in the Chatham-Kent/Lambton/Sarnia Region that are currently planned. Note that the project scopes and timelines are currently under development and may change accordingly.

- Chatham SS Component Replacement, mainly to replace capacitor SC21 and the associated breaker and is planned to be completed by 2023.
- St. Andrews TS T3, T4 & Switchyard Refurbishment, planned to be completed by 2023. The current scope includes both transformers and a breaker replacement.
- Sarnia Scott TS T5 & Component Replacement, which includes autotransformer T5, breaker, and other components, planned to be completed by 2024.

5. CONCLUSION AND NEXT STEPS

This Regional Infrastructure Plan (RIP) report summarizes the regional planning activities for the Chatham-Kent/Lambton/Sarnia Region and concludes the first regional planning cycle for the region.

As mandated by the OEB, next planning cycle will begin no later than 2020. Should there be a need that emerges due to change in load forecast or any other reason, the regional planning cycle will be started earlier to address the need.

Disclaimer

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs (2016-2025) identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE PLANNED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GREATER BRUCE-HURON REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Entegrus Power Lines Inc.
- Erie Thames Powerlines Corporation
- Festival Hydro Inc.
- Goderich Hydro - West Coast Huron Energy Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Wellington North Power Inc.
- Westario Power Inc.

This RIP is the final phase of the regional planning process for the Greater Bruce-Huron Region and provides a consolidated summary of needs and recommended plans for the Greater Bruce-Huron Region for the near-term (up to 5 years) and mid-term (5 to 10 years). No long term needs (10 to 20 years) have been identified.

Investments planned for the Greater Bruce-Huron Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the table below.

No.	Project	In-Service Date	Cost
1	Improve L7S Customer Delivery Point Performance	Staged Plan 2017-2023	$154k - TBD
2	Accommodation for Connection Capacity Requests near Kincardine– Hydro One Network Inc. Distribution	TBD (customer dependent)	TBD

In accordance with the Regional Planning process, the RIP should be reviewed and/or updated at least every five years. The Region will continue to be monitored and should there be a need that emerges earlier due to a change in load forecast or any other reason, the next regional planning cycle will be started to address the need.

Table of Contents

List of Tables

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE GREATER BRUCE-HURON REGION.

The report was prepared by Hydro One Networks Inc. (“Hydro One”) and documents the results of the joint study carried out by Hydro One, Entegrus Power Lines Inc., Erie Thames Powerlines Corporation, Festival Hydro Inc., Hydro One Distribution, the Independent Electricity System Operator (“IESO”), Wellington North Power Inc., Goderich Hydro - West Coast Huron Energy Inc. and Westario Power Inc. in accordance with the Regional Planning process established by the Ontario Energy Board (“OEB”) in 2013.

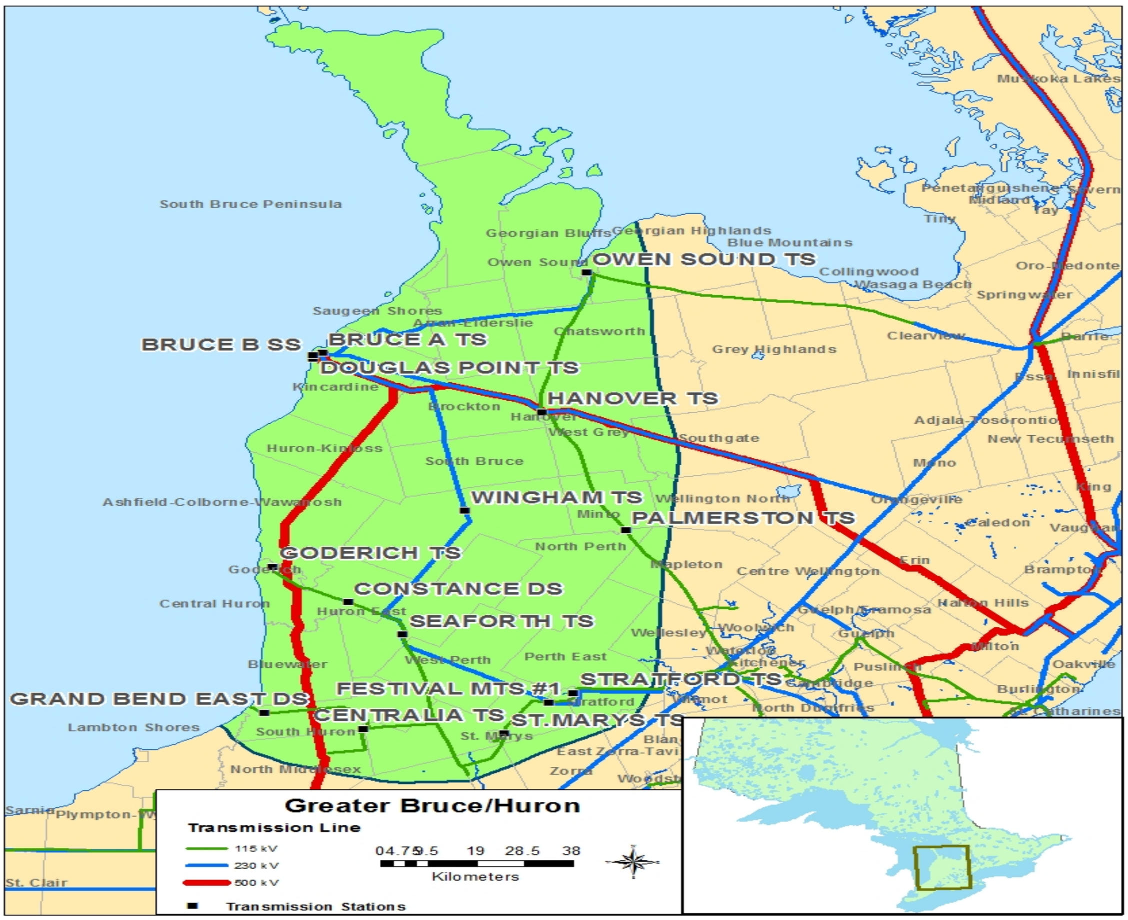

Figure 1-1 Greater Bruce-Huron Region

The Greater Bruce-Huron Region includes the counties of Bruce, Huron and Perth, as well as portions of Grey, Wellington, Waterloo, Oxford and Middlesex counties. Electrical supply to the Region is provided from six 230 kV and twelve 115 kV step-down transformer stations. The boundaries of the Region are highlighted in Figure 1-1 above.

1.1 Objective and Scope

This RIP report examines the needs in the Greater Bruce-Huron Region. Its objectives are:

- To develop a wires plan to address needs identified in previous planning phases for which a wires only alternative was recommended by the Working Group
- To identify new supply needs that may have emerged since previous planning phases (e.g. Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan)
- To provide the status of wires planning currently underway or completed for specific needs
- To identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region

The RIP reviewed factors such as the load forecast, major high voltage sustainment work, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management (CDM), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of all the needs and relevant plans to address near and mid-term needs (2016-2025) identified in previous planning phases (Needs Assessment or Local Plan)
- Identification of any new needs over the 2016-2025 period
- Develop a plan to address any longer term needs identified by the Working Group

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the region
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies needs
- Section 7 summarizes the Regional Plan to address the needs
- Section 8 provides the conclusion and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013, through amendments to the Transmission System Code ("TSC") and the Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ('SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource options (e.g. CDM, generation and Distributed Energy Resources ("DER")) at a higher or more macro level but sufficient to permit a comparison of options. If the IRRP process identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the

---

[1] Also referred to a Needs Screening

specific wires alternatives and recommend the preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution was determined to be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timeliness provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the Greater Bruce-Huron region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA and LP phases of regional planning.
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

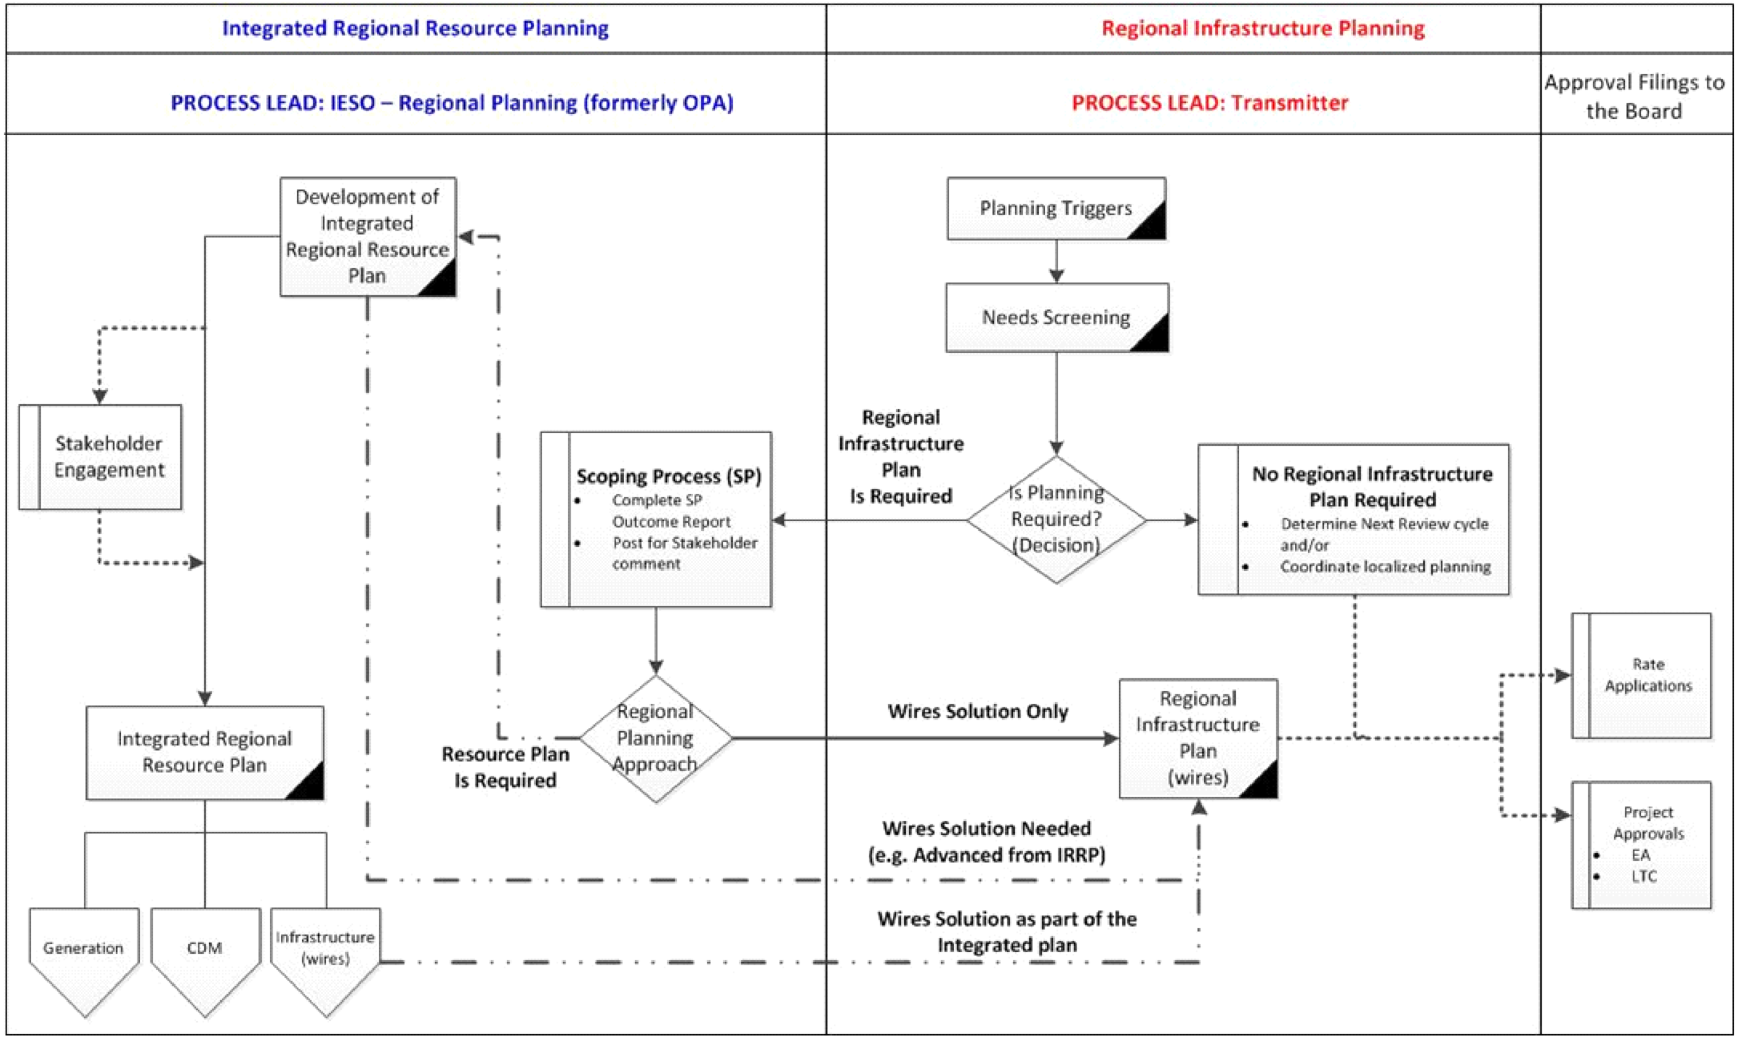

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP phase is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Gross and net peak demand forecast at the transformer station level. This includes the effect of any distributed generation and/or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

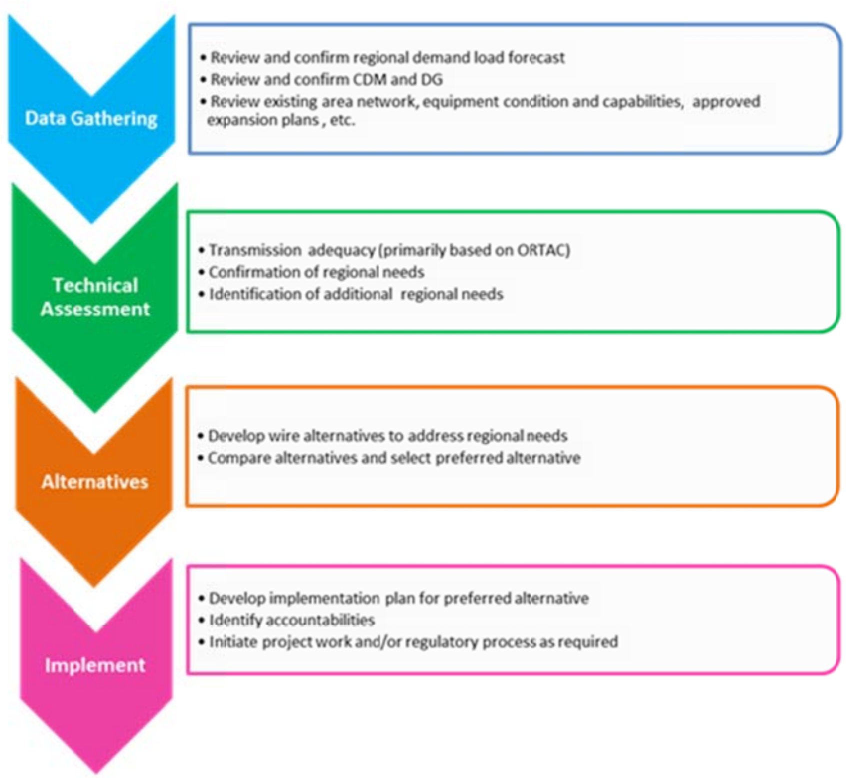

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GREATER BRUCE-HURON REGION COMPRISES OF THE COUNTIES OF BRUCE, HURON, AND PERTH, AS WELL AS PORTIONS OF GREY, WELLINGTON, WATERLOO, OXFORD, AND MIDDLESEX COUNTIES AS SHOWN IN FIGURE 3-1.

Electricity supply for the Region is provided through a network of 230 kV and 115 kV transmission lines supplied mainly by generation from the Bruce Nuclear Generating Station and local renewable generation facilities in the Region. The majority of the electrical supply in the region is transmitted through 230 kV circuits (B4V, B5V, B22D, B23D, B27S and B28S) radiating out from Bruce A TS. These circuits connect the Region to the adjacent South Georgian Bay/Muskoka Region and the adjacent Kitchener-Waterloo-Cambridge-Guelph (KWCG) Region.

Within the Region, electricity is delivered to the end users of LDCs and directly-connected industrial customers by eleven Hydro One step-down transformation stations, as well as seven customer-owned transformer or distribution stations supplied directly from the transmission system. Appendix A lists all step-down transformer stations in the Region. Appendix B lists all transmission circuits and Appendix C lists LDCs in the Region. The Single Line Diagram for the Greater Bruce-Huron Region transmission system facilities is shown below in Figure 3-2.

Figure 3-1 Geographical Area of the Greater Bruce-Huron Region with Electrical Layout

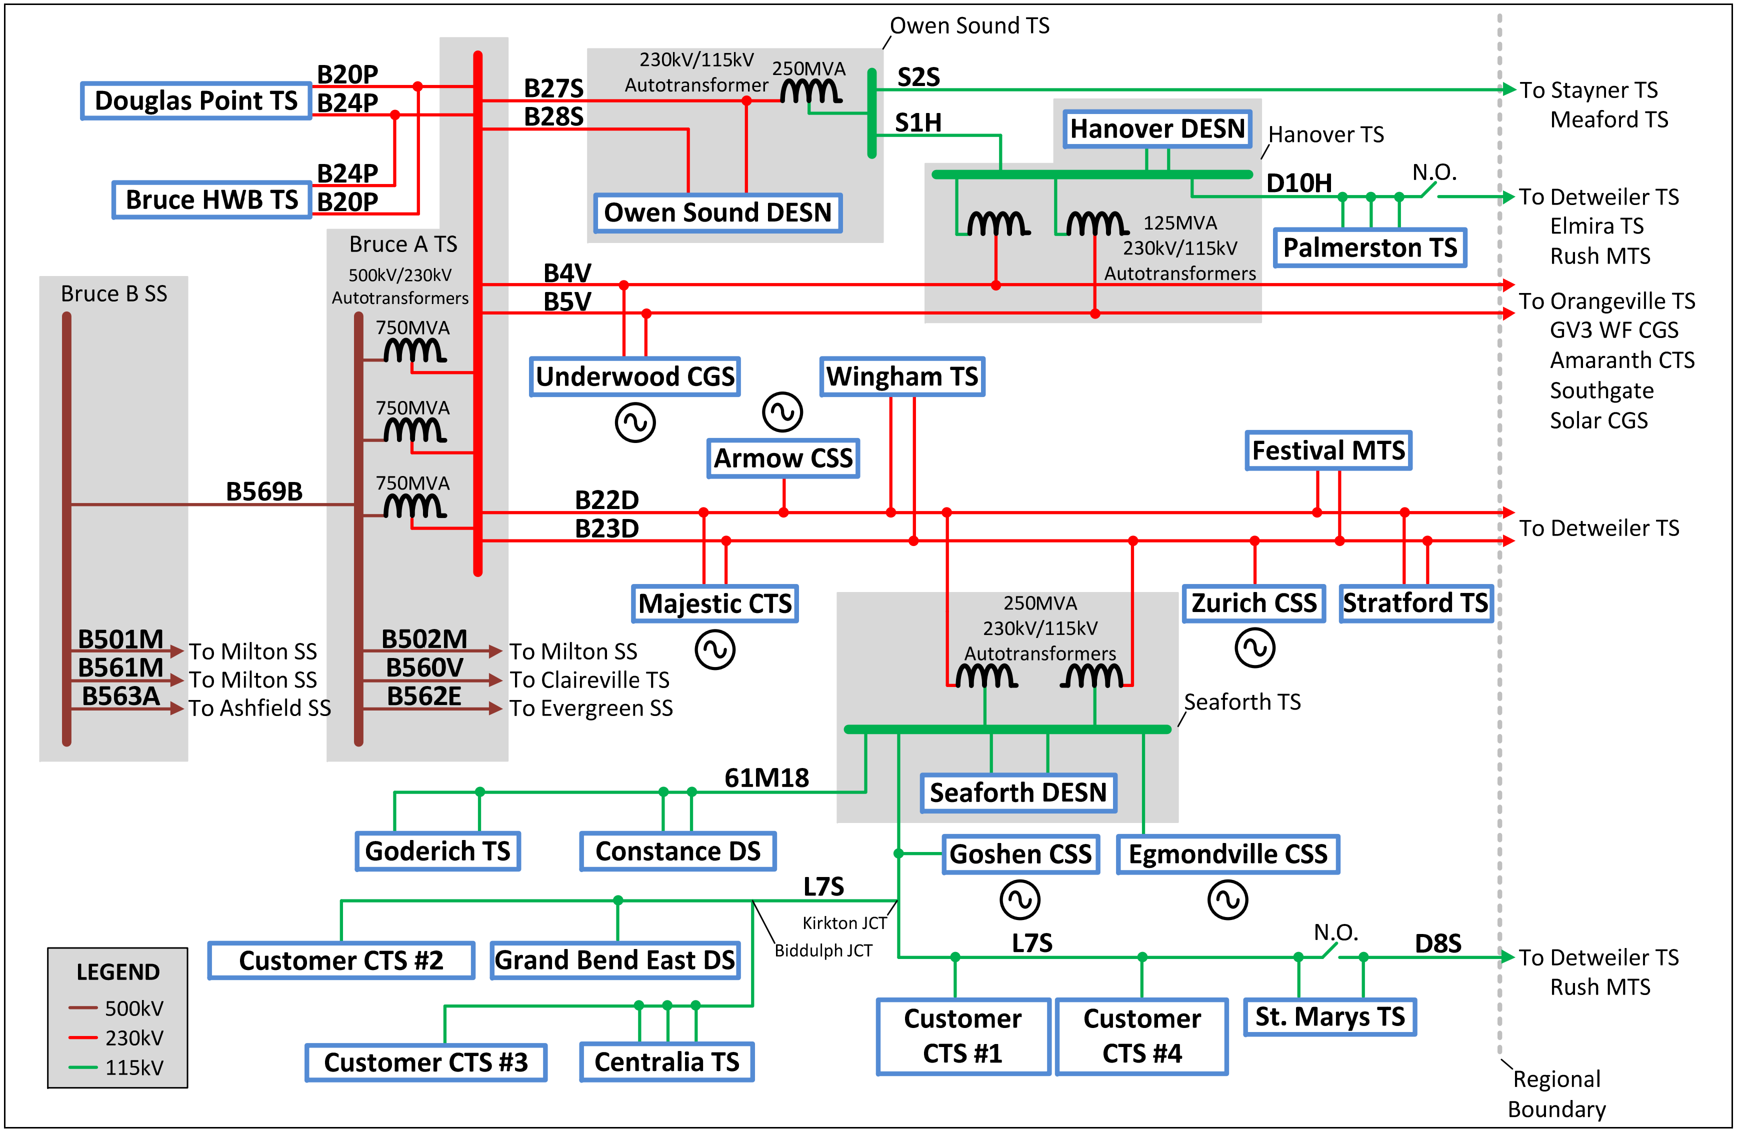

Figure 3-2 Greater Bruce-Huron Region Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GREATER BRUCE-HURON REGION.

In addition to Hydro One's ongoing transmission station and line sustainment programs, specific projects were identified as a result of joint planning studies undertaken by Hydro One, IESO and the LDCs; or initiated to meet the needs of the LDCs; and/or to meet Provincial Government policies. A brief listing of the completed projects is given below.

For reactive and voltage support needs:

- a 230 kV shunt capacitor bank installed at Detweiler TS in 2007
- a 230 kV shunt capacitor bank installed at Orangeville TS in 2008

For bulk power system transfer needs:

- 500 kV double circuit line from the Bruce Nuclear Complex to Milton SS in 2011
- 230 kV Static Var Compensator (SVC) at Detweiler TS in 2011

For major station refurbishment needs based on asset condition assessment:

- Goderich TS in 2016

For renewable generation connection needs:

- 230 kV Melancthon Grey Wind Farm onto circuits B4V/B5V in 2006/2008
- 230 kV Ripley Wind Farm onto circuits B22D/B23D in 2007
- 230 kV Underwood Wind Farm onto circuits B4V/ B5V in 2008
- 230 kV Dufferin Wind Farm into Orangeville TS in 2014
- 500 kV Jericho/Adelaide/Bornish Wind Farms into Evergreen SS in 2014
- 230 kV Grand Valley 3 Wind Farm onto circuit B4V in 2015
- 115 kV Bluewater Wind Farm into Seaforth TS in 2015
- 115 kV Goshen Wind Farm onto circuit L7S in 2015
- 500 kV K2 Wind Farm into Ashfield SS in 2015
- 230 kV Grand Bend Wind Farm onto circuit B23D in 2016
- 230 kV Armow Wind Farm onto circuit B22D in 2016
- 230 kV Southgate Solar Farm onto circuit B4V in 2016

The following projects are underway:

- Centralia TS is currently undergoing major station refurbishment work with a projected in-service of 2018.
- Palmerston TS is currently undergoing major station refurbishment work with a projected in-service of 2018.
- Bruce A TS 230 kV switchyard is currently undergoing major station refurbishment work with a projected in-servicing by 2019.
- Replacement of the Bruce Special Projection Scheme (BSPS) is currently underway with a projected in-service of 2018.
- Modification to the Bruce Reactor Switching Scheme (RSS) is currently underway with a projected in-service of 2018.

5. LOAD FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the Greater Bruce-Huron Region is forecast to increase annually between 2016 and 2025. The growth rate varies across the Region with most of the growth concentrated in the County of Bruce and more specifically in the Kincardine area. The Region's 2017 RIP load forecasts are provided in Appendix D and were prepared by the Working Group upon initiation of the RIP phase. The RIP forecasts are identical to the Needs Assessment forecast except as otherwise noted in Appendix D.

As per the load forecasts in Appendix D, the winter *gross* coincident load in the Region is expected to grow at an average rate of approximately 1.4% annually from 2016-2025 and the summer *gross* coincident load in the Region is expected to grow at an average rate of approximately 1.3% from 2016-2025.

As per the load forecasts in Appendix D, the winter *net* coincident load in the Region is expected to grow at an average rate of approximately 0.8% annually from 2016-2025 and the summer *net* coincident load in the Region is expected to grow at an average rate of approximately 0.6% from 2016-2025.

Figure 5-1 shows the Region's gross and net *winter* coincident forecasts while Figure 5.2 shows the Region's gross and net *summer* coincident forecasts. The regional-coincident (at the same time) forecast represents the total peak load of all 18 step-down transformer stations in the Region.

Based on historical load and on the coincident load forecasts, the Region's winter coincident peak load is larger than its summer coincident peak load. Based on historical load and the non-coincident load forecasts, the Region contains some stations that are summer peaking and others that are winter peaking. Equipment ratings are normally lower in the summer than winter due to ambient temperature. Based on these factors assessment for this Region was conducted for both summer and winter peak load.

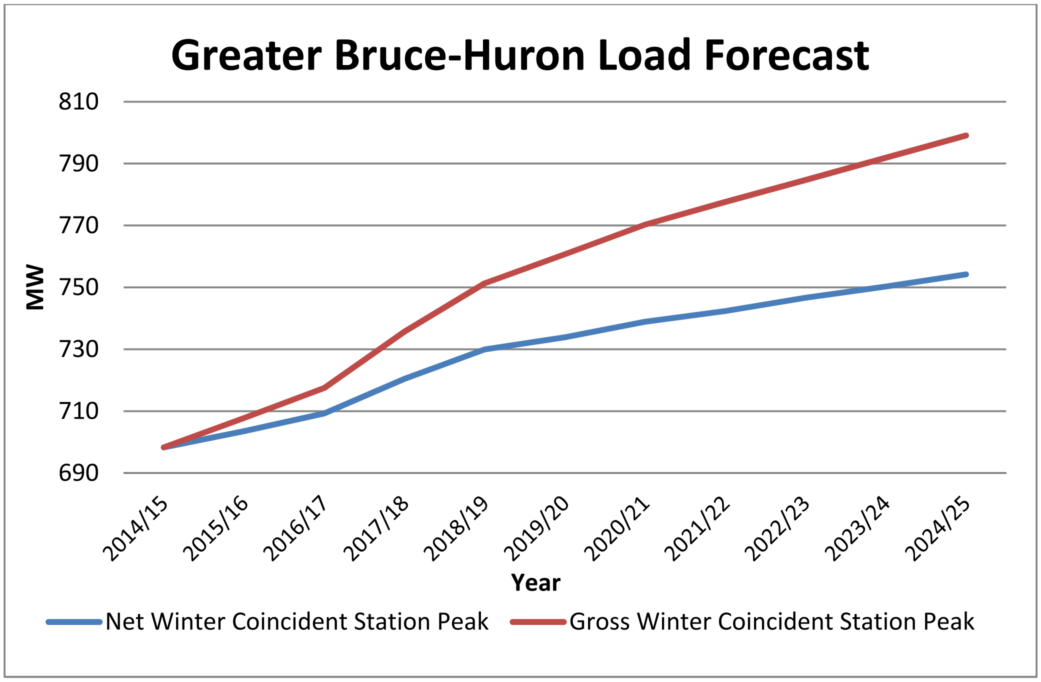

Figure 5-1 Greater Bruce-Huron Region Winter Extreme Weather Peak Forecast

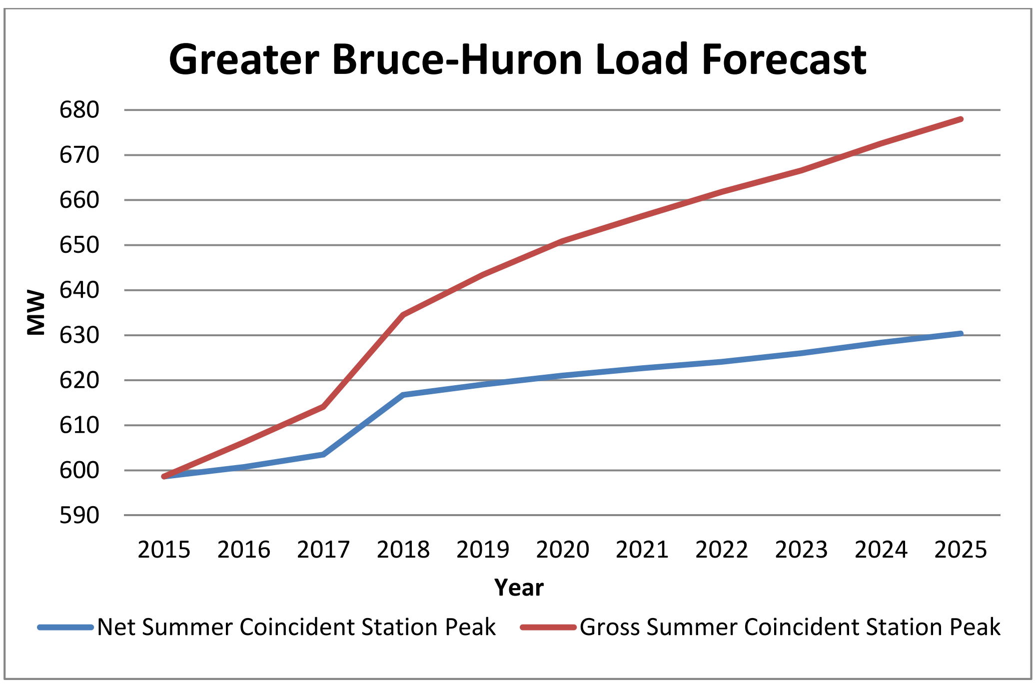

Figure 5-2 Greater Bruce-Huron Region Summer Extreme Weather Peak Forecast

5.2 Study Assumptions

The following assumptions are made in this report.

1) The study period for the RIP assessments is 2016-2025.

2) All planned facilities listed in Section 4 are assumed to be in-service.

3) The Region contains some stations that are summer peaking and others that are winter peaking. The assessment is therefore based on both summer and winter peak loads.

4) Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity by assuming a 90% lagging power factor for stations without low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer and winter 10-Day Limited Time Rating (LTR), as appropriate.

5) Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2016-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND STEP-DOWN TRANFORMATION STATION FACILITIES SUPPLYING THE GREATER BRUCE-HURON REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM.

Within the current regional planning cycle, five regional assessments have been conducted for the Greater Bruce-Huron Region. The findings of these studies are input to the RIP. The studies are:

1) Needs Assessment Report - Greater Bruce-Huron Region, May 2016
2) Local Planning Report - Low Power Factor at Wingham TS, October 2016
3) Local Planning Report - Circuit L7S Thermal Overload, November 2016
4) Local Planning Report - Low Power Factor at Bruce HWP B TS, May 2017
5) Customer Delivery Point Performance Review, 2016-2017

This RIP reviewed the loading on transmission lines and stations in the Greater Bruce-Huron Region based on the RIP load forecast. Sections 6.1-6.6 presents the results of this review and Table 6-1 lists the Region's needs identified in both the Needs Assessment and the RIP phases.

In addition, this RIP reviewed an updated list of Hydro One transmission lines and station major sustainment work over the next several years to determine if there are opportunities to consolidate with any emerging development needs within the Region. Section 7.5 presents the results of this review.

</table>

6.1 230 kV Transmission Facilities

Half of the 230 kV transmission circuits in the Greater Bruce-Huron Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of Ontario's transmission system and are also part of the transmission path from generation in Southwestern Ontario to the load centers in the KWCG, Georgian Bay and GTA areas. These circuits also serve local area stations within the Region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (refer to Figure 3-2):

1) Bruce A TS to Orangeville TS 230kV transmission circuits B4V/B5V – supplies Hanover TS
2) Bruce A TS to Detweiler TS 230kV transmission circuits B22D/ B23D – supplies Wingham TS, Seaforth TS, Festival MTS #1, and Stratford TS
3) Bruce A TS to Owen Sound TS 230kV transmission circuits B27S/B28S – supplies Owen Sound TS
4) Bruce A TS to Douglas Point TS 230kV transmission circuits B20P/B24P – supplies Douglas Point TS and Bruce HWP B TS

The RIP review shows that based on current forecast station loadings and bulk transfers, all 230 kV circuits are expected to be adequate over the study period.

6.2 500/230 kV and 230/115 kV Transformation Facilities

Bulk power supply to the Greater Bruce-Huron Region is provided by Hydro One's 500 kV to 230 kV and 230 kV to 115 kV autotransformers. The number and location of these autotransformers are as follows:

1) Three (3) 500/230kV autotransformers at Bruce A TS
2) Two (2) 230/115kV autotransformers at Seaforth TS
3) Two (2) 230/115kV autotransformers at Hanover TS

The RIP review shows that based on current forecast station loadings and bulk transfers, the autotransformation supply capacity is adequate over the study period.

6.3 Supply Capacity of the 115 kV Network

The Greater Bruce-Huron Region contains four (4) single circuit 115 kV lines. This 115 kV network serves local area load. These circuits are as follows (see Figure 3-2):

1) Hanover TS to Detweiler TS 115 kV transmission circuit D10H with Normally Open (N/O) point at Palmerston TS – supplies Palmerston TS & Elmira TS
2) Seaforth TS to Goderich TS 115 kV transmission circuit 61M18 – supplies Constance DS and Goderich TS
3) Seaforth TS to St. Marys TS 115 kV transmission circuit L7S – supplies Grand bend East DS, Lake Huron WTP CTS, Centralia TS, McGillivray R&BP CTS, Enbridge Bryanston CTS and St. Marys Cement CTS
4) Hanover TS to Owen Sound TS 115 kV transmission circuit S1H

The RIP review shows that based on current forecast station loadings, the supply capacity of the 115 kV network is adequate over the study period, except circuit L7S. Circuit L7S will exceed its thermal rating in 2019 based on gross load forecast, and in 2025 based on net load forecast.

6.4 Step-down Transformer Stations

There are 18 step-down transformer stations within the Greater Bruce-Huron Region. Fourteen supply electricity to LDCs and four are transmission-connected industrial customer stations. These stations are listed in Appendix C. Of the 18 stations, 3 of them are owned and operated by LDCs.

As part of both the Needs Assessment as well as this RIP, step-down transformation station capacity was reviewed. Since the May 2016 Needs Assessment, the load forecasts at Seaforth TS, Stratford TS and Douglas Point TS have been modified; refer to Appendix E for the analysis of these modifications. The analysis showed that the load forecasts at Seaforth TS and Stratford TS can still be accommodated. However, the load forecast modification at Douglas Point TS will result in its transformation capacity limit being exceeded towards the end of the study period, winter 2023/2024. This is due to a 15 MW request for capacity made since the May 2016 Needs Assessment.

Furthermore, since updating the RIP forecast there has been additional connection requests for 2.2 MW, 0.5 MW and 20 MW of capacity by 2019/2020 at Douglas Point TS. The 2.2 MW and 0.5 MW requests can be accommodated within the station’s transformation capacity limits; however the 20 MW request would result in Douglas Point TS exceeding its transformation capacity within the near term (2019/2020) and cannot be fully accommodated at this time. Therefore additional step-down transformation capacity at/near Douglas Point TS is needed.

Based on the requirements of the customer requesting the 20 MW of connection capacity, three “need” scenarios have been developed:

Scenario 1 – If the customer requires all 20 MW of capacity immediately, the need for additional step-down transformation capacity is required in 2019/2020. Hydro One Transmission will work with Hydro One Distribution and the customer to develop a plan to meet the increased capacity requirement. All costs for the additional capacity will be allocated to the benefitting customer(s) as per the Transmission System Code.

Scenario 2 – If the customer accepts an offering to connect a portion of its load, the need for additional step-down transformation capacity is required in 2021 due to the inherent "organic" growth of load. In order to meet the need timeline, an expedited coordinated regional planning process will be undertaken by the IESO, Hydro One Transmission and Hydro One Distribution. Cost allocation for additional investment will depend on the solution to address the need.

Scenario 3 – If the customer elects not to proceed with its connection request, the need for additional step-down transformation capacity is require by 2023/2024. CDM would help to defer the need and therefore it is recommended to monitor load growth and re-evaluate the need in the next regional planning cycle.

6.5 Other Items Identified During Regional Planning

6.5.1 Customer Delivery Point Performance

The Needs Assessment section 6.2.5 identified that a performance review of several 115 kV customer delivery points be undertaken. A summary of the review is provided in Appendix F.

6.5.2 Low Power Factor Concerns

The Needs Assessment sections 6.2.3 identified two stations which historically have low power factor: Wingham TS and Bruce HWB TS.

6.6 Long-Term Regional Needs

A long-term, beyond 10 year, analysis was not deemed necessary by the Working Group for the Region at this time and therefore no long-term studies have been undertaken. If new long-term needs were to arise, there is sufficient time to assess them in the next planning cycle which can also be started earlier to make timely investment decisions.

7. REGIONAL PLANS

THIS SECTION SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THE NEEDS LISTED IN TABLE 6-1.

7.1 Transmission Circuit Capacity

7.1.1 Circuit L7S

L7S is a single 115 kV circuit transmission line operated radial from Seaforth TS to St. Marys TS. As per section 6.1.3 of the Needs Assessment, the circuit will reach its Load Meeting Capability (“LMC”) in 2019 based on the gross load forecast and 2025 based on the net load forecast.

Recommended Plan and Current Status

To address the transmission circuit capacity needs for L7S, the Local Planning working group created a Development Plan which recommended monitoring load growth at stations supplied from circuit L7S. The Development Plan is detailed in the Local Planning report [3]. The Development Plan specified that when loading on L7S is expected to exceed its limits within a 3 year period, Hydro One Transmission will increase the thermal rating of the limiting spans of circuit L7S. The cost to increase the rating is currently estimated to be approximately $550 k. Strengthening L7S will be sufficient for supplying load connected to L7S load for the study period. Loading beyond the study period’s forecast may then require additional voltage support. Capacity cost allocation will be as per the Transmission System Code.

<u>Current Status of the Loading on Circuit L7S</u>

The past winter (2016/2017) loading on circuit L7S was reviewed in accordance with the Development Plan. Winter peak coincident loading on the circuit was approximately 65% of the circuit capacity and did not trigger the need to increase the rating. Monitoring will continue after each peak load season, winter and summer.

7.2 Power Factor Review

7.2.1 Wingham TS

Power factor at Wingham TS is often low and does not meet IESO Market Rule requirements. As per section 6.2.3 of the Needs Assessment, the low power factor at Wingham TS is to be managed by the transmitter and affected LDCs.

Recommended Plan and Current Status

The power factor review conducted by the Local Planning working group, showed that the power factor of the load itself remains within Market Rule requirements. Further investigation revealed that the low power factor is due to the connected Distributed Generation (DG). The investigation is detailed in the Local Planning report [2]. The Local Plan recommends no mitigation is required at this time and to seek IESO's direction on power factor requirements with respect to DG.

<u>Current Status of Power Factor with Respect to Distributed Generation</u>

At this time, IESO does not recommend a Market Rule power factor amendment as the measured power factor is due to the connected DG and asks that a case by case review be conducted when the power factor consistently does not meet the Market Rule requirement.

7.2.2 Bruce HWP B TS

Power factor at Bruce HWP B TS is often low and does not meet IESO Market Rule requirements. As per section 6.2.3 of the Needs Assessment, the low power factor at Bruce HWP B TS is to be managed by the transmitter and the affected customer.

Recommended Plan

The power factor review conducted by the Local Planning working group, showed that while the power factor of the load occasionally (rather than often as previously identified) does not meet Market Rule requirements there is no negative effect at this time. The investigation is detailed in the Local Planning report [4]. The Local Plan recommends no mitigation is required at this time.

7.3 Customer Delivery Point Performance

7.3.1 Customers Supplied from Circuit 61M18

The performance of delivery points supplied from circuit 61M18, specifically Constance DS and Goderich TS were reviewed. The review is summarized in Appendix F, section F.1.

Recommended Plan and Current Status

To address delivery point performance to Constance DS and Goderich TS, it is recommended that Hydro One Transmission continue to rely on its line and station maintenance programs, as well as capital sustainment projects listed in section 4.0 and in Table 7-1 to improve the overall reliability.

Current Status of Sustainment Work associated 61M18 Delivery Points

The 17 remaining original 1959 structures on circuit 61M18 along with 11 other structures are schedule to be tested over the next 2 years. Those that are determined to be End-Of-Life (in poor condition), will then be replaced in the next 5 years. These replacements will occur under Hydro One's Line Sustainment programs.

7.3.2 Customers Supplied from Circuit L7S

The performance of delivery points supplied from circuit L7S, specifically Centralia TS, Grand Bend East DS, St. Marys TS and the 4 industrial customer connections, were reviewed. The review is summarized in Appendix F, section F.2.

Recommended Plan

To address delivery point performance, it is recommended that Hydro One Transmission undertake a staged approach. Stage 1 will entail a detailed field screening of the line for approximately $154 thousand in 2017. Based on findings from the field screening, work to reduce the frequency of interruptions due to adverse weather should be implemented in 2018 and 2019. Cost for improvements is unknown at this time as it is dependent on actual findings. Performance will then be monitored for 2-3 years to verify improvement. Stage 2 will be based on the monitored performance and may entail strategically installing 115 kV in-line remotely-operated switches on circuit L7S to reduce the duration of interruptions. Switches are currently estimated to cost between $1M to $4M depending on the number of switches and their location. Funding of the staged plan to be as per the OEB-approved Hydro One Customer Delivery Point Performance Standard [EB-2002-0424, updated February 7, 2008]. Capital contribution from customers is not anticipated at this time. If, however, capital contribution is required from customers such financial obligation will be determined using methodology set out in the Transmission System Code.

7.3.3 Customers Supplied from Circuit D10H

The performance of delivery points supplied solely from circuit D10H, specifically Palmerston TS and Elmira TS were reviewed. The review is summarized in Appendix F, section F.3.

Current Status

Consultations with customers supplied from D10H are expected to be undertaken in 2017. Additional assessment and/or infrastructure to adhere to the OEB-approved funding rules for customer delivery point reliability improvements. Improvements may entail installing 115 kV in-line remotely operated switches for approximately $1.5M. Funding of the staged plan to be as per the OEB-approved Hydro One Customer Delivery Point Performance Standard [EB-2002-0424, updated February 7, 2008]. Capital contribution might be required from customers and such financial obligation will be determined using methodology set out in the Transmission System Code.

7.4 Step-Down Transformation Capacity

7.4.1 Hydro One Distribution

The RIP load forecast in conjunction with more recent requests for step-down transformation capacity by Hydro One Distribution at Douglas Point TS indicates that additional step-down transformation capacity is needed.

Current Status

Hydro One Distribution is currently working with its customer to determine their connection capacity requirements, size and timeline. Once the customer's requirements are firm, one of the three "need" scenarios outlined in section 6.4 of this report will be undertaken.

7.5 Transmission Sustainment Plans

As part of Hydro One's transmitter requirements, Hydro One continues to ensure a reliable transmission system by carrying out maintenance programs as well as periodic replacement of equipment based on their condition. Table 7.1 lists Hydro One's major transmission sustainment *projects* in the Region that are currently planned or underway. There is currently no major line sustainment *projects* planned within the next 5 years. Maintenance *programs* such as insulator, shield wire, structure replacements will continue to be carried out in the Region as required based on equipment/asset condition assessments.

Table 7-1: Hydro One Transmission Major Sustainment Initiatives[2]

Station	General Description of Work	Planning In Service Date
Bruce A TS	• Replacement of 230 kV circuit breakers • Uprating of the station strain buses • Replacement of Protections and Control relay building	2019
	• Replacement of 500 kV circuit breakers and switches • Replacement of 2 autotransformers 500/230 kV • Upgrading of Protection and Control equipment	2025
Bruce B SS	• Replacement of 500 kV circuit breakers and switches	2021

[2] Scope and dates as of July 2017 and are subject to change

Centralia TS	• Replace existing 3 transformers with a typical 25/42 MVA 2 transformer arrangement • Replacement of 27.6 kV switchyard • Installation of new PCT Facilities	2019
Detweiler TS	• Replacement of AC and DC station service	2018
	• Replacement of T2 and T4 autotransformers and upgrade to spill containment • Replacement Protection and Control equipment	2021
Hanover TS	• Replacement of T1/T2 transformers and associated switches • Replacement of low voltage circuit breakers and switches • Replacement of Protection and Control systems and CVT's *Additional scope of work currently under development*	2023
Palmerston TS	• Replace existing 3 transformers with a typical 50/83 MVA 2 transformer arrangement. • Replacement of low voltage switches • Replacement of Protection and Control systems with new PCT facilities • Upgrade to AC & DC station services	2019
Seaforth TS	• Replacement of 2 autotransformers 230/115 kV • Replacement of 2 step-down transformers 115/27.6 kV • Replacement of 230kV switches • Upgrade Protection and Control systems • Updated AC & DC station service	2023
Wingham TS	• Complete station refurbishment *Additional scope of work currently under development*	2022

Based on the needs identified in the region thus far and the transmission sustainment plans listed in Table 7-1, consolidation of sustainment and development needs is not necessary at this time.

8. CONCLUSION

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GREATER BRUCE-HURON REGION.

Five near and mid-term needs were identified for the Greater Bruce-Huron Region. They are:

I. Transmission Circuit Capacity on L7S

II. Low power factor at Wingham TS

III. Low power factor at Bruce HWB TS

IV. Customer delivery point performance review on the 115 kV system

V. Step-down transformation capacity at Douglas Point TS

This RIP report addresses all five of these needs and has concluded that no regional plans for needs I, II and III are required at this time. Next Steps, Lead Responsibility, and Timeframes for implementing the regional plans needs IV and V are summarized in the Table 8-1 below.

Table 8-1: Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

No.	Project	Next Steps	Lead Responsibility	In-Service Date	Cost	Needs Mitigated
1	Improve 3L7S Delivery Point Performance	2 Stage Plan	Hydro One Transmission	2017-2023	$154k - TBD	IV
2	Accommodation for Connection Capacity Requests near Kincardine– Hydro One Network Inc. Distribution	Await Customer Direction	Hydro One Distribution	TBD	TBD	V

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Customer CTS #3	115 kV	L7S
Customer CTS #4	115 kV	L7S

APPENDIX B: REGIONAL TRANSMISSION CIRCUITS IN THE GREATER BRUCE-HURON REGION

Location	Circuit Designation	Voltage (kV)
Bruce A TS - Orangeville TS	B4V/B5V	230 kV
Bruce A TS - Detweiler TS	B22D/ B23D	230 kV
Bruce A TS - Owen Sound TS	B27S/B28S	230 kV
Bruce A TS - Douglas Point TS	B20P/B24P	230 kV
Hanover TS – Palmerston TS	D10H-North	115 kV
Seaforth TS - Goderich TS	61M18	115 kV
Seaforth TS - St. Marys TS	L7S	115 kV
Owen Sound TS – Hanover TS	S1H	115 kV

APPENDIX C: DISTRIBUTORS IN THE GREATER BRUCE-HURON REGION

Distributor Name	Station Name	Connection Type
Hydro One Networks Inc.	Constance	Tx
	Centralia TS	Dx
	Grand Bend East DS	Tx
	Douglas Point TS	Dx
	Goderich TS	Dx
	Hanover TS	Dx
	Owen Sound TS	Dx
	Palmerston TS	Dx
	Seaforth TS	Dx
	St. Marys TS	Dx
	Stratford TS	Dx
	Wingham TS	Dx
Erie Thames Power Lines Corporation	Constance DS	Dx
Festival Hydro Inc.	Grand Bend East DS	Dx
	Seaforth TS	Dx
	Stratford TS	Dx
	Festival MTS #1	Tx
Lake Huron Primary Water Supply System	Lake Huron WTP CTS	Tx
Lake Huron Primary Water Supply System	McGillivray R&BP CTS	Tx
West Coast Huron Energy Inc.	Goderich TS	Tx
Enbridge Pipeline Inc.	Enbridge Bryanston CTS	Tx
St. Marys Cement Inc.	St. Marys Cement CTS	Tx

Historical Power Factor	N/A	N/A	N/A
Load Security	no negative impact	no negative impact	no negative impact
Load Restoration	no negative impact	no negative impact	no negative impact
Voltage Performance	no negative impact	no negative impact	no negative impact
CDPP	N/A	N/A	N/A
230/115 kV Autos	no negative impact	no negative impact	no negative impact
230 kV Lines	no negative impact	no negative impact	no negative impact
115 kV Lines	no negative impact	no negative impact	no negative impact
Step down Transformation Capacity	no negative impact	Study shows that there is a slight impact but loading remains within LTR and at least one LV cap must be in-service during summer loading by the end of the study period. This is similar to the Needs Assessment results.	Study shows that the gross winter forecast loading is at the LTR in winter 2023/2024. All summer forecasts show loading is within LTR for the study period.
Bulk System Performance	no negative impact	no negative impact	no negative impact

APPENDIX F: CUSTOMER DELIVERY POINT PERFORMANCE REVIEW

Based on the recommendations from the May 2016 Needs Assessment, 15 customer delivery points were reviewed in detail to assess their reliability performance. Reliability performance of a delivery point is a measure of the frequency of interruption and duration of interruption. The yearly frequency and yearly total duration of interruptions are compared against Hydro One performance standards filed with the OEB, [EB-2002-0424, updated February 7, 2008].

All 15 delivery points are supplied solely from single circuit 115 kV transmission lines and are grouped as follows:

Table F-1 - Customer Delivery Points

Single circuit 115 kV Transmission Line	Station	# of Customer Delivery Points
61M18	Goderich TS	2
	Constance DS	1
L7S	Centralia TS	2
	Grand Bend East DS	1
	St. Mary TS	1
	Industrial Customer # 1	1
	Industrial Customer # 2	1
	Industrial Customer # 3	1
	Industrial Customer # 4	1
D10H -North	Palmerston TS	2
D10H - South	Elmira TS	2

The reliability performance of the delivery points were studied in groups based on their connection point to the transmission system, specifically their 115 kV transmission line supply as shown in Table F-1.

The review of each delivery point included a 10 year review of interruptions between years 2006 and 2015. The interruptions were compared against each delivery points "Group" metrics as defined in the OEB filing as well as each delivery points "Individual Historical Performance" as defined in the OEB filing. Where the yearly performance did not meet either the Group or Individual standards for either frequency or duration of interruptions, Hydro One Transmission classified the delivery point as an "Outlier". Based on a delivery point's Outlier status, their reliability performance is reviewed. The summary of review is given below.

F.1 Delivery Points Supplied by Transmission Line 61M18

In the past, 2006-2010, Goderich TS was classified as a Group Outlier for both frequency and duration of interruption. Recently it is classified as a Group Outlier for duration only. These classifications are mainly due to past equipment failures at Seaforth TS and recently as a consequence of line 61M18 tied to line L7S while L7S experienced interruptions.

Constance DS is not classified as a Group Outlier; however it is occasionally classified as an Individual Outlier for duration of interruption. Although Constance DS is subject to the same line 61M18 interruptions as Goderich TS, it is typically not classified as a Group Outlier because it has less stringent performance metrics due to the smaller amount of load (MW) supplied from it.

The review showed that the root cause of interruptions is due to the performance of the transmission line 61M18 during adverse weather. When 61M18 is interrupted, all load connected to Constance DS and Goderich TS is left unsupplied. As line 61M18 is radial, there are not many options to resupply the load prior to repairing the line. Often building a temporary bypass can take longer than fixing the damaged equipment and the ability to transfer the load to other stations is limited due to the sparse topology of customer distribution systems. Overall, customers supplied from Constance DS and Goderich TS have similar delivery point performance compared to other customers supplied by a single radial circuit and poor delivery point performance compared to other customers supplied by dual circuits. Additionally, a technical review concluded that the transmission line is performing as originally designed with respect to line design security parameters which correspond to a line’s susceptibility to faults caused by external forces such as lightning and storms.

As upgrading the transmission supply to these stations is not economical for neither the customers nor Hydro One Transmission based on the OEB-approved funding rules for customer delivery point reliability improvement, it is recommended for Hydro One Transmission to continue to rely on its Line and Station maintenance and capital sustainment projects to improve the overall reliability performance to delivery points. Based on customer consultations, Goderich Hydro - West Coast Huron Energy Inc., Erie Thames Power and Hydro One Distribution have agreed to this approach and will continue to monitor performance.

F.2 Delivery Points Supplied by Transmission Line L7S

Centralia TS is classified as a Group Outlier for both frequency and duration of interruption. Recently in 2013 and 2014 is has also been classified as an Individual Outlier for duration of interruption.

Grand Bend East DS is classified as a Group Outlier for both frequency (occasionally) and duration (consistently) of interruption, as well as an Individual Outlier for duration.

All four industrial customer delivery points are occasionally classified at a Group Outlier for frequency of interruption; while one of them often is classified as a Group Outlier for duration of interruption. Over the past 3 years, the industrial customer delivery points have often been classified as Individual Outliers for duration.

The review showed that the root cause of interruptions is due to the performance of the transmission line L7S during adverse weather. When L7S is interrupted, all load connected to it is left unsupplied. As line L7S is radial, there are not many options to resupply the load prior to repairing the line. Often building a temporary bypass can take longer than fixing the damaged equipment and the ability to transfer the load to other stations is limited due to the sparse topology of customer distribution systems. Depending on prevailing system conditions, manual switching on the transmission system can be performed to resupply some L7S load from Detweiler TS via 115 kV circuit D8S. Overall, customers supplied from L7S have similar delivery point performance compared to other customers supplied by a single radial circuit and poor delivery point performance compared to other customers supplied by dual circuits. Additionally, a technical review concluded that the transmission line is performing as originally designed with respect to line design security parameters which correspond to a line's susceptibility to faults caused by external forces such as lightning and storms.

Due to the Individual Outlier classification of delivery points supplied from L7S it is recommended that a focused line assessment is undertaken. Although major upgrades to the transmission supply is not economical for neither the customers nor Hydro One Transmission based on the OEB-approved funding rules for customer delivery point reliability improvement, it remains the recommendation for Hydro One Transmission to improve the reliability of transmission line L7S. A two stage approach is prudent. Stage 1 will entail a detailed field screening of the line for approximately $154 k in 2017. Based on findings from the field screening, work to reduce the frequency of interruptions due to adverse weather should be implemented in 2018 and 2019. Cost for improvements is unknown at this time as it is dependent on actual findings. Performance will then be monitored for 2-3 years to verify improvement. It is expected that reduction to the frequency of interruptions will reduce the total duration of interruptions. Stage 2 will be based on the monitored performance and may entail strategically installing 115 kV in-line remotely-operated switches to reduce the duration of interruptions. Switches are currently estimated to cost between $1M to $4M depending on the number of switches and their location.

Based on customer consultations, Festival Hydro, Hydro One Distribution and the industrial customers have agreed to this approach.

F.3 Delivery Points Supplied by Transmission Line D10H

115 kV circuit D10H between Detweiler TS and Hanover TS is operated normally-open at Palmerston TS whereby Palmerston TS is normally supplied from Hanover TS (D10H-North) while Elmira TS is normally supplied from Detweiler TS (D01H – South).

Over the past 3 years, Palmerston TS has been classified as a Group Outlier for both frequency and duration of interruption. It has not been classified as an Individual Outlier over the 10 year review period.

Over the past 3 years, Elmira TS has been classified as a Group Outlier for both frequency and duration of interruption. It has been classified as an Individual Outlier once in the 10 year review period; specifically in 2013 for frequency of interruption.

The review showed that the root cause of interruptions is due to the performance of the transmission lines D10H-North and D10H-South during adverse weather. When D10H-North is interrupted, all load connected to Palmerston TS is left unsupplied. When D10H-South is interrupted, all load connected to Elmira TS is left unsupplied. Since there are several 115 kV in-line switches along D10H and depending on prevailing system conditions, circuit D10H can be reconfigured to supply Palmerston TS and Elmira TS from either the Hanover TS or Detweiler TS ends. 115 kV in-line switches at Palmerston TS have the capability to be operated remotely. There are two other manual-operated switches surrounding the tap to Elmira TS.

Overall, customers supplied from Palmerston TS and Elmira TS have similar delivery point performance compared to other customers supplied by a single radial circuit and poor delivery point performance comparable to other customers supplied by dual circuits. Additionally, a technical review concluded that the transmission line is performing as originally designed with respect to line design security parameters which correspond to a line’s susceptibility to faults caused by external forces such as lightning and storms.

Consultations with customers supplied from D10H are expected to be undertaken in 2017. Additional assessment and/or infrastructure to adhere to the OEB-approved funding rules for customer delivery point reliability improvements. Improvements may entail installing 115 kV in-line remotely operated switches for approximately $1.5M.

APPENDIX G: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DCF	Discounted Cash Flow
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GATR	Guelph Area Transmission Reinforcement
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group

Niagara
Regional Infrastructure Plan ("RIP")

March 28th 2017

Canadian Niagara Power Inc.
Grimsby Power Inc.
Alectra Utilities
Hydro One Networks Inc. (Distribution)
Niagara Peninsula Energy Inc.
Niagara-On-the-Lake Hydro Inc.
Welland Hydro-Electric System Corporation

The Niagara Region includes the municipalities of City of Port Colborne, City of Welland, City of Thorold, City of Niagara Falls, Town of Niagara-On-The-Lake, City of St. Catharines, Town of Fort Erie, Town of Lincoln, Township of West Lincoln, Town of Grimsby, Township of Wainfleet, and Town of Pelham.

The Needs Assessment ("NA") report for the Niagara Region was completed on April 30th, 2016 (see attached). The report concluded that there were only two needs in the Region and that they should be addressed as follows:

- Thermal overloading of 115kV circuit Q4N: Addressed in a Local Plan ("LP") report.

The loading constraints on 115kV circuit Q4N was addressed in a LP report led by Hydro One Networks Inc. and published on November 11th, 2016. The report concluded that Hydro One already has plans to replace the existing section of conductor between Sir Adam Beck SS #1 and Portal JCT with a 910A continuous rating conductor at 93°C as part of their Beck #1 SS Refurbishment project. The expected in-service date for this conduction section upgrade is December 2019.

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no further regional coordination was required, the attached NA and LP reports will be deemed to form the RIP for the Niagara Region.

The next planning cycle for the region will take place within five years of the start of this cycle (2021) or earlier, should there be a new need identified in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks Inc.

DISCLAIMER

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Niagara region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

Region	Niagara (the "Region")		
Lead	Hydro One Networks Inc. ("Hydro One")		
Start Date	October 15, 2015	End Date	April 30th 2016

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the Niagara Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the Niagara Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 regions is complete and has been initiated for Group 3 Regions. The Niagara Region belongs to Group 3. The NA for this Region was triggered on October 15, 2015 and was completed on April 30th 2016

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2025. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the Independent Electricity System Operator (IESO), and Hydro One transmission provided information for the Niagara Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2015 to 2024). The assessment reviewed available information, load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Needs

A. Transmission Lines & Ratings The 230kV and 115kV lines are adequate over the study period with a section of 115kV circuit Q4N being the exception.
B. 230 kV and 115 kV Connection Facilities The 230kV and 115kV connection facilities in this region are adequate over the study period.

System Reliability, Operation and Restoration Review

There are no known issues with system reliability, operation and restoration in the Niagara region.

Aging Infrastructure / Replacement Plan

Within the regional planning time horizon, the following sustainment work is currently planned by Hydro One in the region:

- DeCew Falls SS: Circuit Breaker Replacement (2017)
- Sir Adam Beck SS #1: 115kV Refurbishment Project (2018)
- 115kV Q11/Q12S Line Refurbishment from Glendale TS to Beck SS #1 (2019)
- Carlton TS: Switchgear Replacement (2020)
- Sir Adam Beck SS #2: 230kV Circuit Breakers Replacement (2020)
- Glendale TS: Station Refurbishment and Reconfiguration (2021)
- Stanley TS: Station Refurbishment (2021)
- Thorold TS: Transformer Replacement (2021)
- Crowland TS: Transformer Replacement (2021)

Based on the findings of the Needs Assessment, the study team recommends that thethermal overloading of 115kV circuit Q4N shouldbe further assessed as part of a Local Plan. No further regional coordination or planning is required.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 Introduction

This Needs Assessment (NA) report provides a summary of needs that are emerging in the Niagara Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the Niagara Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain local type of needs if straight forward wires solutions can address a need. Ultimately, assessment and findings of the local plans are incorporated in the RIP for the region.

This report was prepared by the Niagara Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

Table 1: Study Team Participants for Niagara Region

No.	Company
1	Hydro One Networks Inc. (Lead Transmitter)
2	Independent Electricity System Operator
3	Canadian Niagara Power Inc.
4	Grimsby Power Inc.
5	Haldimand County Hydro Inc
6	Horizon Utilities Corp.
7	Hydro One Networks Inc. (Distribution)
8	Niagara Peninsula Energy Inc.
9	Niagara on the Lake Hydro Inc.
10	Welland Hydro Electric System Corp.

2 Regional Issue / Trigger

The NA for the Niagara Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Niagara Region belongs to Group 3.

3 Scope of Needs Assessment

This NA covers the Niagara Region over an assessment period of 2015 to 2024. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 Niagara Region Description and Connection Configuration

For regional planning purposes, the Niagara region includes the City of Port Colborne, City of Welland, City of Thorold, City of Niagara Falls, Town of Niagara-on-the-Lake, City of St. Catharines, Town of Fort Erie, Town of Lincoln, Township of West Lincoln, Town of Grimsby, Township of Wainfleet, and Town of Pelham. Haldimand County has also been included in the regional infrastructure planning needs assessment for Niagara region. A map of the region is shown below in Figure 1.

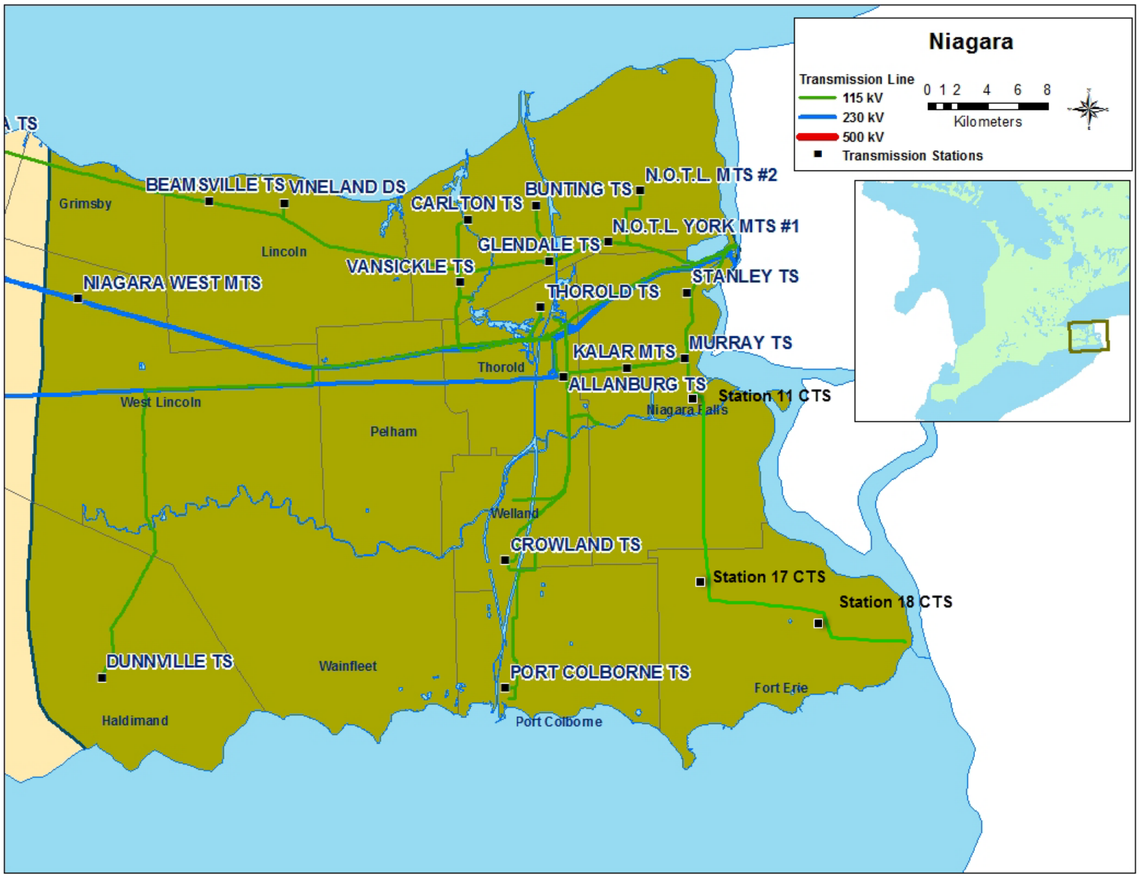

Figure 1: Niagara Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied mainly by the local generation from Sir Adam Beck #1, Sir Adam Beck #2, Decew Falls GS, Thorold GS and the autotransformers at Allanburg TS.

Bulk supply is provided through the 230kV circuits (Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, and Q35M) from Sir Adam Beck #2 SS. These circuits connect this region to Hamilton/Burlington.

The Niagara Region has the following local distribution companies (LDC):

- Canadian Niagara Power Inc.
- Grimsby Power Inc.
- Haldimand County Hydro Inc.
- Horizon Utilities
- Hydro One Distribution Inc.
- Niagara Peninsula Energy Inc.
- Niagara on the Lake Hydro Inc.
- Welland Hydro Electric System Corporation

Large transmission connected customers in the area will not actively participate in the regional planning process, however their load forecasts will used in determining regional supply needs.

4 Inputs and Data

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- Actual 2013 regional coincident peak load and station non-coincident peak load provided by IESO;
- Historical (2012-2014) net load and gross load forecast (2015-2024 provided by LDCs and other Transmission connected customers;
- Conservation and Demand Management (CDM) and Distributed Generation (DG) data provided by IESO;
- Any known reliability and/or operating issues conditions identified by LDCs or the IESO;
- Planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Load Forecast

As per the data provided by the study team, the gross load in region is expected to grow at an average rate of approximately 0.61% annually from 2015-2024.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. With these factors in place, the total regional load is expected to decrease at an average rate of approximately 0.26% annually from 2015-2024.

5 Needs Assessment Methodology

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is summer peaking so this assessment is based on summer peak loads.
2. Forecast loads are provided by the Region's LDCs.
3. Load data for the industrial customers in the region were assumed to be consistent with historical loads.
4. Accounting for (2), (3), above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG are analyzed to determine if the needs can be deferred. A gross and net non-coincident peak load forecast was used to perform the analysis for this report.

5. Review impact of any on-going and/or planned development projects in the Region during the study period.
6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR). Summer LTR ratings were reviewed to assess the worst possible loading scenario from a ratings perspective.
8. Extreme weather scenario factor at 1.037 was also assessed for capacity planning over the study term.
9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their summer long-term emergency (LTE) ratings. Thermal limits for transformers are acceptable using summer loading with summer 10-day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.

- With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 Results

6.1 Transmission Capacity Needs

230/115 kV Autotransformers

The 230/115kV transformers supplying the region are adequate for loss of single unit.

Transmission Lines & Ratings

The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

The 115 kV circuits supplying the Region are adequate over the study period with Q4N as an exception between Sir Adam Beck SS #1 x Portal Junction.

230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station summer peak load forecast provided by the study team. All stations in the area have adequate supply capacity for the study period even in the event of extreme weather scenario.

6.2 System Reliability, Operation and Restoration

6.2.1 Load Restoration

Load restoration is adequate in the area and meet the ORTAC load restoration criteria.

The needs assessment did not identify any additional issues with meeting load restoration as per the ORTAC load restoration criteria.

6.2.2 Thermal Overloading on Q4N Section

Under high generation scenarios at Sir Adam Beck GS #1, the loading on the *Beck SS #1 x Portal Junction* section (egress out from the GS) of 115kV circuit Q4N can exceed circuit ratings. Hydro One already has plans to address this issue as part of the Beck SS #1 Refurbishment Project.

6.2.3 Power Factor at Thorold TS

A few instances (<54 hours / year) of power factor below 0.9 (between 0.89 - 0.9) were observed at the HV side of Thorold TS. Hydro One Distribution will investigate these instances and work with Distribution customers to address.

7 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers and power transformers during the study period. At this time, the following sustainment work is planned at the following stations:

- DeCew Falls SS Circuit Breaker Replacement (2017)
- Sir Adam Beck SS #1 115kV Refurbishment Project (2018)
- 115kV Q11/Q12S Line Refurbishment from Glendale TS to Beck SS #1 (2019)
- Carlton TS; Switchgear Replacement (2020)
- Sir Adam Beck SS #2 230kV Circuit Breakers Replacement (2020)
- Glendale TS; Station Refurbishment and Reconfiguration (2021)
- Stanley TS; Station Refurbishment (2021)
- Thorold TS; Transformer Replacement (2021)
- Crowland TS; Transformer Replacement (2021)

8 Recommendations

Based on the findings and discussion in Section 6 and 7 of this report, the study team recommends that no further regional coordination or further planning is required. The region will be reassessed within five years as part of the next planning cycle.

9 Next Steps

No further Regional Planning is required at this time. The Niagara Region Regional Planning will be reassessed during the next planning cycle or at any time should unforeseen conditions or needs warrant to initiate the regional planning for the region.

Disclaimer

This Local Planning Report was prepared for the purpose of developing wires options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the Niagara Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, “the Authors”) make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared (“the Intended Third Parties”), or to any other third party reading or receiving the Local Planning Report (“the Other Third Parties”), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	Niagara Region ("Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	16 May 2016	**END DATE**	1 November 2016

1. INTRODUCTION

The purpose of this Local Planning ("LP") report is to develop and recommend a preferred wires solution that will address the local needs identified in the Needs Assessment (NA) report for the Niagara Region. The development of the LP report is in accordance with the regional planning process as set out in the Planning Process Working Group ("PPWG") Report to the Ontario Energy Board's ("OEB") and mandated by the Transmission System Code ("TSC") and Distribution System Code ("DSC").

2. LOCAL NEEDS REVIEWED IN THIS REPORT

This report reviewed the potential thermal rating violation for the Beck SS #1 x Portal Junction section of the 115kV Q4N circuit (egress out from Sir Adam Beck GS #1).

3. OPTIONS CONSIDERED

The following options were considered:

- Option 1: Status Quo
- Option 2: Uprate Circuit Section

4. PREFERRED SOLUTIONS

Option 2 is the preferred option. The uprating of limiting section of the circuit is included in Hydro One's Sustainment plan.

5. RECOMMENDATIONS

It is recommended that the circuit section upgrade proceed with current with an expected in-service date of December 2019.

TABLE OF CONTENTS

LIST OF FIGURES

1 Introduction

The Needs Assessment (NA) for the Niagara Region ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. The NA for the Niagara Region was prepared jointly by the study team, including LDCs, Independent Electric System Operator (IESO) and Hydro One. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the Region over the next ten years (2015 to 2024) and recommended that they should be further assessed through the transmitter-led Local Planning (LP) process.

As part of the NA report for the Niagara Region, it identified that under high generation scenarios at Sir Adam Beck GS #1, the loading on the Beck SS #1 x Portal Junction section (egress out from the GS) of 115kV circuit Q4N can exceed circuit ratings in IESO's System Impact Assessment for the Sir Adam Beck-1 GS – Conversion of units G1 and G2 to 60 Hz

This Local Planning report was prepared by Hydro One Networks Inc. ("HONI"). This report captures the results of the assessment based on information provided by LDCs and HONI.

2 Regional Description and Circuit Q4N Description

Sir Adam Beck GS #1 is an 115kV hydroelectric generating station located on the Niagara Escarpment north of Niagara Falls in Queenston. Geographically, it roughly borders Highway 405 and the Canadian-American border via the Niagara River.

Electrical supply from Sir Adam Beck GS #1 is currently provided through eight (8) OPG generators connected to Hydro One's 115kV solid 'E' bus inside the station. Supply to the local 115kV area is delivered via five (5) Hydro One circuits (Q2AH, Q3N, Q4N, Q11S, Q12S) from 115kV 'E' bus within the power house. The 115 kV 'E' bus serves as a switching station for the Hydro One network as well as a connection facility for OPGI's generators. The generators, transformers and circuits on the 'E' bus are sectionalized via switches.

A single line diagram is shown of the 115 kV system originating from the 115kV Sir Adam Beck GS #1 in Figure 1.

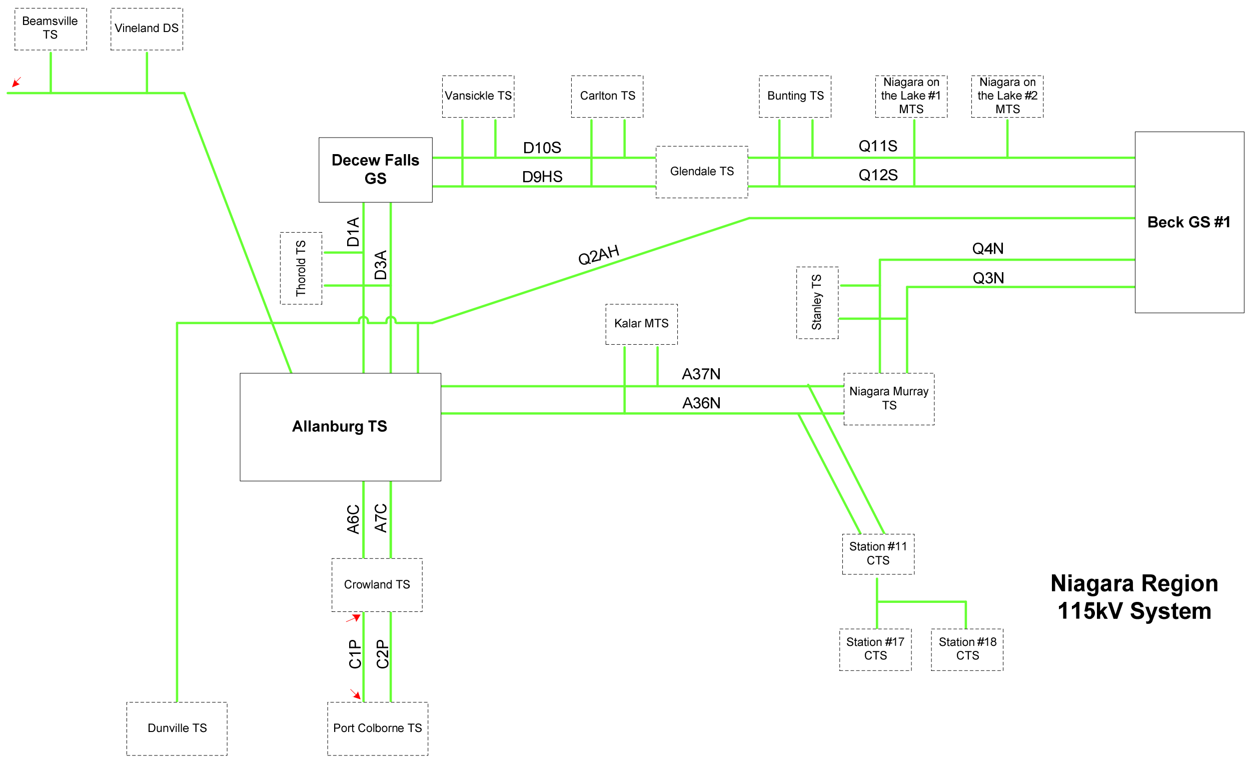

Figure 1: Single Line Diagram – Niagara Region 115kV System

From the NA report for the Niagara Region, a possible thermal limit issue on a section of the circuit Q4N was identified. Q4N is an approximately 9 km long, 115kV radial circuit from Sir Adam Beck GS #1, supplying Stanley TS and Niagara Murray TS.

The section of Q4N identified in the NA comprises of the section from Sir Adam Beck GS #1 to Portal Junction. This section of circuit is shown in Figure 2.

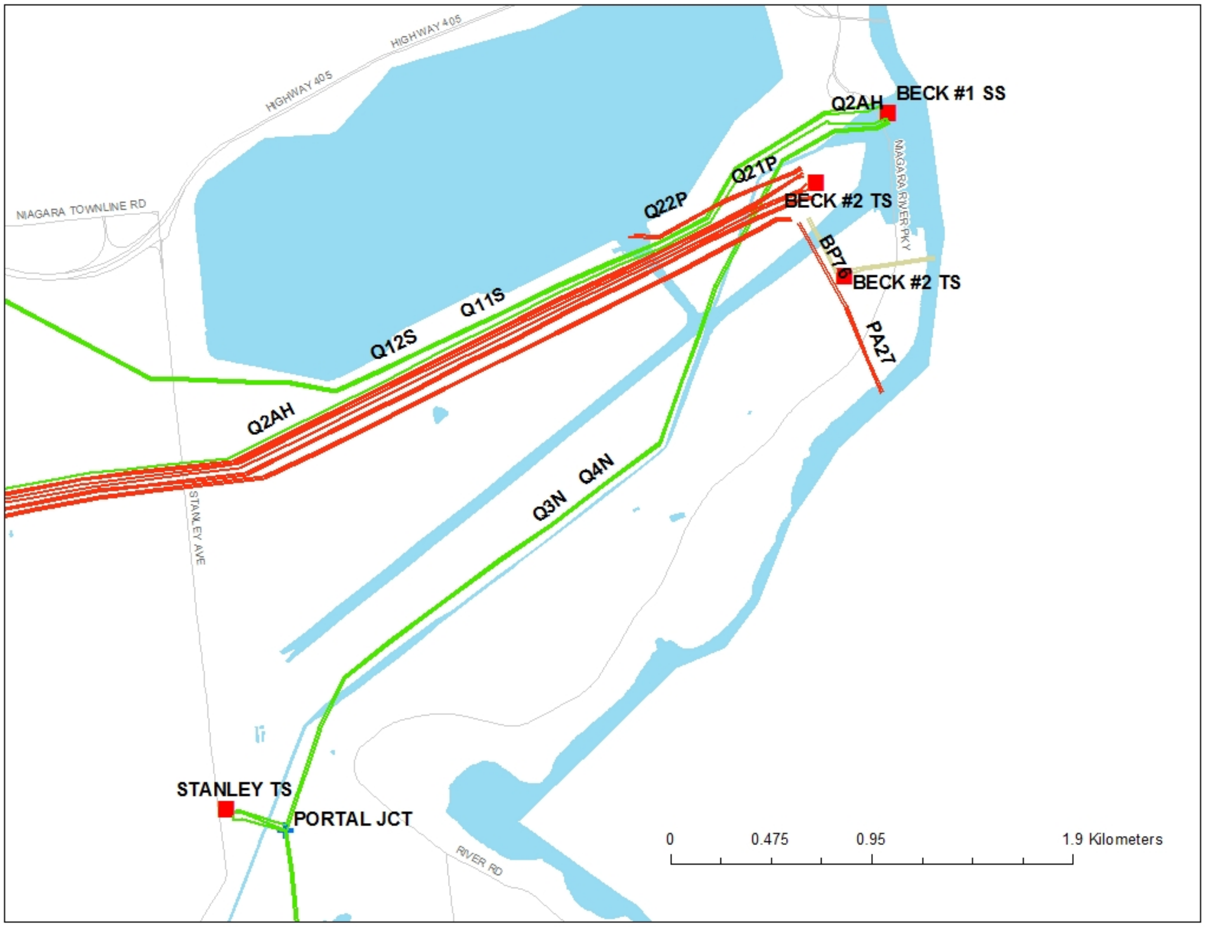

Figure 2: Single Line Diagram – Q4N from Beck #1 SS to Portal Junction

3 Local Niagara Need (Q4N)

In the past decade, OPG has been steadily increasing the power output of their generators with station upgrades.

In the IESO SIA for "Sir Adam Beck-1 GS – Conversion of units G1 and G2 to 60 Hz" it was identified that the thermal loading on circuit section Q4N from Beck #1 SS to Portal junction exceeds its continuous rating by 109.6% at total generation output of Sir Adam Beck #1 GS. This study was based on 2018 summer peak demand with high generation dispatch in the 115 kV transmission system in the vicinity with the existing 8 generators and 2 future generators (G1 and G2) at full output. This thermal loading is based on an ambient 35ºC temperature condition with 4 km/hr wind speed during daytime.

Reducing the generation output of Sir Adam Beck #1 GS from its maximum capacity of 556 MW to 509 MW reduces the loading on Q4N (Beck #1 SS by Portal Junction) to below its continuous rating.

4 Study Result / Options Considered

The conductor on a 64m section of the 115kV circuit Q4N between Sir Adam Beck SS #1 and Portal Jct. is comprised of 605.0 kcmil aluminum, 54/7 ACSR. The continuous rating for this type of conductor at 93^{o}C is 680A. The options considered are outlined below.

4.1 Option 1: Status Quo

Status Quo is not an option because there is a risk that for maximum generation dispatch in extreme weather conditions. Under these conditions generation would have to be curtailed to meet line thermal rating requirements and thus causing financial losses to customer.

4.2 Option 2: Uprate Conductor Section

Hydro One has plans already in place to replace the existing section of conductor with a 910A continuous rated conductor at 93^{o}C as part of their Beck #1 SS Refurbishment project. This will enable this section of circuit to meet all pre and post contingency thermal limits during max generation and under extreme weather conditions.

5 Recommendations

It is recommended that Hydro One continues with their sustainment plans (Option 2) on replacing the section of the 115kV circuit Q4N between Sir Adam Beck SS #1 and Portal Jct. with a larger ampacity conductor (increase of 680A to 910A).

The expected in-service date for this conduction section upgrade is December 2019.

North/East of Sudbury
Regional Infrastructure Plan ("RIP")

April 13, 2017

Northern Ontario Wires Inc.
Hearst Power Ltd.
North Bay Hydro Distribution Ltd.
Hydro One Networks Inc. (Distribution)

North/East of Sudbury Region is the area roughly bordered by Moosonee on the North, Hearst on the North-West, Ferris South and Kirkland Lake on the East.

The Local Planning ("LP") report for the North/East of Sudbury Region was completed on August 8, 2016 (see attached), and identified the following needs in the region:

- Timmins TS/Kirkland Lake TS – Voltage Regulation Issues:

In the LP report, the study team acknowledged that the Timmins TS 115kV bus may experience voltages below ORTAC requirements following a contingency to both Porcupine TS K1K4 and K1K2 breakers. Operating measures are established to control the voltage decline post contingency, and the study team concluded no action is currently required. Hydro One will continue to monitor Timmins area load growth to ensure operating measures outlined in the LP report continue to be effective for voltage regulations.

The LP also report concluded that corrective actions to control voltage violations on the system may be required for any new loads in the Kirkland Lake or Dymond area.

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no further regional coordination was required, the attached NA and LP reports will be deemed to form the RIP for the North/East of Sudbury Region.

The next planning cycle for the region will take place within five years of the start of this cycle (2021) or earlier, should there be a new need identified in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks Inc.

DISCLAIMER

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the North & East of Sudbury Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, “the Authors”) make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared (“the Intended Third Parties”), or to any other third party reading or receiving the Local Planning Report (“the Other Third Parties”), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	North & East of Sudbury (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	May 9, 2016	**END DATE**	November 30, 2016

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only option and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the North & East of Sudbury Region dated April 15, 2016. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

Based on Section 7 of the NA report, the study team recommended that no further coordinated regional planning is required to address the needs in the North & East of Sudbury region. These needs are local in nature and will be addressed by wires options through local planning led by Hydro One with participation of the impacted LDC.

2. LOCAL NEEDS ADDRESSED IN THIS REPORT

The Timmins and Kirkland Lake area voltage regulation are local needs addressed in this report.

3. OPTIONS CONSIDERED

Hydro One (Transmitter) and Hydro One Distribution (LDC) have considered addressing the Timmins TS voltage regulation need with the following options;
Alternative 0 – Status Quo.
Alternative 1 - Implement a Load Rejection Scheme on T61S and P7G

Hydro One (Transmitter) and Hydro One Distribution (LDC) have agreed that Alternative 0 – Status Quo is the only option to be considered for Kirkland Lake TS voltage regulation need.

See Section 3 for further detail.

4. PREFERRED SOLUTION

The preferred solution at this time for both the Timmins TS and Kirkland Lake TS voltage regulation needs are Alternative 0 – Status Quo. See Section 4 for details.

5. NEXT STEPS

The next steps are summarized in section 5

[This page is intentionally left blank]

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 Introduction

The Needs Assessment (NA) for the North & East of Sudbury ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address some specific station capacity needs. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the North & East of Sudbury Region over the next ten years (2016-2026) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

1.1 North & East of Sudbury Region Description and Connection Configuration

The North & East of Sudbury Region are bounded by regions of North Bay, Timmins, Hearst, Moosonee, Kirkland Lake and Dymond. A map of the region is shown below in Figure 1.

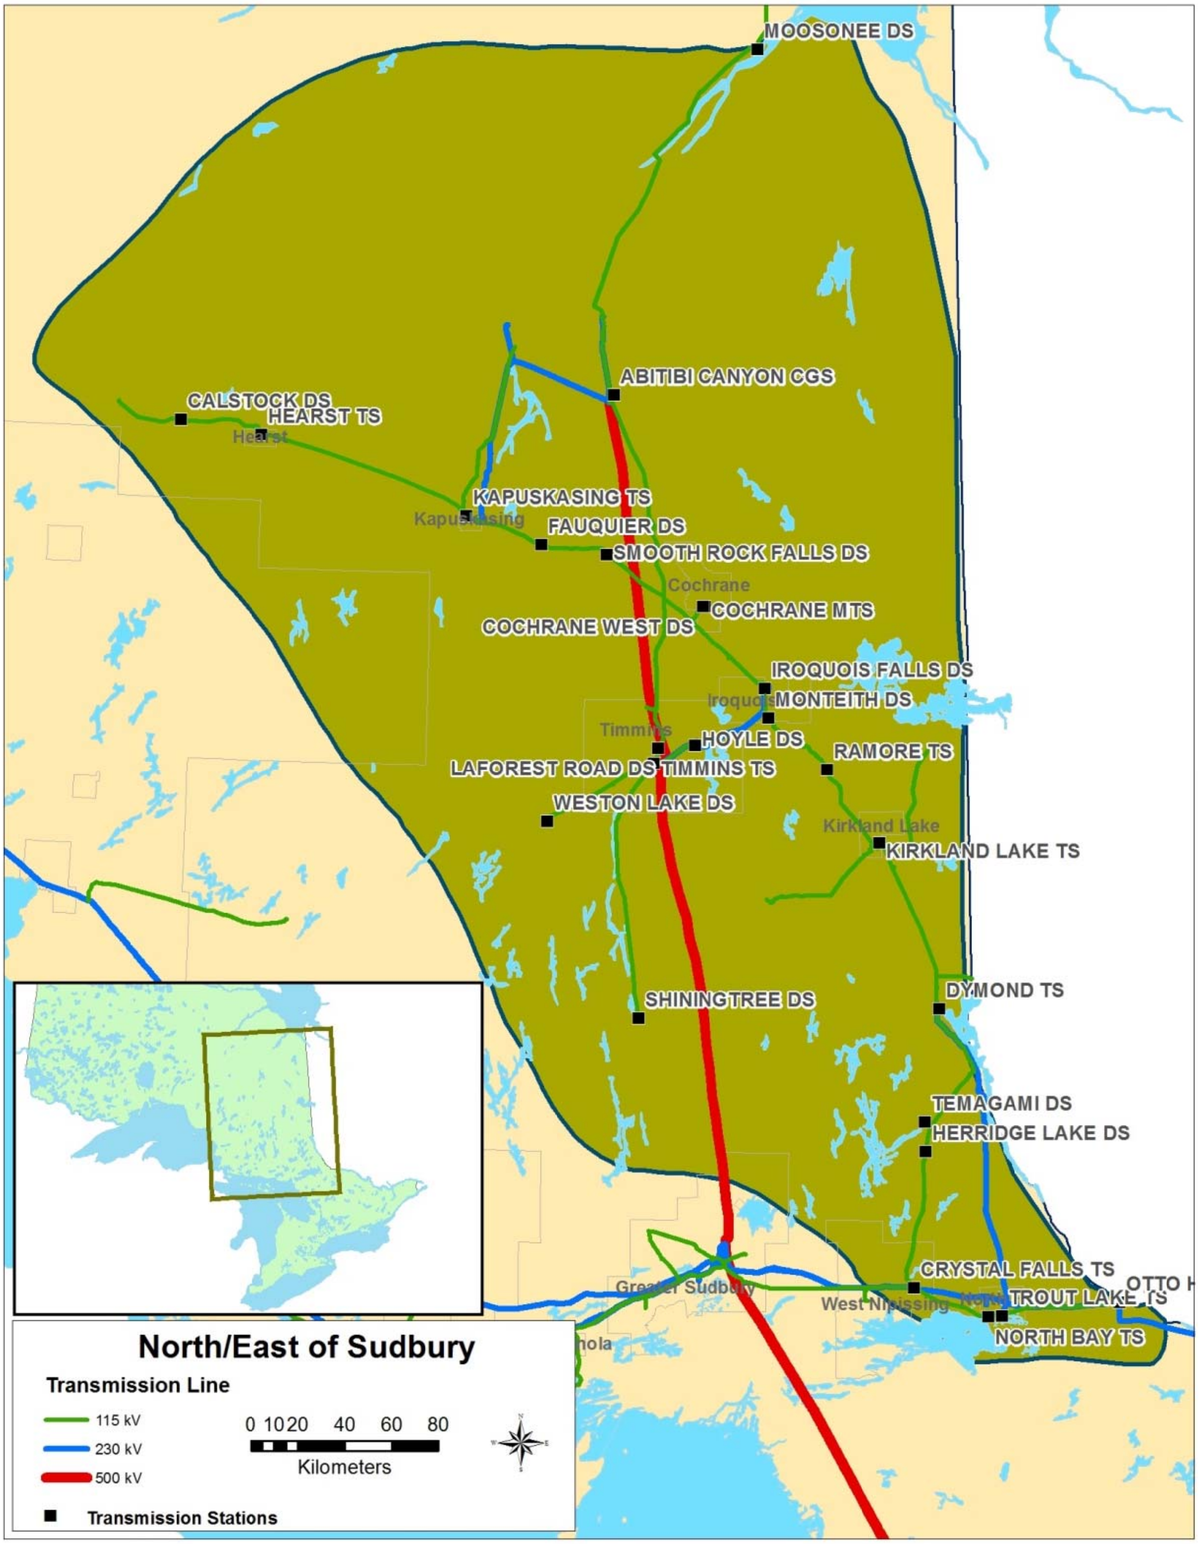

Figure 1: North & East of Sudbury Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. This area is further reinforced through the 500kV circuits P502X and D501P connecting Pinard TS to Hanmer TS. This region has the following four local distribution companies (LDC):

Hydro One Networks (distribution)
Northern Ontario Wires Inc
Hearst Power Ltd
North Bay Hydro Distribution Ltd.

2 Area Needs

2.1 North & East of Sudbury Region Needs

As an outcome of the NA process, the study team identified voltage regulation issues at Timmins TS and Kirkland Lake TS which are addressed in this report. Local planning was recommended, and Hydro One as the transmitter, with the impacted LDC further undertook planning assessments to address the following needs;

- Timmins TS voltage regulation - The loss of Porcupine TS 115kV circuit breakers (K1K4 and K1K2) may result in voltage declines at Timmins TS 115kV bus in excess of 10%. This is considered an n-1-1 contingency and load rejection following the loss of the second element was proposed by IESO to improve post contingency voltage performance. See Figure 3 – Timmins area connection diagram for reference.

- Kirkland Lake TS voltage regulation - The loss of Ansonville T2 and D3K may result in voltage declines at Kirkland Lake TS 115kV bus in excess of 10%. This is considered an n-1-1 contingency and all new loads in the area will be required to participate in a local load rejection scheme to help improve post contingency voltage performance.

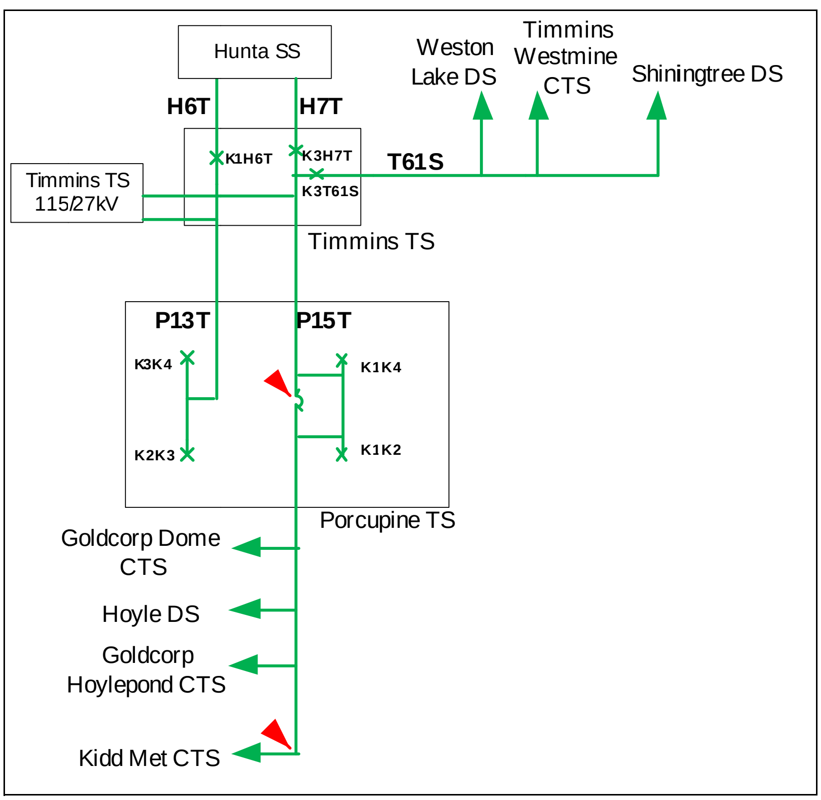

Figure 3: Timmins area connection diagram

3 Alternatives Considered

3.1 Timmins TS Voltage regulation

Alternative 1 – Status Quo.

No further action is required at this time. Hydro One and LDC will monitor the loads and voltages in the area in the upcoming years. Further review of this issue will be undertaken in the next planning cycle or earlier if there is evidence that load cannot be served or system cannot be operated in a safe, secure and reliable manner. Voltage issues can be addressed with operating procedures which are presently in place without any use of load rejection.

Alternative 2 – Implement Load Rejection on T61S, P7G, P15T to control Timmins TS voltages

This option will require expansion of the Northeast LR/GR scheme to include tripping of the Hydro One 115kV T61S, P7G, and P15T circuits upon contingency of both Porcupine TS K1K4 and K1K2 circuit breakers. This will allow for automatic load rejection of approximately 40MW of load.

Table 2: Budgetary Cost for Alternatives

Options Considered	Cost
Alternative 1 – Hydro One to assess voltage performance with no immediate investment.	--
Alternative 2 – Expand Northeast Special Protection Scheme (SPS) to include P15T, P7G, T61S circuits	$2M

3.2 Kirkland Lake TS Voltage regulation

Alternative 1 – Status Quo. See details in section 4 below.

4 Preferred Solution and Reasoning

4.1 Timmins TS Voltage regulation

Hydro One Networks and Hydro One Distribution have reviewed all alternatives and the preferred solution at this time is, Alternative 1 – Status Quo.

The study team acknowledges that Timmins TS 115kV bus may experience voltages below ORTAC requirements following a contingency to both Porcupine TS K1K4 and K1K2 breakers. The possibility of this scenario is remote and there are established operating measures in place should the first Porcupine TS breaker (either K1K4 or K1K2) be placed out of service. The following control measures are taken which help alleviate the voltage decline post contingency.

- Open Timmins TS LV breaker to offload Timmins TS from P15T
- Transfer P7G load to P91G by closing breaker B5L2 at Kidd Creek Metsite and open Porcupine TS switch 30-P7G
- Place one Abitibi Canyon 115kV unit on condenser mode.

Hydro One Networks and Hydro One Distribution have agreed that these operating measures are a preferred alternative to load rejection. In addition, implementing the load rejection scheme will expose the customers in the area to unnecessary interruption due to misoperation of the load rejection scheme.

Hydro One will continue to monitor Timmins area load growth from both LDCs and industrial customers to ensure load growth (if any) does not make voltage situation worse whereby the above operating measures are no longer effective. The next planning cycle will take place within five years and an investment can be triggered at any time should there be a situation where load cannot be served or system cannot be operated safely and reliably.

4.2 Kirkland Lake TS Voltage Regulation

Hydro One Networks and Hydro One Distribution agree that new loads in the Kirkland Lake or Dymond area may be subject to participate in an under voltage load rejection scheme as part to help control voltages in the area post contingency. Presently there is no load growth in the area over the study period. Investments are not required at this time for existing LDC loads and Hydro One will monitor load growth in the area and take corrective action as required or when instructed to do so by the IESO as proponent connection requirements. These will be identified during the load connection process after the connection applications and will be implemented by Hydro One.

5 Next Steps

A summary of the next steps, actions/solutions and timelines required to address the local needs are as follows:

Table 3: Solutions and Timeframe

Need	**Action / Recommended Solution**	**Lead Responsibility**	**Timeframe**
Timmins TS Voltage Regulation	• No Immediate action required • Hydro One and LDC to monitor area load growth	Hydro One Networks	Five years
Kirkland Lake TS Voltage Regulation	• No Immediate action required • Connection requirements for new transmission or distribution connections to be implemented as identified during system studies.	Hydro One Networks	N/A

NEEDS ASSESSMENT REPORT

Region: North and East of Sudbury

Date: April 15, 2016

Prepared by: North and East of Sudbury Region Working Group

North & East of Sudbury Working Group	
Organization	**Name**
Hydro One Networks Inc. (Lead Transmitter)	Kirpal Bahra Qasim Raza
Independent Electricity System Operator	Chris Reali Philip Woo
Hydro One Networks Inc. (Distribution)	Richard Shannon Daniel Boutros
Northern Ontario Wires Inc	Dan Boucher
Hearst Power Ltd	D Sampson J Richard
North Bay Hydro Distribution Ltd	Matt Payne

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the North & East of Sudbury region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by Working Group participants.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	North & East of Sudbury (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 15, 2015	**END DATE**	April 15, 2016

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the North & East of Sudbury Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the North & East of Sudbury Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 regions is complete and has been initiated for Group 3 Regions. The North & East of Sudbury Region belongs to Group 3, triggered on October 15, 2015 and completed on April 17, 2016

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2026. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Working Group participants included representatives from LDCs, the Independent Electricity System Operator (IESO), and Hydro One. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective is to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2016 to 2026). The assessment reviewed available information, load forecasts and included single contingency analysis to confirm needs, if and when required.

6. RESULTS - TRANSMISSION NEEDS

A. 500/230kV Autotransfomers
The 500/230kV Autotransformers supplying the regional are adequate over the study period for the loss of a single 500/230kV unit.

B. 500/115kV Autotransfomers
The 500/115kV Autotransformers supplying the regional are adequate over the study period for the loss of a single 500/115kV unit

C. 230/115 kV Autotransformers
The 230/115kV Autotransformers supplying the regional are adequate over the study period for the loss of a single 230/115kV unit

D. Transmission Lines & Ratings
The 500kV, 230kV transmission lines are adequate over the study period.

Sections of the 115kV H9K circuit may experience thermal overloads during high generation scenarios. This is a bulk system issue and will be addressed jointly with the IESO outside of regional planning.

E. 230 kV and 115 kV Connection Facilities
The 230kV and 115kV connection facilities in this region are adequate over the study period.

F. Outage Condition resulting in P15T,P7G and T61S radially connected to Timmins TS
The loss of K1K4 and K1K2 circuit breakers at Porcupine TS can result in excessive voltage declines at Timmins TS 115kV bus

G. Ansonville T2 or D3K Outages
With Ansonville T2 or D3K out of service, the loss of the other can result in excessive voltage decline at the Kirkland Lake TS 115kV bus.

System Reliability, Operation and Restoration Review

Circuit reliability in the region is acceptable, and Hydro One will continue to monitor performance of supply stations and circuits to ensure customer delivery performance criteria are met.

Restoration requirements for the loss of one element can be met by Hydro One.
Restoration requirements for the loss of up to two elements can be met by Hydro One.

Aging Infrastructure / Replacement Plan

Within the regional planning time horizon, the following work is part of Hydro One approved sustainment business plan

Dymond TS (T3/T4) transformers (2016)
Kirkland Lake TS (T12/T13) transformers (2017)
Timmins TS (T63/T64) with single 83MVA (2016)
Otto Holden TS (T3/T4) autotransformers, and 115kV circuit breakers (2019)

7. RESULTS – NEEDS ASSESSMENT REPORT

Based on the findings of the Needs Assessment, the Working Group recommends that no further regional coordination is required and following needs identified be further assessed as part of Local Planning:

Timmins TS / Kirkland Lake TS – Voltage Regulation Issues

TABLE OF CONTENTS

LIST OF FIGURES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the North & East of Sudbury Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the North & East of Sudbury Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. If localized wires only solutions do not require further coordinated regional planning, the SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by Hydro One Inc ("Hydro One") on behalf of the North & East of Sudbury Region NA Working Group (Table 1). The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

Table 1: Working Group Participants for North & East of Sudbury Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
2.	Independent Electricity System Operator
3.	Northern Ontario Wires Inc
4.	Hydro One Networks Inc. (Distribution)
5.	Hearst Power Ltd
6.	North Bay Hydro Inc.

2 REGIONAL ISSUE / TRIGGER

The NA for the North & East of Sudbury Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The North & East of Sudbury Region belongs to Group 3.

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the North & East of Sudbury Region over an assessment period of 2016 to 2026. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

North & East of Sudbury Region Description and Connection Configuration

The North & East of Sudbury Region are bounded by regions of North Bay, Timmins, Hearst, Moosonee, Kirkland Lake and Dymond. A map of the region is shown below in Figure 1.

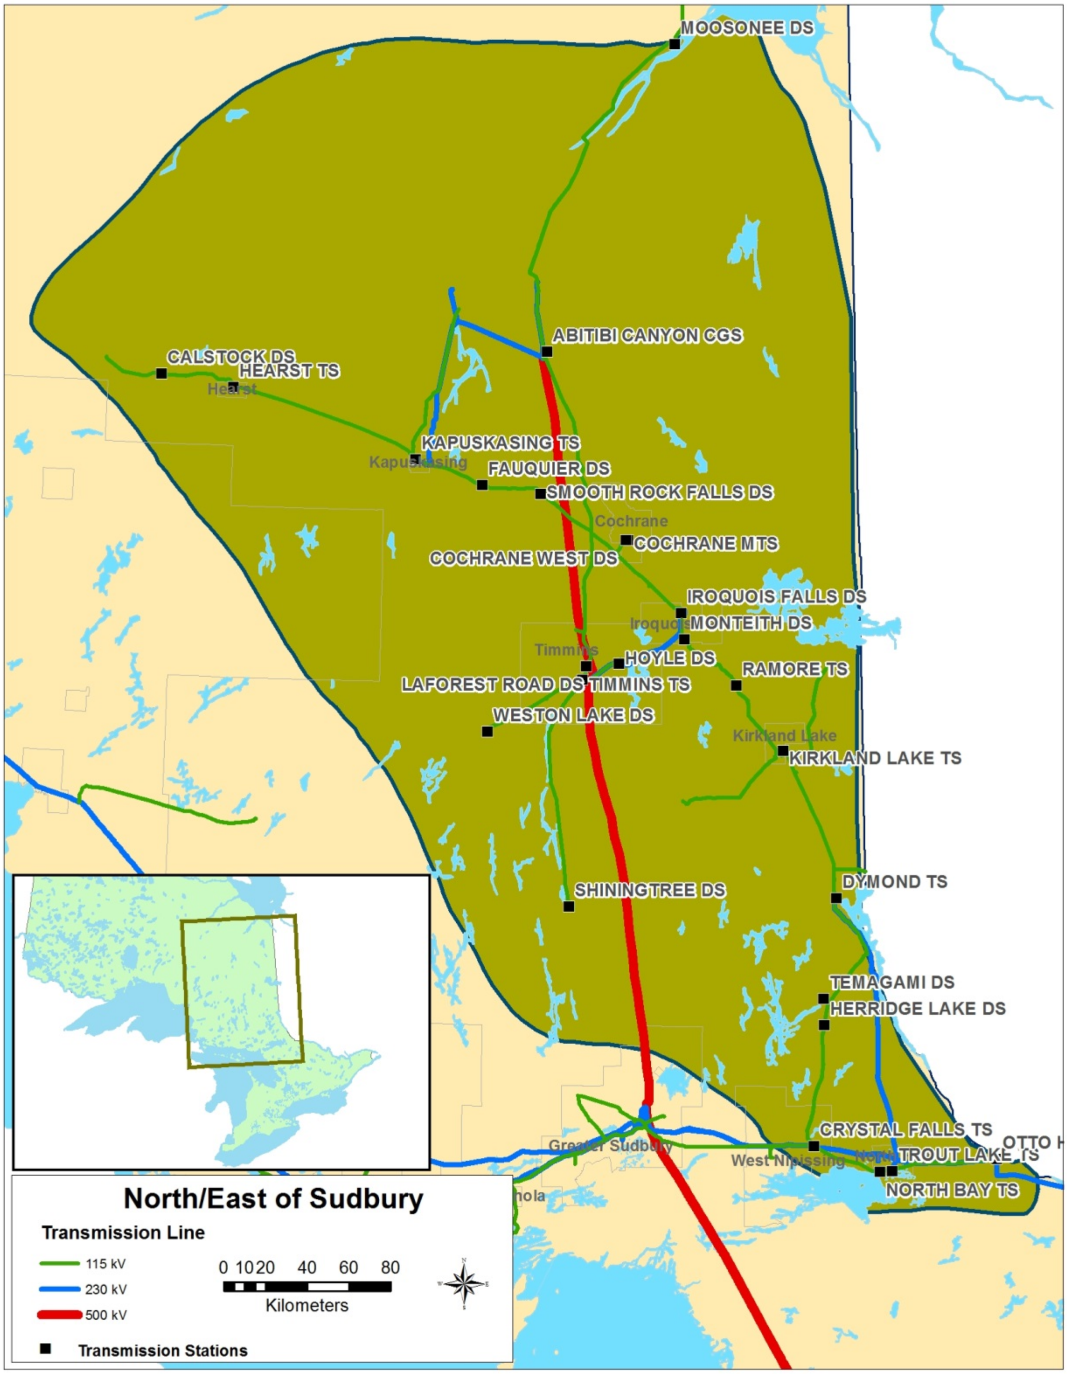

Figure 1: North & East of Sudbury Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. This area is further reinforced through the 500kV circuits P502X and D501P connecting Pinard TS to Hanmer TS.

This region has the following four local distribution companies (LDC):

- Hydro One Networks (distribution)
- Northern Ontario Wires Inc
- Hearst Power Ltd
- North Bay Hydro Distribution Ltd.

115kV circuits	230kV circuits	500kV circuits	Hydro One Transformer Stations

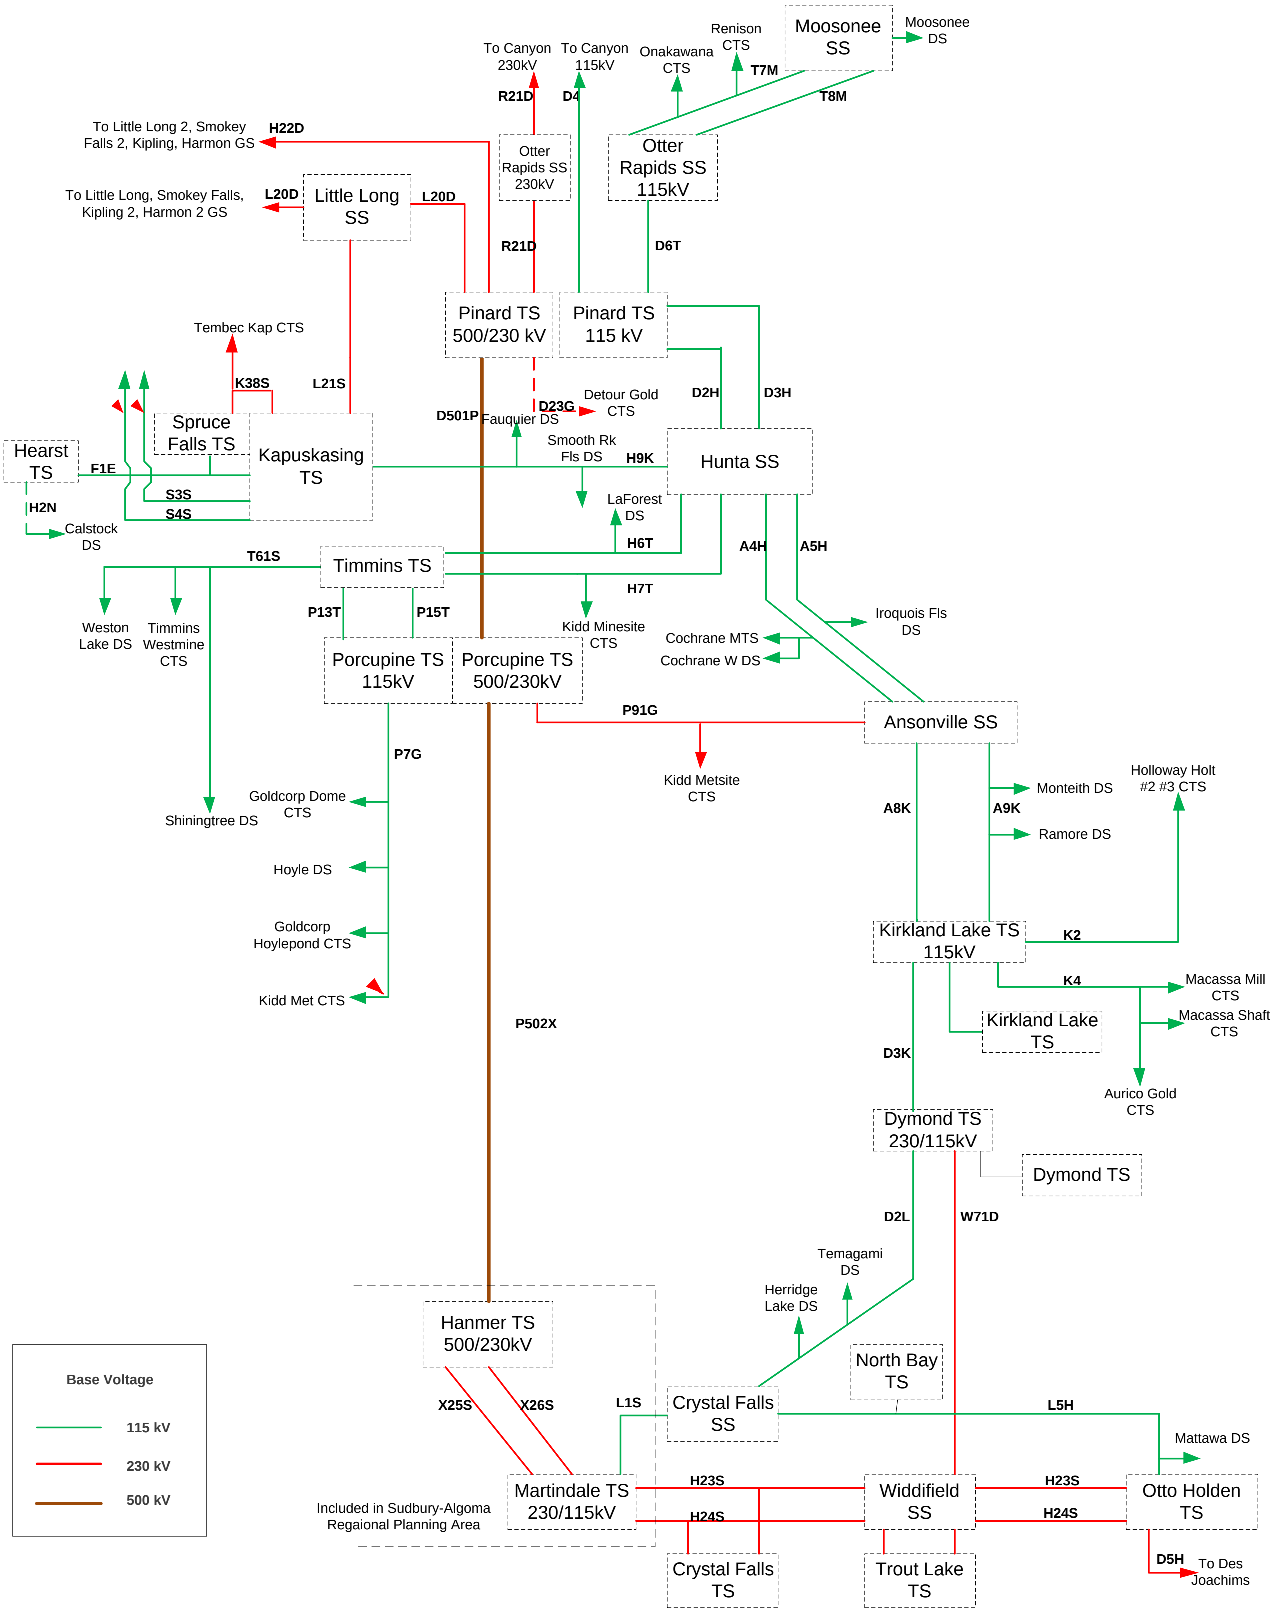

Figure 2 – North and East of Sudbury Regional Planning Electrical Diagram

4 Inputs and Data

In order to conduct this Needs Assessment, Working Group participants provided the following information and data to Hydro One:

- IESO provided:
  - i. Historical Ontario and regional coincident load station peaks, as well as individual station peaks.
  - ii. List of existing reliability and operational issues
  - iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2013-2015) net load and gross load forecast (2016-2026) Note: 2026 gross load values were extrapolated from 2025 if required.
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

Load Forecast
As per the data provided by the Working Group, the gross load in region is expected to grow at an average rate of approximately 0.7% annually from 2016-2026.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. With these factors in place, the total regional load is expected to increase at an average rate of approximately 0.04% annually from 2016-2026.
Note: Extreme weather scenario factor at 1.057 assessed over the study term.

5 Needs Assessment Methodology

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is winter peaking so this assessment is based on winter peak loads.
2. Forecast loads are provided by the Region's LDCs
3. Load data was provided by industrial customers in the region. Where data was not provided, the load was assumed to be consistent with historical loads.
4. Accounting for (2), (3) above, the gross load forecast and net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG are analyzed to determine if needs can be deferred. A gross and net non-coincident peak load forecast was used to perform the analysis for this report. A gross and net region-coincident peak load forecast was used to perform the analysis.

5. Review impact of any on-going and/or planned development projects in the Region during the study period.
6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the winter 10-Day Limited Time Rating (LTR). Summer LTR ratings also were reviewed against the station load forecasts over the study period.
8. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
9. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. Note: This criterion was put in place after the 500 kV Northeast system was built and as such, the system was not originally designed to respect this criteria for the loss of the 500 kV circuits P502X or D501P. Currently the loss of either these circuits can result in the loss of more than 150 MW.
    - With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With up to two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 RESULTS

6.1 500/230kV Autotransfomers
The 500/230 kV transformers supplying the region are adequate for loss of single 500/230 kV unit.

6.2 500/115kV Autotransfomers
The 500/115kV transformers supplying the region are adequate for loss of single unit.

6.3 230/115kV Autotransfomers
The 230/115kV transformers supplying the region are adequate for loss of single unit.

6.4 Transmission Lines and Ratings
The 500kV and 230 kV circuits supplying the region are adequate over the study period for the loss of a single 500kV or 230 kV circuit in the Region.
As per section 7.2 below – the 115kV H9K circuit may experience thermal overloads and will be addressed as a bulk system issue outside of regional planning.

6.5 230 kV and 115 kV Connection Facilities
A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station winter peak load forecast provided by the Working Group. All stations in the area have adequate supply capacity for the study period even in the event of extreme weather scenario

7 SYSTEM RELIABILITY, OPERATION AND RESTORATION

7.1 Performance
The areas of Timmins, Dymond and Abitibi Canyon have experienced severe weather patterns over the last 5 years causing periodic increases of both momentary and sustained outages which have been highlighted by the IESO. The region (including the three mentioned above) does not have circuit performance outliers which would fall below customer delivery point performance standards set forth by the Ontario Energy Board.

Hydro One continually monitors performance of supply stations, and high voltage circuits and will make the necessary steps to address the problem should this issue persist.

7.2 Restoration
Depending on system conditions, the loss of P502X may result in the greatest amount of load lost through North East LR/GR special protection schemes. Based on the load levels in the study period of this assessment, load can be restored within the 30 minute, 4 hour and 8 hour time frames as required by IESO ORTAC Section 7.0. The maximum load which may be interrupted by configuration or load rejection due to the loss of two elements is up to 450MW which is below the ORTAC requirement of 600MW. (loss of P502X with D3K out of service, or vice versa)

7.3 Thermal overloading on H9K section

Under high generation scenarios, IESO has identified pre and post contingency overloads on the 115 kV circuit H9K between *Tembec SRF x H9K 127A* junction.
This is a bulk system issue which will be addressed outside of the scope of regional planning.

7.4 Congestion on D3K, A8K, A9K, H6T and H7T

Under high generation scenarios, IESO has identified there may be congestion on D3K, A8K, A9K, H6T and H7T circuits.
This is a bulk system issue which will be addressed outside of the scope of regional planning.

7.5 Kapuskasing and Calstock Area Generation

Non-utility Generator ("NUG") contracts are reaching end of term for the Kapuskasing and Calstock Generating Stations. The NUG Framework Assessment Report [1] indicated that local reliability and congestion issues may require further study as this pertains to contracted generation facilities. This is a bulk system issue which will be addressed outside of the scope of regional planning.

7.6 Outage Condition Resulting in P15/P7G/T61S radially connected to Timmins

The loss of K1K4 and K1K2 circuit breakers at Porcupine TS can result in excessive voltage declines at Timmins TS 115kV bus.
This scenario will be addressed in the next stage of regional planning.

7.7 Ansonville T2 or D3K outages

With Ansonville T2 or D3K out of service, the loss of the other can result in excessive voltage decline at Kirkland Lake TS. This scenario will be addressed in the next stage of regional planning.

8 AGING INFRASTRUCTURE AND REPLACEMENT OF MAJOR EQUIPMENT

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables. during the study period. At this time the major committed system investments are;

Dymond TS (T3/T4) transformers (2016)
Kirkland Lake TS (T12/T13) transformers (2017)
Timmins TS (T63/T64) with single 83MVA (2016)
Otto Holden TS (T3/T4) autotransformers, and 115kV circuit breakers (2019)

9 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, it is further recommended that voltage regulation issues at Timmins TS and Kirkland Lake TS be best addressed by wires options solution thru local planning led by Hydro One:

10 NEXT STEPS

Based on the findings of the Needs Assessment, the Working Group recommends that no further regional coordination is required and the two voltage regulation needs identified in Section 7 be further assessed as part of Local Planning to be entitled:

<u>Timmins TS / Kirkland Lake TS – Voltage Regulation Issues</u>

Renfrew Region

Regional Infrastructure Plan ("RIP")

July 22nd, 2016

Independent Electricity System Operator
Renfrew Hydro Inc.
Ottawa River Power Corporation
Hydro One Networks Inc. (Distribution)

The Renfrew Region consists of Renfrew County and it is roughly bounded by the Des Joachims TS on the West and Chenaux TS on the East, and 230kV circuit X1P to the Southeast.

The Needs Assessment ("NA") report for the Renfrew region was completed in March, 2016 (see attached). The report concluded that no regional planning needs were identified for the region at this time although circuit X1P is nearing its capacity and will be monitored on a regular basis over the next three to five years.

There are no other major development projects planned for the Renfrew Region over the near and mid-term.

Consistent with a process established by an industry working group[1] created by the OEB, the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no regional planning was required, this letter and the attached NA report will be deemed to form the ("RIP") for the Renfrew Region.

The next regional planning cycle for the region is expected to be undertaken in five years from the start of this planning cycle (2015) or earlier if there is a new need emerging in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Renfrew Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Renfrew Region (the Region)		
LEAD	Hydro One Networks Inc. (Hydro One)		
START DATE	October 23, 2015	**END DATE**	March 11, 2016

1. INTRODUCTION

The purpose of this Needs Assessment report is to undertake an assessment of the Renfrew Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE/ TRIGGER

The Needs Assessment for the Renfrew Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups - Group 1 Regions are being reviewed first. The Renfrew Region belongs to Group 3. The Needs Assessment for this Region was triggered on October 23, 2015 and was completed on March 11, 2016.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this Needs Assessment was limited to the next 10 years as per the recommendations of the Planning Process Working Group Report to the Board.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led Scoping Assessment and/or IRRP, or in the next planning cycle to develop a 20-year IRRP with strategic direction for the Region.

The assessment included a review of transmission system connection facilities capability, which covers station loading, thermal, and voltage analysis, system reliability, and assets approaching end-of--life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One transmission provided information for the Renfrew Region. The information included: existing information from planning activities already underway, historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-life.

5. ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs in the Region over the study period (2015 to 2024). The assessment reviewed available information and load forecasts and included single contingency analysis to identify needs.

6. RESULTS

Transmission Capacity Needs

A. Station Capacities

- All stations in the region have sufficient capacity to supply the loads in studied period under normal and single contingency condition.

B. Transmission Circuits Capacities

- All transmission circuits have sufficient capacity under normal and single contingency condition.

System Reliability, Operation and Restoration Needs

There are no transmission system reliability issues and no operating issues identified for one element out of service in this Region.

Based on the gross coincident demand forecast, loss of one element will not result in load interruption for more than 150MW by configuration.

All load within the region can typically be restored within eight hours as per the ORTAC requirement for loads under 150 MW.

In recent years, maintenance activity in the region with respect to vegetation management has been enhanced resulting in an improvement in reliability and/or load restoration.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace aged equipment at three stations will increase station capacities. Further details of these investments can be found in Section 3.2 of this report.

7. RECOMMENDATIONS

Based on the findings of this Needs Assessment, the study team's recommendations are as follows:

- Should the performance of X1P fall below adequate levels (as shown by standard OGCC monitoring systems) the Hydro One will undertake to assess and address this issue with the LDCs.

- No further coordinated regional planning is required for this region at this time. The next regional planning cycle for the region is expected to be undertaken in Q1 2019 or earlier if there is a new need emerging in the region.

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1 INTRODUCTION

This Needs Assessment report provides a description of the analysis to identify needs that may be emerging in the Renfrew Region (the Region) over the next ten years. The development of the Needs Assessment report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this Needs Assessment report is to: consider the information from planning activities already underway; undertake an assessment of the Renfrew Region to identify near term and/or emerging needs in the area; and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with LDCs or other connecting customer(s) will further undertake planning assessments to develop options and recommend solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (the IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required.

This report was prepared by Hydro One (Lead Transmitter) with input from the Renfrew Region Needs Assessment study team. The report captures the results of the assessment based on information provided by LDCs and the IESO.

2 TRIGGER OF NEEDS SCREEN

The Needs Assessment for the Renfrew Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, where Group 1 Regions are being reviewed first. The Region falls into Group 3. The Needs Assessment for this Region was triggered on October 23, 2015 and was completed on March 4, 2016.

3 SCOPE OF NEEDS ASSESSMENT

This Needs Assessment covers the Renfrew Region over an assessment period of 2015 to 2024. The scope of the Needs Assessment includes a review of transmission system connection facility capability which covers transformer station capacity, transmission circuits thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

3.1 Renfrew Region Description and Connection Configuration

The Renfrew Region includes all of Renfrew County. Fig.1 shows the map of the Region. The 2014 peak load in this Region was 124 MW.

The electricity supply to the region is mainly through one 230kV circuit X1P and three 115 kV radial circuits: D6, X6 and X2Y (Fig.1). The 115kV circuits are supplied by 230/115 kV autotransformers at Chenaux Transformer Station (TS) from the East and Des Joachims TS from the West. A normally opened 115kV switch at Pembroke TS isolates the East and the West sides of the region.

The Renfrew Region is roughly bounded by the Des Joachims TS on the West and Chenaux TS on the East, and 230kV circuit X1P to the Southeast. The distribution system in this region consists of voltage levels 44 kV, 13.8 kV, and 12.5 kV. The main generation facilities in the Renfrew Region are Chenaux Generation Station (GS) of 143.7 MW (according to Transmission Connection Agreement, applicable thereafter), Mount Chute GS of 170.2 MW and Des Joachims GS of 432.5 MW.

Hydro One Networks Inc. (Distribution) is the main customer in the area. Other Local Distribution Companies (LDC) supplied from electrical facilities in the Renfrew Region includes Ottawa River Power Corporation and Renfrew Hydro Inc, both are embedded into Hydro One's distribution system. Major transmission connected customers in the area include Canadian Nuclear Laboratories and Magellan Aerospace.

.

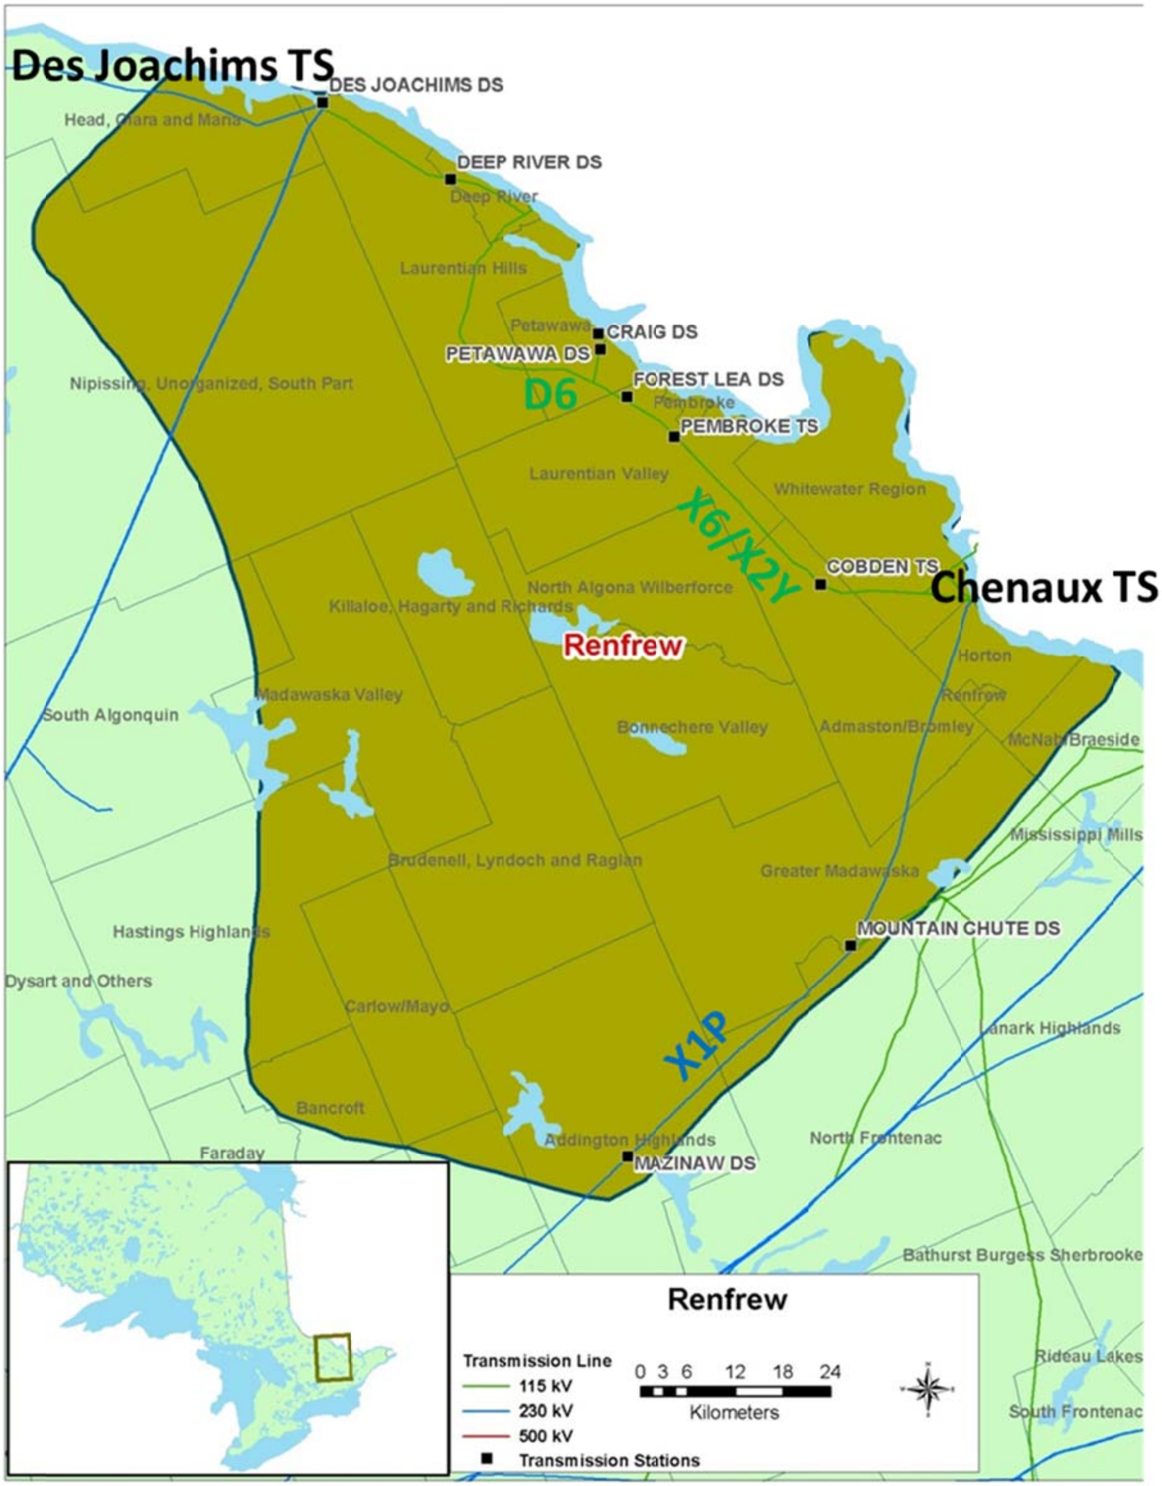

Fig. 1 Renfrew Region Map

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Fig. 2.

- Des Chenaux TS is a major 230kV station in the region. The station has 143.7MW of hydraulic generation connected to the 230kV bus. The station connects to the bulk system via a single 230kV circuit X1P. Two autotransformers step down the voltage to 115kV to supply two radial circuits X6 and X2Y.

- The 115kV circuits X6 and X2Y from Chenaux TS supply four stations: Pembroke TS, Cobden TS, Cobden DS and Magellan Aerospace CTS. The two circuits are coupled via and only via Pembroke 44kV bus tie breaker

- Des Joachim TS is the other major 230kV transformer station in the Region. There are 432.5MW of hydraulic generation units connecting to the 230kV bus. The station interconnects to the Bulk Electric System (BES) via five 230kV circuits which are not in the scope of this regional assessment. Two autotransformers (one operates as standby) step down the voltage to 115kV to supply one radial circuit D6.

- The 115kV circuit D6 from Des Joachim TS 115kV bus supplies six stations: Des Joachims Distribution Station (DS), Deep River DS, Craig DS, Forest Lea DS, Petawawa DS, and Chalk River Customer Transformer Station (CTS).

- All the 115kV circuits X6/X2Y/D6, all the 115kV stations tapped to the 115kV circuits, and all the autotransformers at Des Joachims TS and Chenaux TS are not NERC BES element.

- Bryson GS of Hydro Quebec can be radially connected to Renfrew region via X2Y.

- The 230kV single circuit X1P from Dobbin TS to Chenaux TS connects two stations in Renfrew Region: Mountain Chute GS (with hydraulic generation of 170.2MW) and Mazinaw DS.

- Mountain Chute DS, a 115kV station adjacent to Mountain Chute GS, is supplied by a circuit W3B from outside of the studied region. The DS typically has load less than 1MW.

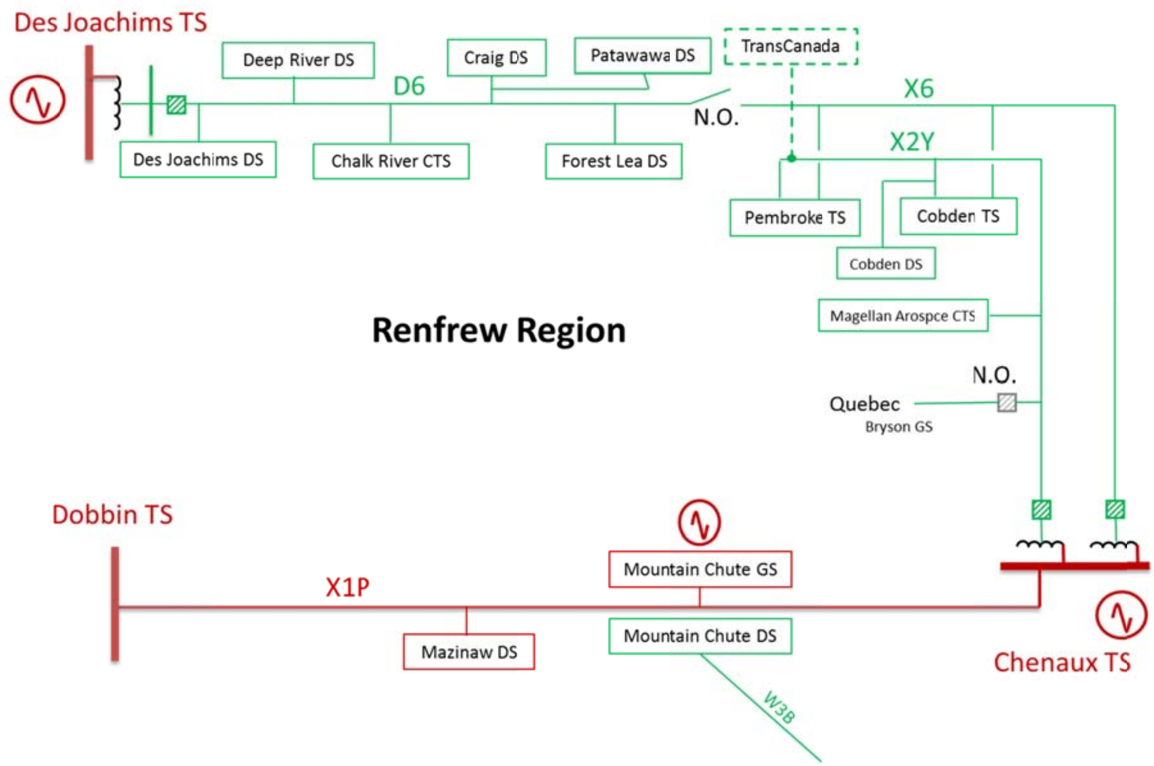

Fig. 2 Single Line Diagram – Renfrew Region

3.2 Planned Work in Renfrew Region

Following work has been planned in Renfrew Region:

- Two step-down transformers at Deep River DS (T1 and T2) will be replaced due to end-of-life for an in service date of end of 2016. This will also result in uprating the transformer capacity from 10MVA to 12.5MVA.
- Mountain Chute DS transformer will be replaced due to end-of-life with an in service date of end of 2016. This will also result in uprating the transformer capacity from 3MVA to 12.5MVA.
- Chenaux TS 230/115kV autotransformers T3 and T4 will be replaced due to end-of-life with an in service date of end of 2018. The existing units are rated 78MVA and 115MVA respectively. The new T3/T4 will both have continuous rating of 125MVA. This is a transmission pool investment and LDCs are not expected to pay.
- A TransCanada pump station is expected to tap to X2Y at Pembroke TS (Fig.2). The peak load of the station is 19.4MW. Two capacitor banks, each rated at 10Mvar, are assumed to be in service with the load. The station is expected to be in service in 2020.

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information to Hydro One:

- IESO provided:
  i. Historical regional coincident peak loads and station non-coincident peak loads between 2012 and 2014
  ii. List of existing reliability and operational issues
  iii. Conservation and Demand Management (CDM) and future Distributed Generation (DG) data
- LDCs provided historical (2012-2014) net loads and gross loads forecasts (2015-2024) for each station.
- The study team could not get response from Chalk River CTS and Magellan Aerospace CTS regarding their load forecasts. It is assumed that the loads at these two stations would not increase over the study period.
- Any relevant planning information, including planned transmission and distribution investments are provided by the transmitter and LDCs.

As per the data provided by the study team, the net load (i.e. after DG and CDM adjustment) in the Renfrew Region is expected to grow at an average rate of approximately 0.6% annually from 2015 to 2024.

5 ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region typical typically has winter peak. Fig. 3 plots the load profiles at Pembroke TS and Cobden TS from July 2013 to July 2015, which evidences the winter peaking characteristics. Therefore this assessment is based on winter peak load.

2. Loads forecasts are provided by the LDCs, i.e., Hydro One Networks Inc. (Distribution) in this case.

3. Average gross load growth rate at each station is calculated from the LDC's load forecast. The growth rates are then applied to the 2014 coincidental winter peak load to generate each year's coincidental peak load.

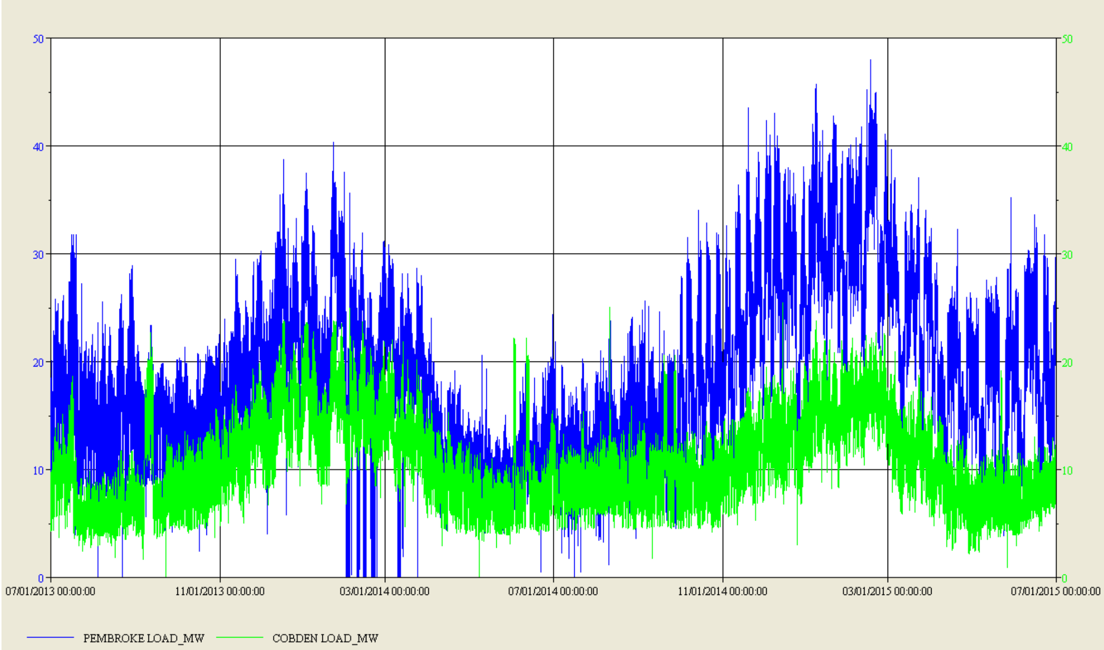

Fig. 3 Pembroke TS and Cobden TS Winter Peak Load Profiles

4. The 2014/15 winter was already extremely cold; therefore no extreme weather adjustment was used.

5. The gross demand forecast is used to develop a worst case scenario to identify needs. Both the gross demand forecast and the net demand forecast (which includes forecasted CDM and DG contributions) were used to determine the timing of the needs.

6. Review impact of any on-going and planned development projects in the Region during the study period. This includes:

    - A new 19.4MW load is expected to connect to circuit X2Y at Pembroke in 2020. This Needs Assessment assumes that the load is in service.

7. Review and assess impact of any major elements planned to be replaced at the end of their useful life such as transformers, cables, and stations.

8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity by assuming a 90% lagging power factor for stations without low-voltage capacitor banks and 95% lagging power factor for stations with low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this Region is determined by the 10-Day Limited Time Rating (LTR).

9. To identify emerging needs in the Region and determine whether further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.

10. Transmission adequacy assessment is primarily based on the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range. Projected coincidental peak loads are used in such assessment.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer 10-Day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC). Des Joachims and Chenaux 115kV bus voltages are maintained between 122kV and 127kV according to established operation practice.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - The system is capable of meeting the load restoration time limits as per ORTAC criteria.

11. Full load transfers for restoration purposes are not mandatory requirement. Restorations of load between Chenaux TS and Des Joachims TS via D6-X6 load transfers are performed to the extent possible.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Renfrew Region.

6.1 Transmission Capacity Needs

This is to assess a) adequacy of each station's load supply capacity which is mainly to inspect the step-down transformer ratings; and b) adequacy of transmission facility to deliver the power within the Region under normal and contingency conditions, which is mainly determined by circuit thermal rating and voltage profile.

6.1.1 Station Adequacy Assessment

Non-coincident peak load at each station is compared against corresponding transformer maximum continuous rating or 10-day LTR if the continuous rating is exceeded. The peak loads are all forecasted to happen in 2024. Table 2 compares the net peak load against transformer ratings at each station. It can be seen that all stations are adequate to supply the loads in studied period.

Table 2 Station Adequacy Assessment

Station	Transformers	Net Peak Load (MW)	Transformer Rating/LTR* (MW)
Cobden DS	T3	7.2	11.3
Cobden TS	T1/T2	27.1	37.5
Craig DS	T1/T2	12.2	15.9
Deep River DS	T1/T2/T3	11.1	23.8
Des Joachims DS	T1	3.3	11.3
Forest Lea DS	T1/T2	9.2	9.9
Mazinaw DS	T1	3.4	5.4
Mountain Chute DS	T1	1.0	11.3
Pembroke TS	T1/T2	49.1	49.6
Petawawa DS	T1/T2	14.3	14.8
Chalk River CTS***		10	N/A
Magellan Aerospace CTS***		3.1	N/A
Chenaux TS	T3/T4	101.7**	112.5
Des Joachims TS	T6/T7	57.1	112.5

*: LTR is listed only if the peak load exceeded transformer continuous rating
**: Including 19.4MW new load, all station MVAs add up arithmetically
***: Load customer owned transformers, capacity not assessed in this study

6.1.2 Transmission Facility Adequacy Assessment

Under normal condition with all elements in service and the D6-X6 in-line switch open, the study found that:

- All transmission circuits supplying the Region, namely D6, X6, X2Y and X1P have adequate capacity over the study period.

The projected regional peak loads can be supplied even if the local generations at Des Joachims GS and Chenaux GS are out of service. In the X6/X2Y corridor, loss of one circuit (including breaker failure condition to cause additional loss of Chenaux generation) would not cause overload or under-voltage on the accompanying circuit. .

6.2 System Reliability, Operation and Restoration Review

- The Region’s total coincidental peak load is less than 150MW, therefore load loss violation due to configuration does not apply in this assessment.
- All loads are expected to be restored within 8 hours.
- The most critical contingency in the Region would be loss of 230kV circuit X1P which would produce an island at Chenaux. Stable islanding operation might be

achieved depending on pre-contingency flow and generation rejection arming. Reliability data recorded 13 X1P non-planned outages in past ten years, among which seven events show stable islanding operations before the system was paralleled back to the grid. In another two events the island collapsed after more than one hour of operation. The performance is expected to be unchanged in the study period.

- Studies show that under this contingency, Des Joachims TS may not be able to radially supply all the loads in the Region, under peak load conditions.
- Due to the fact that the loads are supplied via radial circuits and the Region is prone to storms, extended outages on D6 were experienced in the past (in 2011 for example). Further, outage analysis indicated that the most common cause for sustained outages was under severe storm. This issue cannot be addressed by building additional line in the same right-of-way. As a result, improved vegetation management and outage responses have effectively reduced sustained outages considerably in recent years. Table 3 lists sustained outage records of D6 in past five years.

Table 3 Outage Records of D6 from 2011 to 2015

Year	No. of Sustained Outages	Cumulative Duration (min)	Causes
2015	1	367	Conductor Broken
2014	1	5	Human Error
2013	3	1381	Isolated Electrical Storm
2012	1	1341	Tree Contact
2011	4	7792	Tree Contact

Studies show that under D6 terminal outage at the Des Joachims terminal, load can be restored by transferring D6 to Chenaux TS 115kV via X6 supply. Note, there is a maximum limit of 125 MW, which is the peak regional load in 2015, that can be supplied radially from Chenaux.

a) The following potential needs will be monitored and assessed in the next Regional Planning cycle for the Renfrew Region:

- Hydro One and the LDCs will continue to monitor and assess the load restoration performance under X1P and D6 outages.

- Major Hydro One facilities and equipment are continually monitored to ensure their safe and reliable operation. Circuit X1P is one of these facilities and, as such, its performance is monitored by Hydro One's Ontario Grid Control Centre (OGCC) in Barrie. OGCC's records will be reviewed regularly to ascertain the adequate performance of this circuit. The next planning cycle will take place in five years however, if the performance of X1P fall below adequate levels the Hydro One will undertake to assess and address this issue with the LDCs.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Section 3.2 lists the sustainment initiatives that are currently planned for the replacement of any aged transformers. There are no major line replacement plans scheduled in the near term in this region.

7 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team's recommendations are as follows:

No further coordinated regional planning is required for this region at this time. The next regional planning cycle for the region is expected to be undertaken in Q1 2019 or earlier if there is a new need emerging in the region. Should the performance of X1P fall below adequate levels (as shown by standard OGCC monitoring systems) the Hydro One will undertake to assess and address this issue with the LDCs.

St. Lawrence Region

Regional Infrastructure Plan ("RIP")

July 22nd, 2016

Independent Electricity System Operator
Hydro One Networks Inc. (Distribution)

The St Lawrence Region covers the southeastern part of Ontario bordering the St Lawrence River. The region starts at the Gananoque in the West and extends to the inter-provincial boundary with Quebec in the East..

The Needs Assessment ("NA") report for the St. Lawrence region was completed in April, 2016 (see attached). The report concluded that no regional planning needs were identified for the region at this time.

There are no other major development projects planned for the ST. Lawrence Region over the near and mid-term.

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no regional planning was required, this letter and the attached NA report will be deemed to form the ("RIP") for the St. Lawrence Region.

The next regional planning cycle for the region is expected to be undertaken in five years form the start of this planning cycle (2015) or earlier if new needs emerge in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

NEEDS ASSESSMENT REPORT

Region: St Lawrence

Date: April 29, 2016

Prepared by St Lawrence Region Study Team

St Lawrence Region Study Team

Company
Hydro One Networks Inc. (Lead Transmitter)
Independent Electricity System Operator
Hydro One Networks Inc. (Distribution)

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the St Lawrence region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	St Lawrence (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	March 1, 2016	**END DATE**	April 29, 2016

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the St Lawrence Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the St Lawrence Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 regions is complete and has been initiated for Group 3. The St Lawrence Region belongs to Group 3. The NA for this Region was triggered on March 1, 2016 and was completed on April 29, 2016.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2025. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the Independent Electricity System Operator (IESO) and Hydro One transmission provided information for the St Lawrence Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2016 to 2025). The assessment reviewed available information, load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Needs

A. 230/115 kV Autotransformers

The 230/115kV Autotransformers at St Lawrence TS are adequate over the study period for the loss of a single 230/115kV unit

B. Transmission Lines & Ratings

The 230kV lines are adequate over the study period. A Special Protection Scheme is in place to reject generation at Beauharnois GS and/or Saunders GS under post contingency conditions to ensure the loading on the St Lawrence to Hinchinbrooke TS 230KV circuits are within ratings.

The 115kV lines are adequate over the study period to supply the forecasted load. The section of the 115kV lines L2M/L1MB between St Lawrence TS and Lunenberg Jct may be overloaded under light load conditions and high DG and Cardinal Power generation, for the loss of the companion circuit. Since 2012, Morrisburg TS has been restricted and no additional generation is accepted. At the same time, this situation is also mitigated using the Cardinal Power CGS run back scheme or by limiting generation dispatch during these light load conditions. No further action is required.

C. 230 kV and 115 kV Connection Facilities

The 230kV and 115kV connection facilities in this region are adequate over the study period.

Inadvertent breaker operation (IBO) at Cardinal Power on either L1MB or L2M can result in Morrisburg TS transformers exceeding their reverse flow limits and/or cause a transformer to be loaded beyond ratings at Dyno Nobel CTS. Morrisburg TS has been restricted and no additional generation is accepted since 2012. This situation is also mitigated by using Cardinal Power runback scheme. No further action is required.

System Reliability, Operation and Restoration Review

Based on the gross coincident load forecast, the loss of one element does not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period. No action is required.

Chesterville TS missed its delivery point performance standard in recent years due to momentary outages resulting from severe weather patterns. The delivery point performance at Chesterville TS will be assessed and monitored to determine if corrective actions are required. No further action is required as part of regional planning.

Aging Infrastructure / Replacement Plan

Within the regional planning time horizon, the following sustainment work is currently planned by Hydro One in the region:

- Morrisburg TS: components replacement (2019 in service)
- Smiths Falls TS: components replacement (2021 in service)
- St Lawrence TS: components replacement (2024 in service)

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that no further regional coordination or further planning is required. The region will be reassessed within five years as part of the next planning cycle.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the St Lawrence Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the St Lawrence Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs if straight forward wires solutions can address a need. Ultimately, assessment and findings of the local plans are incorporated in the RIP for the region.

This report was prepared by the St Lawrence Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

2 REGIONAL ISSUE / TRIGGER

The NA for the St Lawrence Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The St Lawrence Region belongs to Group 3.

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the St Lawrence Region over an assessment period of 2016 to 2025. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

St Lawrence Region Description and Connection Configuration

The St Lawrence Region covers the southeastern part of Ontario bordering the St Lawrence River. The region starts at the Gananoque in the West and extends to the inter-provincial boundary with Quebec in the East.

The western part of the region is supplied from Hydro One owned stations connected to the 230kV network. The reminder of the region is supplied from Hydro One stations connected to the 115kV network except for St Lawrence TS which is supplied from 230kV.

The City of Cornwall is supplied by Fortis Ontario with transmission lines from Quebec and is not included in this Region. A map of the region is shown below in Figure 1.

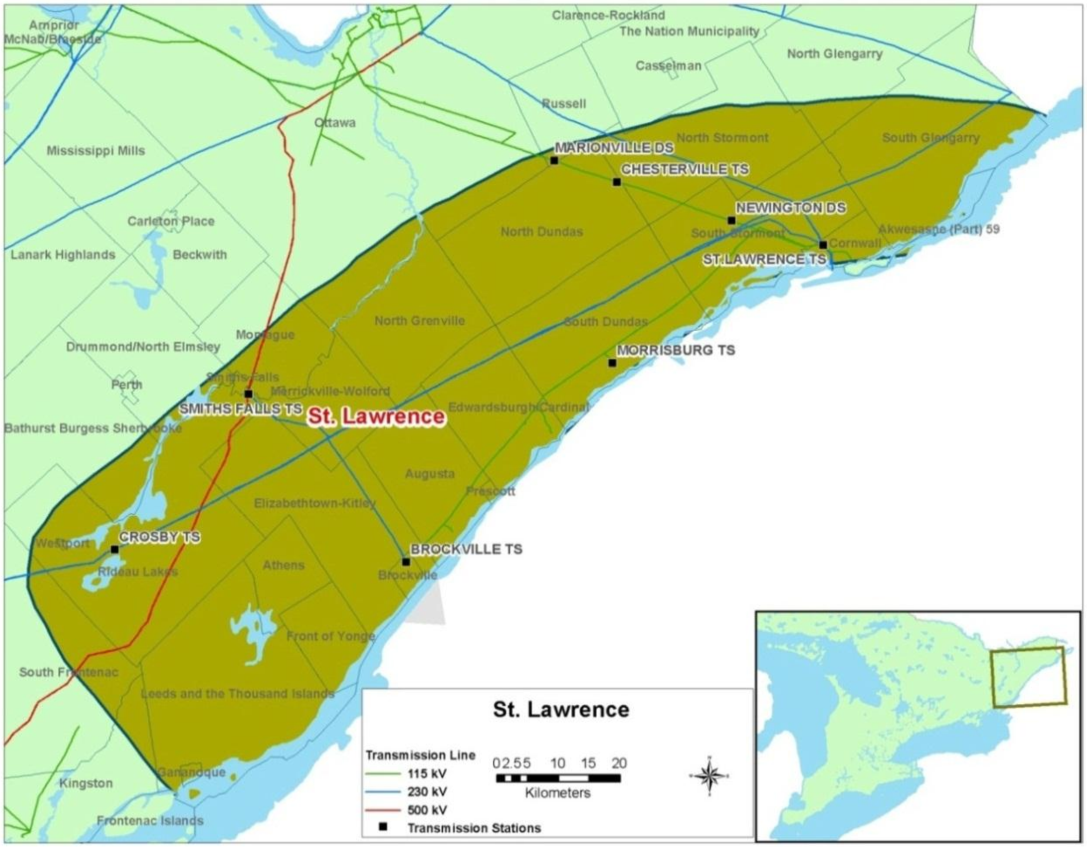

Figure 1 Map of St Lawrence Regional Planning Area

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. The major source of supply for this region is OPG's Saunder Hydro Electric station which connects to St Lawrence TS 230kV yard.

This region has the following three local distribution companies (LDC):

- Hydro One Networks (Distribution)
- Cooperative Hydro Embrun Inc. (embedded in Hydro One Distribution)
- Rideau St Lawrence Distribution Inc. (embedded in Hydro One Distribution)

Table 2 Transmission Lines in the St Lawrence Region

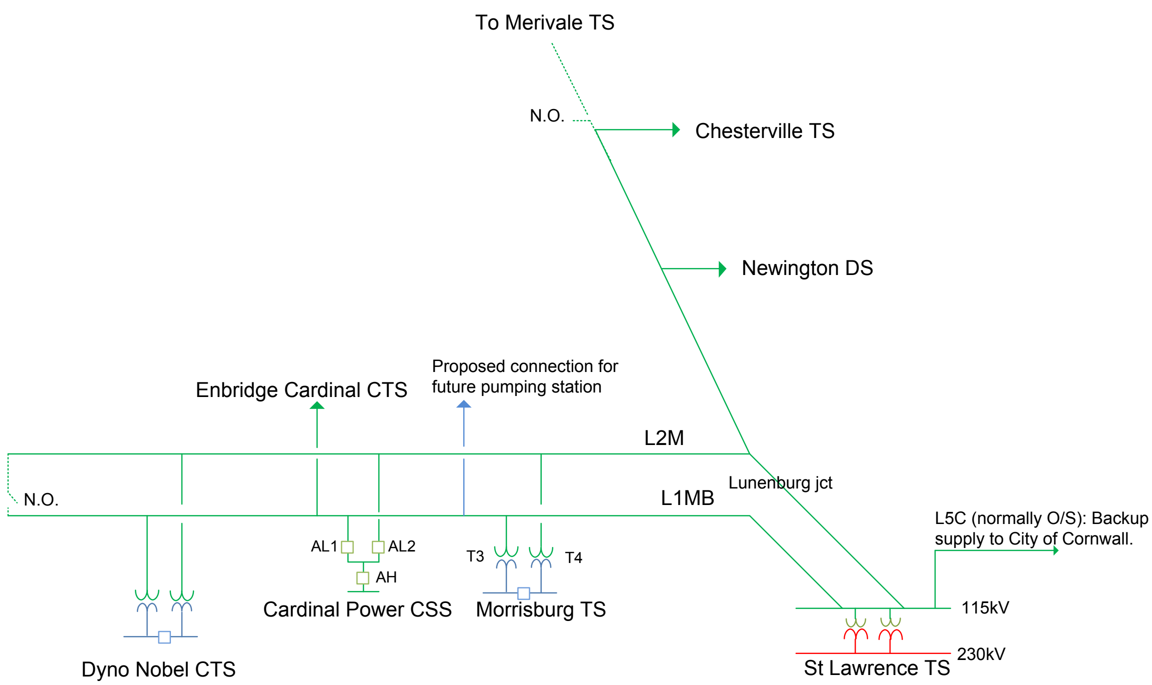

Figure 3 Single Line Diagram 115 kV St Lawrence Regional Planning Area

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
  - i. Historical Ontario and regional coincident load station peaks, as well as individual station peaks.
  - ii. List of existing reliability and operational issues
  - iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2013-2015) net load and gross load forecast (2016-2025).
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

Load Forecast

As per the data provided by the study team, the gross load in region is expected to grow at an average rate of approximately 0.8% annually from 2016-2025.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. With these factors in place, the total regional load is expected to increase at an average rate of approximately 0.2% annually from 2016-2025.

Future Project

As shown in Figure 3, there is a proposal to connect a pumping station for the TransCanada Energy East project that will add 18MW of load to the area. The pumping station is planned to be connected to circuit L1MB close to Morrisburg TS. The current in-service date is 2021.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is winter peaking so this assessment is based on winter peak loads.
2. Saunders GS was assumed to generate at its average 98% of time dependable hydro generation level which is 542MW.
3. Forecast loads are provided by the Region's LDCs

4. Load data was requested from industrial customers in the region. Where data was not provided, the load was assumed to be consistent with historical loads.
5. Accounting for (3), (4), above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to verify each station is within its rating to supply the forecasted load. The net forecast was used for system study.
6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the winter 10-Day Limited Time Rating (LTR). Winter LTR ratings were reviewed.
8. Extreme weather scenario factor at 1.0582 was also assessed for capacity planning over the study term.
9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their winter long-term emergency (LTE) ratings. Thermal limits for transformers are acceptable using winter loading with winter 10-day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 RESULTS

230/115 kV Autotransformers
The 230/115kV Autotransformers at St Lawrence TS are adequate over the study period for the loss of a single 230/115kV unit

Transmission Lines & Ratings

230kV Lines
The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

There is a generation rejection scheme in place that can runback Saunders GS and/or Beauharnois GS under post-contingency conditions. This scheme ensures that the St Lawrence to Hinchinbrooke TS lines are not overloaded under peak summer conditions.

115kV Lines
Under the assumptions made for regional planning, the 115kV lines are adequate over the study period for the loss of a single circuit in the Region.

The following operating issues have been previously in the SIA/CIA done for Cardinal Power G3 Expansion [4, 5]:

Under light load condition and with all distributed generation in the area and the Cardinal Power generation at maximum output the section of the L1MB/L2M line between St Lawrence to Lunenburg JCT can be loaded beyond its short time emergency (STE) rating for loss of either circuit.

To manage the situation, Morrisburg TS has been restricted to accept new generation connection since 2012. In addition, there is Cardinal Power's runback scheme will reduce the plant output following the loss of either circuit and hence reduce the post-contingency loading on either of the L1MB/L2M lines. However since the lines could be loaded beyond their STE, measures such generation re-dispatch is implemented by the IESO as per the Cardinal Power G3 Expansion studies [4, 5].

230 kV and 115 kV Connection Facilities
A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station winter peak load forecast provided by the study team. All stations in the area have adequate supply capacity for the study period even in the event of extreme weather scenario.

Reverse Power Flow

At Morrisburg TS, under light load condition and high distributed and directly connected generation, a reverse power flow issue was identified in the Cardinal Power G3 Expansion SIA/CIA [4, 5]. This situation occurs if one of the line breakers at Cardinal Power has an inadvertent opening (IBO). This IBO results in all of Cardinal Power's generation being sent to one line, which causes reverse power at Morrisburg TS beyond its maximum limit. As noted previously, since 2012, additional generation connection has been restricted at Morrisburg TS to manage the reverse power flow at the station.

Dyno Nobel CTS

Under the same conditions mentioned above, an IBO at Cardinal Power can also result in power flow through the Dyno Nobel CTS to exceed their rating [4, 5].

For Morrisburg TS and Dyno Nobel CTS transformer loading issues, Cardinal Power run back scheme is triggered to reduce the flows to within equipment ratings as it was outlined in the SIA and CIA [4,5]. No further action is recommended within the scope of this regional planning.

7 SYSTEM RELIABILITY, OPERATION AND RESTORATION

Based on the gross coincident load forecast, the loss of one element does not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW for the duration of the 10-year study period.

Chesterville TS and Newington DS are on single supply from L2M for a combined gross load of 50MW in 2025. If the supply from St Lawrence TS becomes unavailable, these two stations can be supplied from Merivale TS.

All loads in the St Lawrence area can be restored within the 8 hour requirement.

IESO indicated in their unsupplied energy report that the 115kV area did not meet its target in the past. Chesterville TS missed its customer delivery point target (frequency of interruption) in recent years due to momentary outages seen as a result of severe weather patterns. Hydro One will review and monitor its supply point performance at Chesterville TS to determine if corrective measures are required. No further actions required as part of regional planning.

8 AGING INFRASTRUCTURE AND REPLACEMENT PLAN OF MAJOR EQUIPMENT

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables during the study period. At this time the following sustainment work is planned for the stations in the area:

Morrisburg TS: Protection upgrade, 44kV breakers (2019 in service)

Smiths Falls TS: Protection replacement, battery and charger, switches (2021 in service)

St Lawrence TS: Replacement of oil breakers at 230kV, 115k, and 44kV; replacement of AC/DC station service supplies; and protection upgrade work. (2024 in service)

The facilities at these stations are adequate and there is no need to increase the equipment rating.

9 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that no further regional coordination or further planning is required. The region will be reassessed within five years as part of the next planning cycle.

10 NEXT STEPS

No further Regional Planning is required at this time. The St Lawrence Region Regional Planning will be reassessed during the next planning cycle or at any time should unforeseen conditions or needs warrant to initiate the regional planning for the region.

SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
ULTC	Under Load Tap Changer

1.3 (5.2.2) CUSTOMER ENGAGEMENT – HOW HYDRO ONE'S INVESTMENT PLAN INCORPORATES THE NEEDS OF CUSTOMERS

Hydro One's transmission system serves a diverse customer base made up of: (i) electricity generators who deliver power to the transmission system; (ii) distributors who deliver power to direct customers; and (iii) end-users such as mining and industrial enterprises that use the power themselves at transmission level voltage.

Hydro One's customers are located throughout the province. Serving customers in northern and rural areas presents different challenges due to sparse populations, remote location of assets and often, single-phase circuits. Conversely, customers in non-rural, more populated areas often share multi-circuit lines with other transmission customers. Indeed, the three customer groups described above often have needs and preferences unique to their segement. Engaging with these different customer segments requires a number of channels for customer engagement.

Through its broad range of customer engagement activities, Hydro One has developed a clear and specific understanding of the outcomes that its transmission customers care most about, as well as the level of spending and mix of investments that customers would most like to see included in Hydro One's investment plan. The feedback received from customers through these engagement activities is an important and direct input into Hydro One's investment planning process. Consequently, Hydro One's capital expenditure plan, as set out in Section 3 of this Transmission System Plan ("TSP"), is closely aligned with and highly responsive to the customer needs and preferences that Hydro One has identified.

This section describes the various initiatives through which Hydro One has developed an understanding of the specific needs and preferences of customers, including a customer engagement survey that was carried out specifically to inform this TSP. The feedback received from these processes has contributed to Hydro One's understanding of the outcomes that are of the greatest value to its transmission customers. This feedback has been inputted directly into Hydro One's investment planning process. The results of the customer engagement survey have been re-affirmed by feedback received from subsequent ongoing customer engagement activities.

1.3.1 (5.2.2 A) IDENTIFICATION OF CUSTOMER NEEDS AND PREFERENCES

Hydro One collects feedback from transmission customers through the following initiatives:

- Customer Engagement Surveys;
- Large Customer Account Management;
- Ontario Grid Control Centre's ("OGCC") Customer Operating Support Group;
- Large Customer Conferences;
- Oversight Committees and Working Groups;
- Customer Satisfaction Surveys and Research; and
- Focussed Planning Meetings with Customers.

These initiatives are firmly integrated into Hydro One's business practices and are fundamental to the way Hydro One interacts with its customers and carries out its transmission business. The Customer Engagement Survey has been a valuable process for supplementing, formalizing and validating the feedback Hydro One collects through ongoing engagement activities, and for formalizing the manner in which this feedback is integrated into investment planning.

Figure 1 below is a summary of key priorities for customers based on customer engagement and specific steps taken to incorporate customer considerations into the investment planning methodology and overall investment strategy.

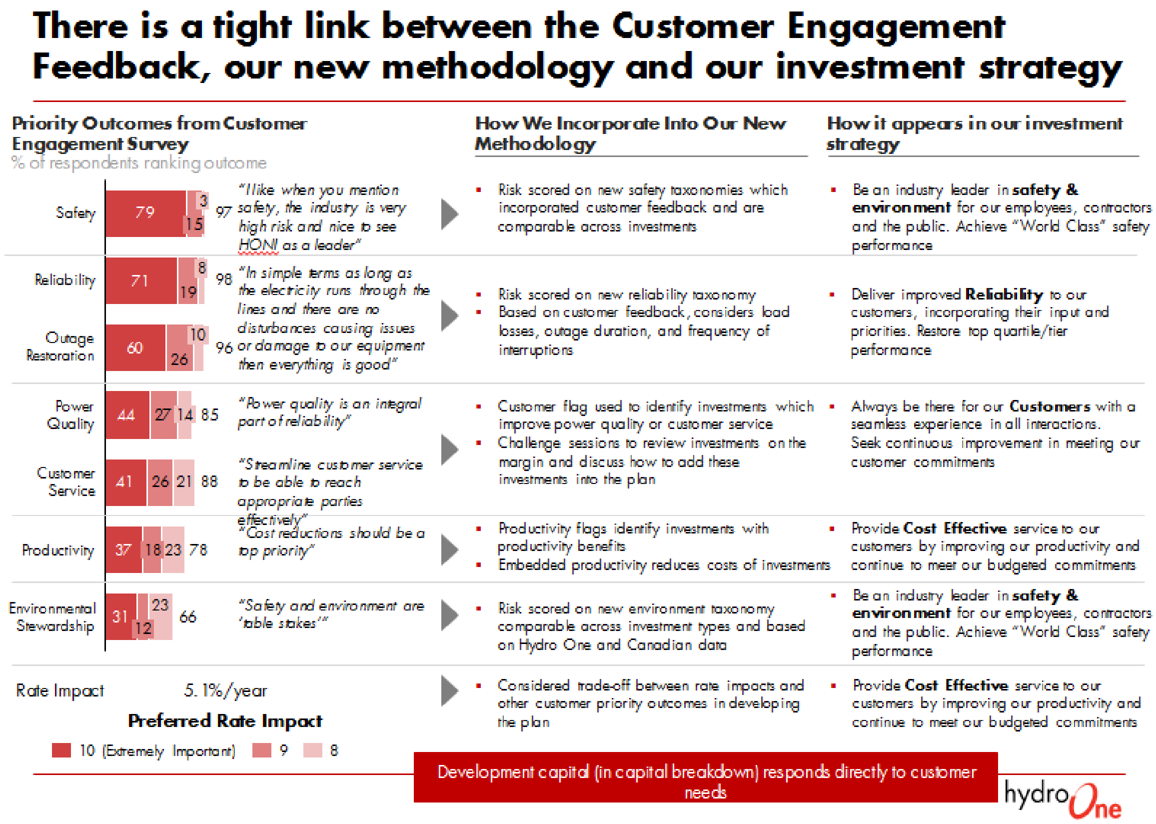

Figure 1 - Incorporation of Customer Considerations Into the Investment Strategy

Section 2.1 of the TSP explains how customer feedback is considered in Hydro One's investment planning process. Section 3.2 of the TSP explains how the proposed capital expenditure plan reflects the outcomes valued by customers.

1.3.2 (5.2.2 A) CUSTOMER ENGAGEMENT SURVEY

The Transmission Customer Engagement Survey process enables Hydro One to engage in formal discussion with its transmission customers for the purpose of obtaining feedback to inform Hydro One's investment planning process. This process aligns with Hydro One's vision to be a customer-focused commercial entity with a transmission investment plan that will drive the outcomes that customers value by demonstrating responsiveness to identified customer needs and preferences, including how to make trade-offs between outcomes and costs.

1.3.2.1 BACKGROUND AND OBJECTIVES

In 2016, Hydro One introduced a Transmission Customer Engagement Survey process. The approach taken by Hydro One in its 2017 survey was improved by incorporating lessons learned and addressing comments made about the 2016 survey.

In 2017, Hydro One engaged Innovative Research Group ("IRG"), an experienced third party research and consultation firm, to develop and implement a second iteration of the Transmission Customer Engagement Survey process (as outlined in Appendix 1). Content for the 2017 Transmission Customer Engagement Survey incorporated lessons learned from the 2016 Survey process, including feedback received from the OEB and interveners in the last transmission rate proceeding (as outlined in Appendix 2). This content established a framework for Hydro One to obtain useful, credible and unbiased information to guide the investment and business planning efforts that underpin this TSP.

The scope of the 2017 survey was also expanded beyond the level of investments. In 2016, customers were mostly asked what funding level was appropriate. In 2017, the survey sought customer feedback regarding which investments should be prioritized by evaluating what outcomes customers valued.

Through the 2017 Transmission Customer Engagement Survey process, Hydro One further developed its understanding of the needs and preferences of its transmission customers that were considered at various points in Hydro One's investment planning process. Hydro One carried out this customer engagement process early in the planning process to allow sufficient time for customer needs and preferences to be considered and integrated into the transmission investment planning and business planning processes.

Detailed results of the 2017 process are set out in the IRG Customer Engagement Report provided in Attachment 1. Appendix 1 outlines the process and timing of the engagement survey, and Appendix 2 outlines the feedback heard from OEB staff and interveners regarding the 2016 process and the specific steps taken to address that feedback as part of the 2017 process.

1.3.2.2 (5.2.2 B) SUMMARY OF CUSTOMER NEEDS AND PREFERENCES

All transmission-connected customers were invited to participate in Hydro One's customer engagement survey. Over 100 Hydro One transmission-connected customers participated in the 2017 Transmission Customer Engagement Survey, reflecting a participation rate of 66%. This improved level of participation reflected the involvement of 103 out of Hydro One's 156 transmission-connected customers including a large number of LDCs. These 2017 participation rates were 51% higher than those of the 2016 customer engagement.

Hydro One's Transmission Customer Engagement Survey process yielded valuable feedback concerning the specific needs and preferences of its transmission-connected customers to shape Hydro One's investment plans. The prioritized list of outcomes valued by Hydro One's transmission customers is presented in the figure below (reproduced from Attachment 1):

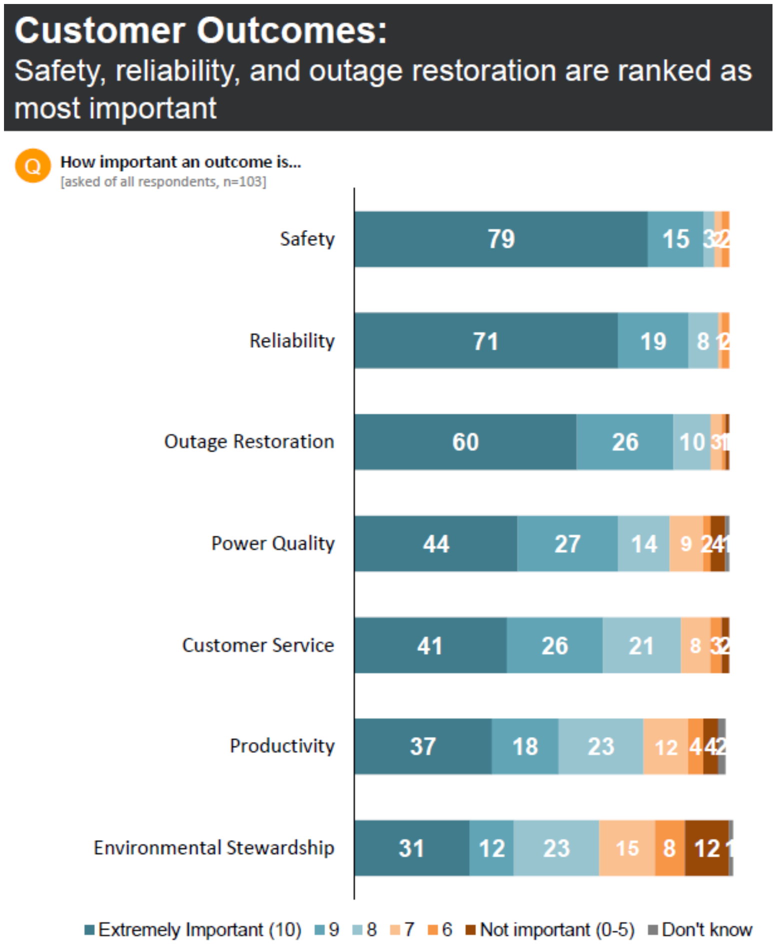

Figure 2 - Customer Outcomes

The key messages and results received by Hydro One from the 2017 Transmission Customer Engagement Survey are as follows:

- Safety, reliability, and outage restoration are customers' top prioritized outcomes;
- All customer segments prefer to see investments spread out over time versus investing now with higher rates in the short term and lower future increases or delaying investments with lower rates in the short term and higher future rates;
- Reducing the frequency of outages is more important than reducing the duration of outages. However, the most important issue is to reduce the number of day-to-day interruptions;

- When presented with several investment scenarios, the majority of customers preferred investment levels in line with the investment plan that was before the OEB in the Prior Proceeding by at least a three to one margin. It is seen as reflective of the current approach which has served the system well, and a less risky option; and
- About half of end-user participants (19 of 38) rate power quality as an “extremely important” outcome.

Despite different perspectives, most customers agreed that improvements in both frequency and duration of outages are among their top needs. Power quality and transmission capacity were also raised as major issues facing customers, particularly in northern Ontario. Cost was also raised at various times throughout the survey. The desire for good reliability at a competitive or low cost was universal.

1.3.3 (5.2.2 A) CUSTOMER SATISFACTION SURVEYS AND RESEARCH

In addition to Hydro One's customer engagement surveys, Hydro One regularly solicits feedback from customers through a variety of channels to be leveraged throughout Hydro One's planning process.

1.3.3.1 CUSTOMER SATISFACTION SURVEYS

Since 1999, Hydro One has been collecting feedback from transmission customers through an annual customer satisfaction research process. The customers surveyed are critical to the success of Hydro One's business, and are also critical to the communities in which they operate. The trending of results over time assists Hydro One in identifying areas to improve transmission customer satisfaction. Hydro One uses this data to inform and improve business practices and stay informed about the trends that matter most to transmission customers. Customer Satisfaction scores are also included in Hydro One's Corporate Team Scorecard (Exhibit F, Tab 4, Schedule 1, Attachment 4) and Hydro One's proposed Transmission Scorecard (as described in Section 1.5 of the TSP).

This research is conducted by independent expert customer research firms. The most recent iteration of this research was carried out and reported on by Innovative Research Group in 2018 and is described in Section 1.5 of the TSP.

The objectives of the Large Transmission Customer survey are to measure the level of customer satisfaction, and to monitor Hydro One's performance in four dimensions of satisfaction among customers: Price, Customer Service, Product Quality/Reliability and Relationship. The survey measures customer perceptions of the Company (whether they have interacted with Hydro One recently or not), with a specific focus on how well the Company meets expectations and delivers on critical success factors. The survey is administered to transmission-connected Generators, End Users and all LDCs. The customer survey research is used to evaluate the overall satisfaction levels of these customers groups, and to better understand their perceptions of Hydro One.

Figure 3 illustrates the trend of the overall satisfaction results. In 2018, Overall Satisfaction was at the highest point in the past seven years at 90%, which is a 12% increase since 2016. The increase in overall satisfaction can be attributed to LDCs and generation customers. The main driver identified through analysis for higher customer satisfaction was customer communication and key account managers. The identified driver correlated with lower satisfaction was the ability to recall a planned outage. Additional information can be found in TSP Section 1.5 and the complete 2018 survey results can be found in Attachment 5 to this exhibit. The greatest dimension of high customer satisfaction was customer service, with 93% satisfaction with communications methods, 93% satisfaction with customer service overall and 90% satisfaction with key account services from account executives. A majority, 60%, are satisfied with Hydro One’s product. Some dimensions with lower product satisfaction include number of unplanned outages, a dimension 50% of customers are dissatisfied with.

Figure 3 from Exhibit B1, Tab 1, Schedule 1, Section 1.5 – Overall Customer Satisfaction, Corporate Survey (% satisfied)

1.3.3.2 (5.2.2 B) ONTARIO GRID CONTROL CENTRE TRANSMISSION CUSTOMER SURVEY

Hydro One's Ontario Grid Control Centre ("OGCC") has surveyed satisfaction among its medium and large business customer satisfaction since 2013. The main objective of the survey is to determine key dimensions of satisfaction, strengths, and opportunities and to improve customer service policies, service delivery processes and communications in the areas of accountability of the OGCC such as outage planning and interruption restoration information. Overall satisfaction with OGCC has improved over the past year (98% in 2018 vs. 94% in 2017). The greatest driver of OGCC customer satisfaction was communications and responsiveness. Hydro One's average performance over the past five years was 90 per cent, and the overall trend indicates that satisfaction with outage planning procedures is improving. Over the rate period, Hydro One plans to maintain its historical average, targeting 90 per cent satisfaction with outage planning procedures.

Additional information can be found in TSP Section 1.5. The complete 2018 OGCC customer survey results are provided as Attachment 6 to this exhibit.

1.3.4 (5.2.2 A) ONGOING CUSTOMER ENGAGEMENT

Hydro One believes that understanding customers, and their needs, is critical to a successful business. Hydro One engages with customers regularly and through different mechanisms. Customer needs can be categorized as either (i) initial connection needs, or (ii) needs of connected customers.

Initial connection needs are generally identified either through the Hydro One customer connection process or by need assessments and customer consultations under the regional planning process, as described in TSP Section 1.2. The regional planning process ensures that needs are assessed and identified by Hydro One in conjunction with customers, the IESO and LDCs.

Once connected, customer needs are identified by continuous monitoring of the power system. Hydro One planners continuously engage with customers (e.g. LDCs, industrial and commercial transmission-connected customers) to discuss and solicit feedback on investments to address end of life asset replacements. Open dialogue with customers during the planning stages of candidate investments ensures customers' needs and preferences are addressed in a collaborative manner, and it allows customers to have a voice regarding technical system requirements such as improved station configuration to enable greater operational flexibility, and changes in work execution practices and processes that impact customers. Customer feedback also provides valuable information that planners incorporate into the Investment Planning Process during the Asset Risk Assessment ("ARA") process (discussed further in TSP Section 2.1) to inform the development of investment candidates.

1.3.4.1 ONGOING CUSTOMER ENGAGEMENT SURVEY (RRFE)

Hydro One is implementing an Ongoing Customer Engagement Questionnaire that will quantify transmission customers' satisfaction regarding a variety of reliability focused measurements. The Questionnaire asks about customer satisfaction with Hydro One's current work program; satisfaction with outages, power quality, and reliability; investment priorities; unplanned outages mitigation and impact; and rate impacts.

Although the questionnaire asks customers to rank satisfaction of key indicators on a scale of 1-5, the survey also addresses specific preferences, asking customers if they would prefer shorter and more frequent outages or longer and less frequent outages, for example. Results of these questions will be inputted into Hydro One's Customer Relationship Management system, which keeps records of customer agreements, issues complaints, feedback and CSAT results. These questionnaire results will directly inform Investment Planning on problem areas that need to be mitigated, as well as broader customer preference trends to apply across the system. The questionnaire will be done on an annual basis to give planners a continuous source of customer information beyond CSAT scores, beginning in 2019.

Directly connected transmission customers currently receive an annual reliability report which summarizes historical and annual performance at transmission and distribution delivery points, describes investments recently made in the customer's area, investments planned in the customer's area and upcoming maintenance in the customer's area. The reliability report allows customers to provide informed input into customer engagement touch points, such as Hydro One's new Ongoing Customer Engagement Questionnaire.

1.3.4.2 LARGE CUSTOMER ACCOUNT MANAGEMENT

The Large Customer Account Management Group (formerly, "Customer Business Relations") provides customers with a single point of contact at Hydro One for all types of interactions. In particular, this group communicates with customers on matters that include customer connection requests, sustainment and system development plans and projects, and concerns regarding service levels or power quality.

Account Executives from Hydro One’s Large Customer Account Management Group meet with transmission customers on a regular basis to ensure that the needs of customers are identified and discussed, and action plans are developed to address these needs. If an action plan results in new or modified connection facilities and/or asset needs, then the Account Executive will directly communicate with the affected customer(s) to ensure a common understanding of the related connection process and contractual requirements, such as connection cost estimates and capital cost recovery agreements. Examples of investments included in this TSP that have resulted from direct communication by Account Executives in Hydro One’s Large Customer Account Management Group with customers, are Enfield TS and the Seaton MTS Connection. Hydro One’s transmission system planners developed candidate projects to address the customer needs identified in action plans. Risks associated with each of these candidate projects were considered throughout Hydro One’s investment planning process and resulted in the inclusion of the Enfield TS and Seaton MTS Connection projects in Hydro One’s capital expenditure plan.

Hydro One’s Account Executives proactively engage with transmission customers to review and coordinate planned outage activities to minimize impacts on customers and to optimize opportunities for both Hydro One and customers to plan and execute work on their respective facilities. The outcomes of these discussions are used as inputs to the OGCC’s Transmission System Outage (“TSO”) process to coordinate multiple work activities on the same equipment during a single outage, as discussed further below. Account Executives also participate in the OGCC’s meetings with customers to discuss planned outages and work as part of the regional planning process, discussed in TSP Section 1.2.

In 2018, Hydro One addressed the OEB’s finding that: “Hydro One should improve its internal institutional processes to better inform the transmission performance management system of distribution customers’ satisfaction level for the purpose of gauging what, if any, elements of transmission operation are the cause of any dissatisfaction".[1] In response, among other things, the Company began consolidating the service delivery model for its largest customers having a 2 MW demand or more including Hydro One's distribution-connected end use consumers. This change will introduce a similar level of customer service for Hydro One's Large Distribution Accounts ("LDA") that Hydro One's transmission-connected customers currently receive, including the assignment of Account Executives to LDA customers, tracking of customer information and interactions, and identifying opportunities for advocacy for these large customers across the company.

In particular, this approach will facilitate the consistent and more complete reporting of customer needs and preferences for use by planners, operators and customer service teams to consider when making transmission planning and investment decisions. Further details in respect of how Hydro One addressed the OEB's findings quoted above are set out in Appendices 1, 2 and TSP Section 1.5.2.

1.3.4.3 OGCC'S CUSTOMER OPERATING SUPPORT AND OUTAGE PLANNING GROUP

The OGCC's Customer Operating Support Group works directly with transmission customers to efficiently plan real-time outage operations, coordinate planned outages so Hydro One or the customer can complete required work, to respond quickly to unexpected outages, and to coordinate switching activities.

The Outage Planning Group organizes bi-annual customer meetings throughout the province to coordinate outage planning activities. These meetings are a key activity in Hydro One's TSO process. The OGCC sends reports, customized for individual customers that provide a rolling, one-year window of the planned outages that will affect

[1] EB-2016-0160, Decision and Order (November 1, 2017), pp. 38-39

the customer's delivery point. These reports contain information on outage start and end dates, the equipment involved, purpose, recall time and schedule profile. The reports provide an opportunity for customers to provide feedback. The Outage Planning Group also provides information on Hydro One's plans, particularly with respect to outages, for the balance of the year and/or the next scheduling year. During these meetings, customers may bring forward their own maintenance plans for their facilities, with a view to scheduling or bundling outages in a manner that minimizes the frequency and duration of outages for both the utility and the customer.

1.3.4.4 LARGE CUSTOMER CONFERENCE

Each year, Hydro One organizes and hosts a Large Customer Conference for all large transmission and large distribution (2 MW+) customers. The focus of the conference is to provide an opportunity for large customers to hear about Hydro One's plans and initiatives, ask questions, discuss their interests, and raise concerns with representatives and executives from several Hydro One lines of business. To ensure that the conference addresses the specific areas of interest for these customers, Hydro One seeks customer input prior to the conference to inform the conference agenda. This provides initial insights into the issues that are top of mind to Hydro One's large customers. At the conference, customers who are directly connected to the transmission system are presented with information about significant upcoming Hydro One initiatives that may affect them, including any technological changes they would need to be aware of or other potentially impactful initiatives.

In recent years, Hydro One has used these conferences as an opportunity to provide large customers with presentations about Hydro One's planned investments and activities. In addition, large customers are given an opportunity during each Large Customer Conference to meet with Hydro One staff, including Planning staff, to share information and raise concerns. In addition to Planning staff learning about customer needs and preferences through these informal conversations, feedback received during the conference, and through post-conference customer surveys, is subsequently provided to Planning for further consideration. Recent feedback suggests that customers would like to hear more about reliability, maintenance procedures and lowering recall time in outages.

1.3.5 (5.2.2 A) OVERSIGHT COMMITTEES AND WORKING GROUPS

Hydro One has established a number of oversight committees (and in the case of Metrolinx, a working group) to engage and obtain feedback from customers on topics with a high level of customer interest. Ongoing coordination with other entities is particularly valuable where there is a need for coordinated health and safety oversight. The purpose and value of the oversight committees is to ensure that the ongoing operational needs and preferences of these customer groups are accounted for in a timely and tactical fashion. The purpose of these oversight committee meetings is not expressly to direct investment plans, although the oversight committees can give an early insight as to future investment needs more generally. To date, Hydro One has established and maintains a number of oversight committees as follows.

1.3.5.1 SARNIA AREA RELIABILITY OVERSIGHT COMMITTEE

The Sarnia Area Reliability Oversight Committee consists of Hydro One staff and industrial and generation-connected customers and LDCs in the Sarnia Chemical Valley area. Chemical Valley customers include a large number of facilities and refineries with very sensitive manufacturing processes. The industry in the Sarnia area is particularly concerned with reliability and power quality such as loss of supply, loss of redundancy, and voltage fluctuations that can result in possible wide spread health and safety issues such as gas flares and cause very costly damage to customer manufacturing equipment and halt their processes. This committee meets twice a year to identify issues regarding reliability in the Sarnia Area and to review proposed annual work plans to ensure that issues will be addressed appropriately, having regard for the environmental and safety concerns of these customers.

1.3.5.2 LDC WORKING GROUP

Hydro One facilitates an LDC working group, which serves as a forum to update and communicate with LDCs on Hydro One’s transmission-related policies and practices, identify emerging issues, as well as solicit input to enhance customer experience. This group meets three to five times annually.

1.3.5.3 TORONTO HYDRO OVERSIGHT COMMITTEE

Hydro One holds quarterly Oversight Committee meetings with Toronto Hydro-Electric System Limited to identify and resolve issues and to coordinate efforts on capital projects and other matters. This forum allows the two utilities to coordinate their operations in a safe and efficient manner.

1.3.5.4 SWITCHYARD OVERSIGHT COMMITTEES

Hydro One facilitates and participates in switchyard oversight committees with Bruce Power Inc. and Ontario Power Generation Inc. These committees assist the parties in overseeing and coordinating matters of mutual interest, such as interface equipment, procedures and policies that pertain to Hydro One equipment at nuclear generation facilities. These committees ensure the safe and efficient operation of switchyards at Ontario's nuclear generation facilities, help maintain compliance with legal requirements, and allow for the efficient coordination of capital projects and other matters. These committees each meet approximately three times each year.

1.3.5.5 METROLINX WORKING GROUP

Hydro One's Metrolinx Working Group provides a forum to reviews issues arising during the large scale transportation infrastructure work that Metrolinx is undertaking in Ontario. This working group is made up of staff from Hydro One's Large Account Management, Real Estate, and Transmission Planning groups and staff from Metrolinx. The working group reviews and addresses customer escalations arising from the Metrolinx work program and ensures that issues are addressed in a timely manner.

1.3.5.6 HYDRO OTTAWA OVERSIGHT COMMITTEE

The Hydro Ottawa Oversight Committee was established in 2018 and provides a forum for Hydro Ottawa and Hydro One to meet twice a year to identify and resolve any issues and to ensure safe and efficient operations between Hydro One and Hydro Ottawa. Meetings also allow the parties to coordinate efforts relating to capital projects and other matters.

1.3.6 (5.2.2 A) INCORPORATING CUSTOMER NEEDS INTO THE PLAN

Insights from recent surveys reveal customers are seeking improvements in the following areas:

- Safety, reliability, and outage restoration are customers' top prioritized outcomes;
- All customer segments prefer to see investments evenly spread out over the long term;
- Reducing the frequency of outages is more important that reducing the duration of outages. However, the most important issue is to reduce the number of day-to-day interruptions;
- The majority of customers prefer to maintain levels of investment in line with the proposal filed in Hydro One's last transmission rate application (EB-2016-0160), rather than to increase or decrease investment levels;[2]
- End user participants rate power quality as an "extremely important" outcome;
- Reliability metrics used by Hydro One do not adequately capture events on the network that may actually be associated with power quality;
- Customers would like to have more assistance investigating power quality events;
- Customers would like reduced timelines for connection estimates;
- Customers would like lower connection costs;
- Customers desire improved communication and transparency; and
- Customers believe Hydro One should be easier to do business with.

Hydro One's full spectrum of customer engagement initiatives is leveraged to increase its understanding of customers' needs and preferences; enhance Hydro One's ability to provide the expected level of service; produce outcomes that are valued by customers;

[2] Customer preferences are set out in Attachment 1 of Section 1.3 of the TSP.

and result in an improvement to customers' overall satisfaction with Hydro One's Transmission business.

As part of the multi-step investment planning process described in TSP Section 2.1, planners develop a set of candidate investments that are designed to address the relevant asset needs and risks, and incorporate transmission customers' needs, preferences and feedback to inform the capital expenditure plan.

1.3.6.1 IDENTIFYING TRENDS

Cross functional sessions are held to review all customer engagement results, identify broad trends and specific customer needs and preferences. This review provides a basis to capture customer needs and preferences in the investment planning process and improve alignment between individual candidate investments identified by planners and the outcomes of the customer engagement activities.

1.3.6.2 INVESTMENT ASSESSMENT

Since the last transmission rate application, Hydro One has introduced investment planning process improvements, including a revised scoring process and a formalized flagging framework as described in TSP Section 2.1.4. The feedback provided through the customer engagement process informed the enhanced risk and scoring framework. In particular, the revised scoring process focuses on assessing risk related to safety, reliability and environmental considerations. These three outcomes are among the top customer priorities identified and validated through Hydro One's customer engagement. As risk scoring is the dominant evaluation method for candidate investments, customer needs and preference are reflected in all risk-scored investments.

In addition to investment scoring for safety, reliability and environmental risk, investments are flagged for factors including customer needs and preferences identified through the engagement process. A full list of flags is included in TSP Section 2.1.4.2.

Examples of customer needs and preferences that were identified through customer engagement and flagged include:

- Concerns expressed with delivery point performance as a result of nuisance wildlife or equipment configuration;
- Coordination of asset maintenance and replacement activities with generator customers during planned outages to minimize disruptions to operations;
- Concerns expressed with power quality; and
- Addressing worst performing delivery points (outliers).

1.3.6.3 CALIBRATION SESSIONS

Following the development of investment candidates and risk scoring, structured calibration sessions are held to ensure that scoring and the application of flags is consistently applied across the organization. Based upon business knowledge gathered through customer-facing efforts described earlier and results obtained through the Transmission Customer Engagement Survey, management validates that the investments are responsive to customer needs and preferences by comparing the description of the need/preference with the high level themes identified through the customer engagement results.

1.3.6.4 OVERALL FUNDING ENVELOPE

The feedback received through the customer engagement process influenced the company's decisions around the overall funding envelope. As part of the customer engagement survey, respondents were provided with descriptions of four illustrative investment scenarios. They were then provided with a line of data points that started at zero and extended beyond all four of the illustrative investment scenarios. Customers were asked to select any point along that continuum that reflected what they believed to be the best and most appropriate balance between rates impacts and outcomes:

- Scenario A was based on limited investment;
- Scenario B involved a decrease in the current level of investment;

- Scenario C would maintain the current level of investment; and
- Scenario D would increase beyond the current level of investment.

Scenario C, which maintains the current level of investment proposed in EB-2016-0160, reduces reliability risk, improves long-term reliability performance and offers level future rate increases, was strongly favored over the other three scenarios with 24% of respondents selecting this scenario. Respondents indicated their preference through the selection of a point along a line showing the spectrum of scenarios; 21% chose a point between Scenario B and Scenario C and 17% chose a point between Scenario C and Scenario D. This clustering informed the initial funding envelope.

1.3.6.5 PRIORITIZATION, OPTIMIZATION, ENTERPRISE ENGAGEMENT AND MANAGEMENT REVIEW AND APPROVAL

Following review and calibration, all candidate investments were aggregated into a consolidated portfolio for prioritization with a view to reflecting the level of investment most preferred by customers in the customer engagement exercise. While the initial prioritization and optimization is risk based, subsequent structured and facilitated trade-off discussions identify projects on the margin and determine allocation of funding based on consideration of investment merits from both risk and non-risk perspectives, such as the appropriate incorporation of customer needs and preferences.

Ultimately, Hydro One determines a funding envelope that balances identified transmission customer needs and preferences with rate impacts and asset/system needs. These considerations are integral in the review and final approval of the Business Plan by the Executive Leadership Team and Board of Directors.

The manner in which the proposed capital expenditure plan reflects the aforementioned transmission customer engagement initiatives, including in particular the 2017 Transmission Customer Engagement Survey process, is discussed in TSP Section 3.2.2.

1.3.7 ATTACHMENTS: CUSTOMER ENGAGEMENT

Attachment #1 - Customer Engagement Survey

Attachment #2 - Stakeholder Engagement Session Presentation Slides

Attachment #3 - Stakeholder Session Notes

Attachment #4 - Reliability Risk Summary

Attachment #5 – Large Tx Customer Satisfaction Survey Report

Attachment #6 – OGCC Customer Satisfaction Survey – 2018 Results

APPENDIX 1: CUSTOMER ENGAGEMENT PROCESS AND TIMING

Managers and Executives from Hydro One's Customer Service, Planning and Regulatory groups met in February 2017 to plan and prepare for the 2017 Transmission Customer Engagement Survey process, with a view to using the results of this initiative to guide and inform the investment planning process as part of this Application.

Hydro One determined that all of its transmission-connected customers would be invited to participate in this process and that, given the discrete number of transmission customers (in comparison to the number of customers that need to be engaged with to support preparation of a Distribution System Plan), this effort would be qualitative rather than quantitative (i.e., it would provide guidance directionally, but not statistically, due to the limited population size of the transmission customer base). The survey was also developed based on the engagement sessions with stakeholders from the 2017/2018 application.

The 2017 Transmission Customer Engagement Survey process was implemented based on the following schedule.

Description	Date
Final Survey Submitted	03-May-17
Survey In Field	11-May-17 – 15-Jun-17
Interim Report	31-May-17
Survey Concluded	09-Jun-17
Final Report	02-Jul-17

Findings were used to inform the plan as it was iteratively developed through the planning and feedback process.

Detailed results of the 2017 process are set out in the IRG Customer Engagement Report provided in Attachment 1.

APPENDIX 2: INCORPORATING FEEDBACK INTO THE CUSTOMER ENGAGEMENT SURVEY

Hydro One's approach to engaging transmission customers has evolved, and continues to evolve, in response to the OEB's recommended areas for improvement as set out in its September 28, 2017 Decision and Order in proceeding EB-2016-0160. In particular, the OEB found that Hydro One should (i) begin its customer engagement process sufficiently in advance of filing the application to allow for timely input to be incorporated in a meaningful way and to improve the level of customer attendance; (ii) include LDCs so as to determine practical ways to seek some input from their end users; (iii) incorporate timely and meaningful input from First Nations representatives; (iv) ensure that information presented to customers is unambiguous and easy to understand.[3]

The 2017 Transmission Customer Engagement Survey was designed to be responsive to feedback heard from OEB staff and intervenors in the EB-2016-0160 proceeding and is consistent with the Board's findings in its Decision and Order. Hydro One made a number of improvements that address the Board's findings.

FINDING 1: TIMING OF CUSTOMER ENGAGEMENT SURVEY

The 2017 engagement survey was completed prior to the Investment Planning Context phase of the Investment Planning Process outlined in Section 2.1 of Transmission System Plan.

FINDING 2: INCLUDE FEEDBACK FROM LDC END-USERS

Hydro One's transmission system is the upstream supplier of electricity to LDCs across the Province of Ontario. Electricity is transmitted over the Hydro One transmission system to Delivery Points ("DPs") with the LDCs. DPs are boundaries between the electricity systems of Hydro One and the LDCs. Each LDC has significant power

[3] See OEB, Decision and Order in EB-2016-0160, September 28, 2017, pp. 24 and 117.

requirements, unique needs, a diverse group of end-use customers, and most importantly, distribution systems designed to meet their requirements and needs, to service their end-use customers. There is no direct link between the Hydro One transmission system and the LDC's end-use customers.

In Hydro One's 2017 Transmission Customer Engagement Survey, Hydro One asked LDCs to identify whether their responses to the survey were informed by their own customer engagement activities for the purposes of their own rate applications, or by any other customer research. Of the 28 respondents, 11 answered "yes" to this question. Additionally, Hydro One's Account Executives interact with the LDCs, and engage the LDCs in discussion regarding the needs of their ultimate end-use customers, as described above. Results from these inputs were considered by Hydro One during its investment planning process. In addition, Hydro One noted that in customer surveys conducted by other LDCs, residential customers, small business customers (general service<50 kW), and mid-market customers (general service>50 kW) consider price their number one priority and reliability their number two priority whereas larger demand key accounts prioritize reliability over price. These results demonstrate the importance of keeping costs as low as possible while maintaining system integrity to ensure reliable service to businesses in the province.

Subsequent to the issuance of the OEB's decision, Hydro One contacted some LDCs to solicit further approaches it could use to solicit feedback from LDC end-users, in the future. The feedback from LDCs included: (i) suggestions to continue using the account executive model to serve the needs of LDC customers, a program Hydro One has expanded as described above; (ii) that Hydro One meet with the large industrial customers of other LDCs, with Hydro One executives responding to customer concerns. Hydro One executed this suggestion and will facilitate future meetings as requested by LDCs; and (iii) that Hydro One may review LDC survey information. As indicated above, Hydro One considered the results of other LDCs customer surveys during its investment planning process.

FINDING 3: INCORPORATE INPUT FROM FIRST NATION REPRESENTATIVES

As noted, one message that Hydro One heard in the last transmission rate proceeding was that First Nations customers were not effectively represented in Hydro One's transmission customer engagement process, nor was any particular process in place to specifically engage with these customers. To respond to this concern, Hydro One asked LDC customers who serve First Nations communities whether there was anything in particular they felt Hydro One could do to better serve the specific needs of First Nations and Métis communities. Hydro One also leveraged its ongoing engagement activities with First Nations and Metis communities to identify customer needs and preferences for these customers. Details of Hydro One's ongoing initiatives can be found in Exhibit A, Tab 7, Schedule 2.

FINDING 4: ENSURE INFORMATION PRESENTED TO CUSTOMERS IS EASY TO UNDERSTAND

Finally, the design of the 2017 engagement survey included information that was purposefully written to ensure the content was unambiguous, sufficiently informative for customers to respond to, and easy for customers to understand. To gauge the quality and clarity of the information, the survey included a post-survey question asking "Did Hydro One provide too much information, not enough or just the right amount?" The result was that 76% of respondents believed the survey contained just the right amount of information.

Stakeholder Session

A stakeholder session, which included OEB staff and interveners who participated in prior Hydro One transmission rate proceedings, was held on March 22, 2017. The session aimed at gathering thoughts and insights from stakeholders on Hydro One's prior customer engagement activities. The feedback provided during this session was addressed as part of the 2017 Transmission Customer Engagement Survey process, as summarized in Table 1 below.

Table 1 - Summary of Feedback Received by OEB Staff and Interveners and Hydro One's Actions Taken

Feedback Received	Action Taken
Consultation did not take place early enough to have impacted business decisions.	The 2017 Transmission Customer Engagement report was released to Hydro One planners in 2017 and was incorporated into the iterative planning process undertaking in 2018.
Participation rates were low in the 2016 Transmission Customer Engagement effort, and did not represent the ones who will feel the impact of an increase (i.e., end-users of LDCs).	Hydro One invited all transmission customers to participate in the survey via a variety of channels. For the 2017 survey, 103 of 153 customers, or 66% of Hydro One transmission-connected customers, participated in the survey including a large number of LDCs.
A subset of the majority of attendees does not pay transmission rates directly and, therefore, Hydro One addressed the wrong audience.	A section for LDCs was added to the survey to address this concern, asking for the LDC's feedback to be provided on behalf of their customer base.
The costs of improved reliability and top quartile status were not fully explained to participants, impacting customer perception and whether they were willing to approve increased spending approvals.	A broader spectrum of options and enhanced details about each option were provided as part of investment outcomes.
There was a perceived endorsement of the middle investment scenario option and survey participants did not have enough options with 3 scenarios presented.	Customers were provided 4 detailed scenarios (as referenced in Attachment 1) and, when indicating their preference, were not constrained to choose one of the four scenarios, but rather respondents were asked to choose a point on a continuum (a total of 17 possible responses).
There was a perception that risks were exaggerated impacting customer perception to approve increased spending	IRG was asked to correct any wording used as part of the survey that could be perceived as 'leading' and additional information was provided in supplementary

Feedback Received	Action Taken
approvals, and that the risk model was not mature or predictive.	materials to better explain how and when the Hydro One Reliability Risk Model[4] is used. A broader spectrum of outcomes beyond reliability risk was provided to customers for each investment scenario to allow for more informed selections.
First Nations Customers were not represented and no consultation process was in place.	Hydro One engages with First Nation customers on a regular basis through a variety of channels (as outlined in Exhibit A, Tab 7, Schedule 2). Although Hydro One has no First Nation transmission customers, LDCs who serve First Nations and Métis Nation customers were asked specifically to provide feedback on how Hydro One could improve service to these customer segments. Of the LDC customers served by Hydro One who self-identified as serving First Nations and Métis communities, two provided a response. One indicated that Hydro One did not need to do anything else. The other stated that, "The northern single circuit communities deserve more attention as they are more vulnerable in terms of supply and outage response." This feedback was considered when assessing the overall pool of investments addressing lower performing sections of the transmission system. Hydro One actively monitors all customer delivery point performance and invests in the system to address customer power quality concerns. Significant investment is planned in wood pole replacements, where the majority of the asset population is located in northern Ontario, along with transmission line refurbishments to address poor condition assets that pose a high risk to customer reliability.
Customers may not have fully understood what was being asked of them.	Links were included in the survey that took customers to a second document with more contextual information and definitions of terms used in support of the survey.
Confusing terms were used by Hydro One as part of the survey with terms used interchangeably, confusing customers (outage, interruption, end of useful life, expected service life, etc.).	The survey was carefully developed to be consistent with the use of terms throughout the survey process. Clarity on terms was provided in the supporting materials described above.

[4] Further details regarding the reliability risk model are provided in Attachment 4.

An additional discussion on end-user customers is presented in TSP Section 1.5.2, *Responses to OEB Directions from EB-2016-0160, LCD End-User Satisfaction.*

The presentation slides and summary notes from this stakeholder session are provided as Attachments 2 and 3 to this section of the TSP.

INNOVATIVE
RESEARCH GROUP

Hydro One

Transmission Customer Engagement

JULY 2017 | REPORT

STRICTLY PRIVILEGED AND CONFIDENTIAL

Table of Contents

Survey Methodology

Overview:
Innovative Research Group (INNOVATIVE) was commissioned by Hydro One to conduct a customer engagement survey with its 156 transmission customers. INNOVATIVE worked closely with Hydro One to ensure that the survey structure and all questions were methodologically sound and that all data was collected in a private and secure manner. The results of the survey will be used as input for Hydro One's 2019 to 2023 business plan.

Sample Frame:
Hydro One and INNOVATIVE made efforts to contact all 156 Hydro One transmission customers to participate in this engagement (see details below). From a list of 156 customers, a total of 103 completed the survey.

Methodology:
In order to meet the needs of senior executives, customers were given the option of participating online on a custom site created and hosted by INNOVATIVE, or through an in-person or telephone interview with a senior INNOVATIVE consultant. While most customers chose to use the online tools, one customer requested an in-person interview and three opted for a telephone interview.

The survey design kept the amount of background information to a minimum in recognition of the high level of electricity system knowledge of many participants. To assist customers who are less engaged in the system, additional information (see Appendix 1.3) was made available to all survey participants, either with "click to access" buttons throughout the online survey, or in a standalone document for those who completed an in-person or telephone interview.

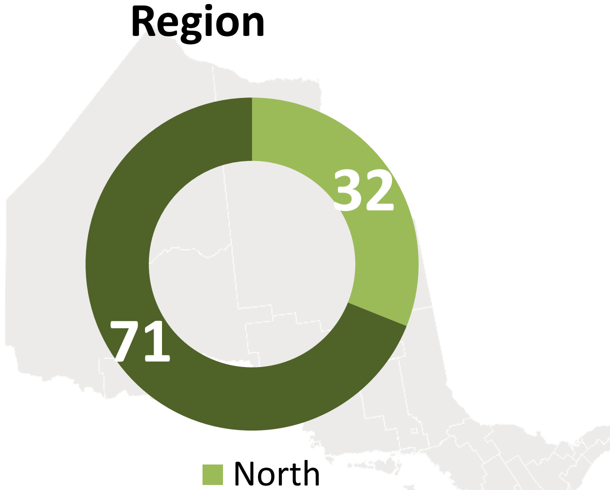
Where possible, invitations were initially extended through a phone call from Hydro One account executives and INNOVATIVE researchers. Most (n=142) customers were successfully contacted by phone and all but nine of this group (who stated they were not interested) were subsequently sent an email from INNOVATIVE which contained an individual URL for the survey site. Twelve customers who were not reached by phone were sent an email invitation which included a direct link to the online survey, along with contact details for an INNOVATIVE consultant should they wish to do an in-person or telephone interview. There were only two customers who could not be reached by email or by telephone.

Field Dates:
May 11th to June 15th, 2017

Participant Segmentation

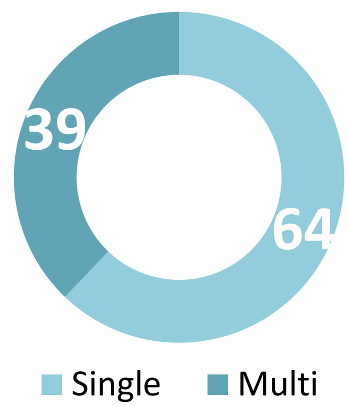
Hydro One understands that its customers have differing needs and preferences. To understand these differences, Hydro One asked that the results be presented in certain segments, as described below.

Region



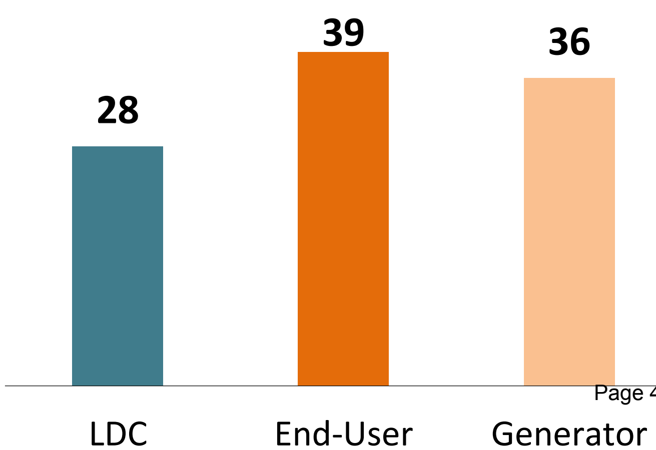
Northern customers commonly use a large percentage of the power delivered by their respective lines. Lines in the North tend also to be relatively long in length. Southern customers are generally more tightly integrated into a larger grid and more frequently share lines with many other transmission customers.

Single/Multi Circuit



Multi-circuit customers have relatively low frequency of outages given the inherent redundancy. Single circuit customer do not benefit from redundancy and have a much higher risk of outage when an interruption in the system occurs.

Business Segment



Local Distribution Companies (LDCs) take power and distribute it to other customers within their franchise area. End Users take power directly and use the power for their own purposes. Generators deliver power to the transmission system, often in very large quantities.

INNOVATIVE RESEARCH GROUP

Executive Summary (1)

Response to the Customer Engagement

Of Hydro One’s 156 transmission customers, a total of 103 participated in this customer engagement – a response rate of 66%. Every customer who started the survey reached the end of the survey, where they were asked to provide feedback on the engagement itself. Participant response was overall positive and most felt that “just the right amount” of information was provided for the engagement.

Current Performance

In preparation for an open-ended probe designed to address their overall needs, customers were asked how satisfied they are with Hydro One’s overall performance. As in other research, most transmission customers are satisfied in this regard.

In response to an open-ended question to identify any needs that Hydro One may not be meeting, many customers did not provide any suggestions. However, those who did suggested Hydro One could improve in the areas of customer service, reliability and infrastructure. All suggested areas for improvement are included in Appendix 1.1.

Customer Outcomes

Hydro One and INNOVATIVE reviewed previously available documents and talked to customer-facing Hydro One staff in order to develop a list of customer outcomes that was included in the survey. Prior to being exposed to this list, an open-ended question designed to elicit outcomes in customers’ own words was asked. In response to this open-ended question, transmission customers said they know Hydro One is doing a good job for their business based on reliability, and customer service/communication (both of which were included in the list of outcomes developed for the survey). All outcomes suggested by transmission customers are included in Appendix 1.1.

Rating the provided list of seven customer outcomes on a scale of importance from 0 to 10 revealed that safety and reliability are top outcomes in terms of importance. When ranking in terms of what should be Hydro One’s first priority, safety and reliability once again appear at the top of the list. However, through the lens of a combined ranking (first, second, and third), reliability becomes the top priority followed by safety and outage restoration.

Pace of Investment

All business segments, particularly LDCs, prefer that investments be spread out over time, along with stable rate increases. This preference is due primarily to perceived affordability for ratepayers and the ability to plan ahead.

Executive Summary (2)

Reliability

In their own words, transmission customers define reliability using phrases like “lack of outages”, “stable power supply”, and “quality of power”. They also note that outages are not only a safety hazard, but also a financial concern affecting their business/production.

Reducing the frequency of power interruptions is more important than reducing the duration. Most important is reducing the number of day-to-day interruptions.

Illustrative Investment Scenarios

By a wide margin, maintaining the current level of investment (Scenario C) is the most popular choice over the other three scenarios. It is seen as reflective of the current approach which has the advantage of familiarity, and a less risky option. Second choice falls somewhere in between a decrease in investment (Scenario B) and maintaining the current level.

Differences Across Business Segments

Local Distribution Company (LDC) participants are less likely than End Users or Generators to consider reliability “extremely important”. Environmental stewardship is also less important among LDC customers than it is among the other Business Segments. On pace of investment, LDC customers show the strongest preference for spread-out investments and stable increases. Seventeen of 28 LDC customers prefer illustrative investment Scenario C (n=6) or an option one (n=6) or two (n=5) points lower along the spectrum (towards Scenario B).

About half of **End User** participants (19 of 38) rate power quality an “extremely important” outcome – a higher proportion than either LDC or Generator customers. End Users also consider productivity more important than the other business segments. While most (n=11) End Users selected illustrative investment Scenario C, they are also more likely than other business segments to have selected Scenario B (n=5).

Generator participants are most likely to consider safety an important outcome, with 30 of 35 rating it “extremely important”. This business segment also considers customer service to be more important than the other two business segments with about half rating it “extremely important”. Only among Generators does the level of support for illustrative investment Scenario D (n=6) approach the level of support for Scenario C (n=8).

Current Performance

Current Performance: Summary

Most transmission customers are satisfied with the overall performance of Hydro One in providing their business with electricity, suggesting that customer expectations are being met. That being said there are some End Users who report being “very dissatisfied” with Hydro One’s provision of electricity.

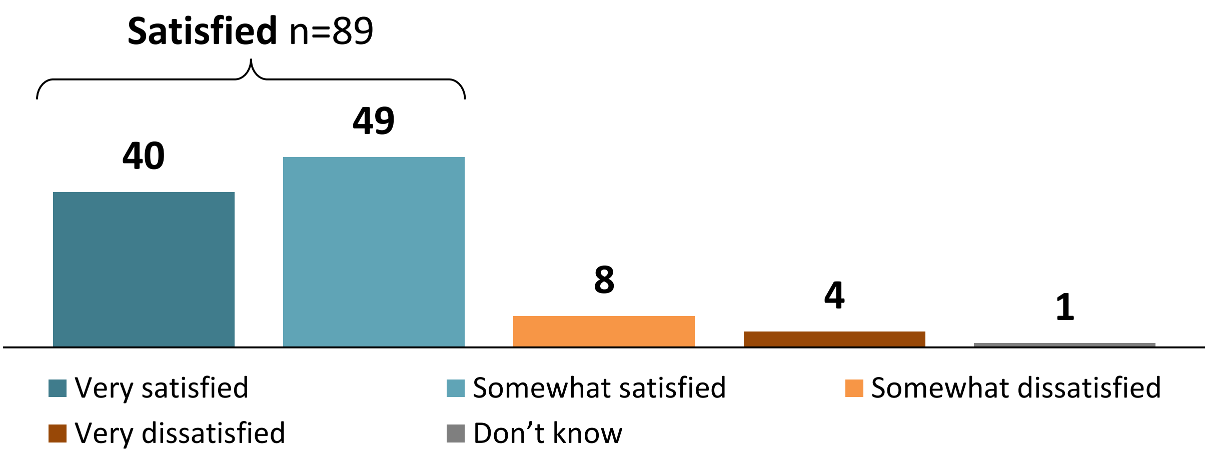
In response to an open-ended question, customers cite reliability and infrastructure concerns most frequently as outstanding needs. Reliability is mentioned most frequently by Generators and customers in the North. LDC customers are more likely than other business segments to mention infrastructure. Customers in the North and End Users do not mention improved communication in terms of outages, but LDCs and Generators in the rest of the province do. LDCs and those served by a Multi-Circuit connection are more likely than other segments to be looking for improved communication in general.

Overall Performance:

Across the board, most are satisfied with Hydro One's performance in providing their business with electricity

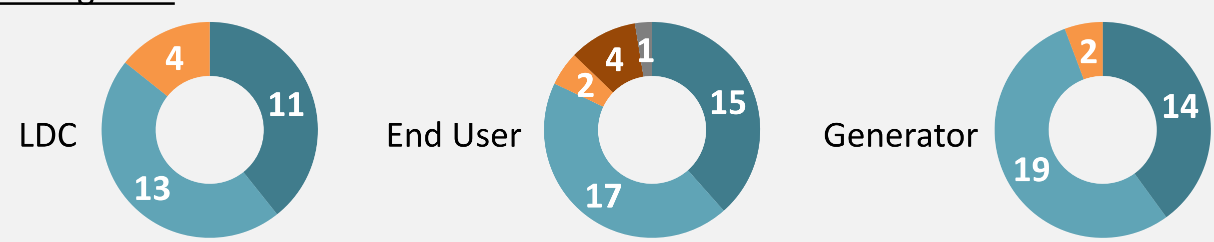
Q **How satisfied are you with the overall performance of Hydro One in providing your business with electricity?**

[asked of all respondents, n=103]

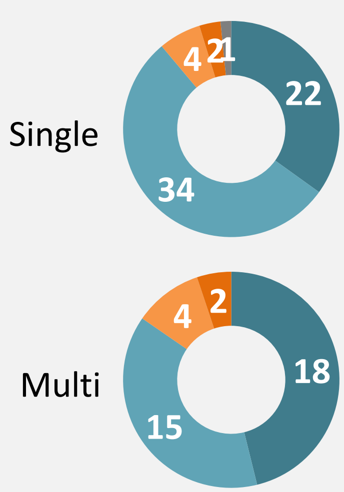


NOTE: No response (n=1) not shown

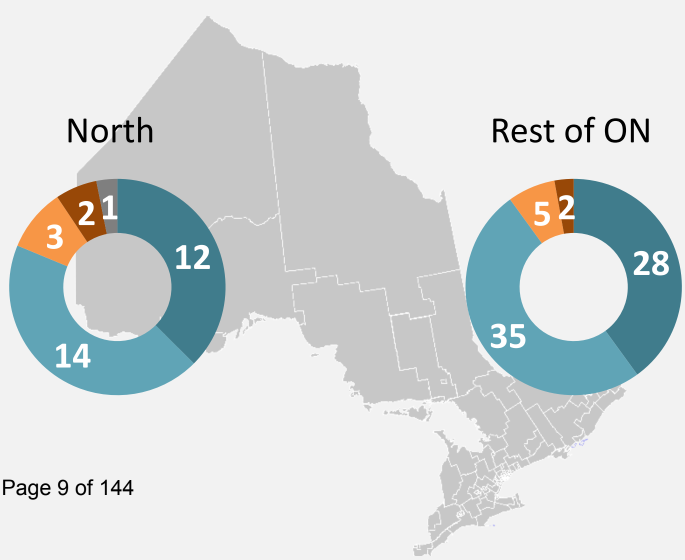
Business Segment



Single vs. Multi Circuit



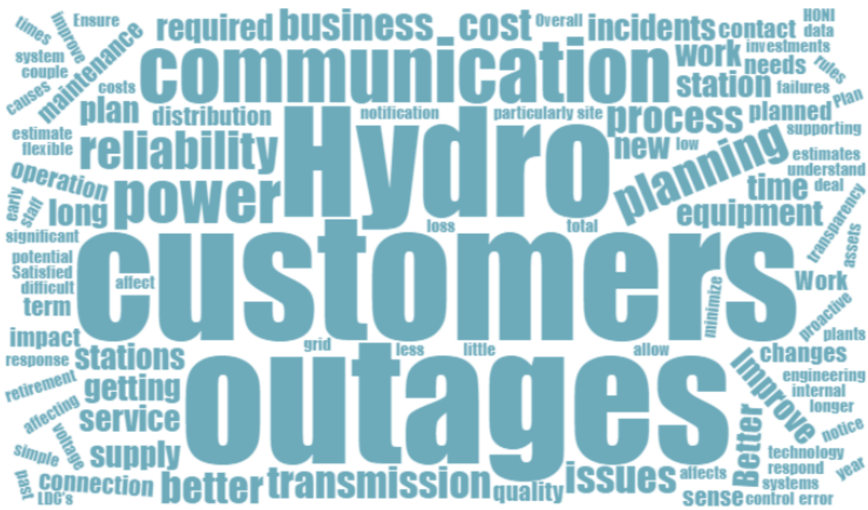
Region

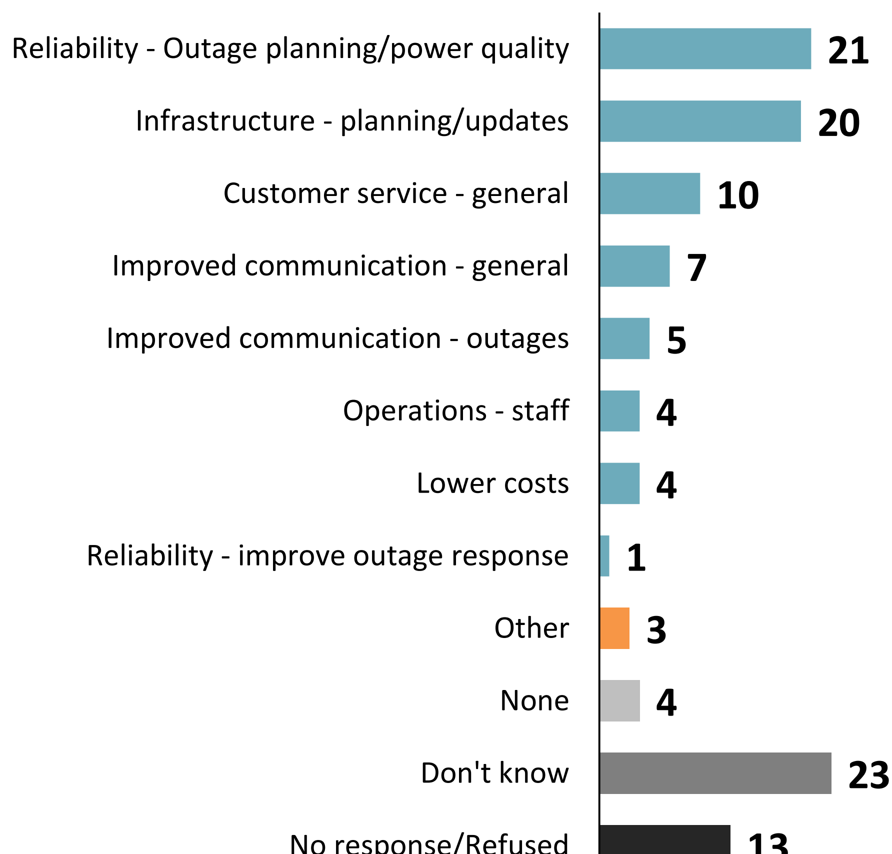


Suggestions for Improvement:

Reliability and *infrastructure* are top mentions

Is there anything in particular you feel Hydro One can do better?
[asked of all respondents, n=103]





INNOVATIVE RESEARCH GROUP

NOTE: Total is greater than 103 due to responses being coded into multiple categories

Suggestions for Improvement:
Verbatim for the top two responses

Reliability – Outage planning/power quality

- Address "power quality"
- be more reliable
- Better coordination of outages and associated changes to same which might affect generating stations on the same network.
- Coordinate planned maintenance outages - proper lengthy notice
- Decrease the number of outages
- More assistance with power quality investigations, especially where HONI customers are affecting our customers (i.e. HONI arc furnace customers causing voltage flicker issues for our customers)
- Plan HO outages during our low production times to limit the loss of revenue to our business
- Plan outages better and work in better with clients to minimize impact on their business
- Timely contact with Account Rep to review transmission system reliability and incidents affecting WNH
- Understanding the true meaning of reliability and the impacts this has not only on HO customers but the impacts this has on its neighbours.

Infrastructure – planning/updates

- Add capacitance on S2B line?
- Continue to maintain the distribution equipment.
- Earlier engagement with impacted LDC's for station asset renewal projects.
- Ensure reliability of supply by ensuring equipment supporting our plants is maintained to highest standard. Ensure management and training of staff supports safe and error free operation of equipment supporting our plants particularly the nuclear fleet.
- Estimation, planning and engineering could be more proactive with generators. A lot of delay in getting cost estimate and work planning are having huge impact on our business.
- I would like to see the long term plan for Hydro One transmission investments to see how it fits with our business requirements. I feel Transmission Station investments should be pooled to avoid duplication
- Improve Hydro One's procurement process to minimize delays in resolving equipment issues.
- Interaction between technical/engineering groups and customers early in the connection process needs to improve. Improved sense of accountability required at Hydro One. Actual connection costs coming in well outside acceptable industry variance ranges. Paying significant amounts for connection estimates that provide little value (+/-50% estimate is unacceptable from any engineering firm). No sense of urgency, unless the lights are out.
- Line Maintenance needs improvement due to two recent Sky wire failures.
- our response is transmission based only and does not include distribution supplied locations. Better notification and planning with regards to maintenance activities would allow us to better plan and respond to our down stream customers.
- Overall satisfied, however, some H1 assets are getting aged and maintenance times to return transformers back to service appear to be getting longer. Potential for future issues.
- Share long term plan and how it affects my site
- there have been some concerns expressed over voltage regulation and insulators failures at the ts.
- Timeliness of transmission station upgrades and renewal.
- Upgrade facilities to allow for simple transfer to alternate circuit in the event of work required on our circuit.

See Appendix 1.1 for all verbatim responses

Customer Outcomes

Customer Outcomes:
Developing the List of Outcomes

The Hydro One transmission customer engagement survey presented customers with a list of seven customer outcomes, which they were then asked to rate in terms of importance, and rank in terms of priority.

To develop this list of outcomes, we first conducted a review of existing research and other documentation, which included a study conducted by INNOVATIVE for the Canadian Electricity Association (Hydro One was a subscribing member for this research), Hydro One's strategic planning documents, a Transmission Customer Satisfaction Report written by Northstar in February of 2017, and a Transmission Customer Consultation Report prepared by Ipsos in April of 2016.

In addition to these materials, Hydro One senior representatives walked INNOVATIVE consultants through their internal planning process in order to explore how investment areas correspond to customer outcomes.

In order to ensure customer input was included in the development of the list of customer outcomes for the survey, a Hydro One senior executive conducted one-on-one interviews with customer-facing Hydro One staff. A summary of these interviews was shared with INNOVATIVE during the survey development phase.

Customer Outcomes: Summary

At the start of the survey, respondents were asked an open-ended question designed to elicit customer outcomes. Reliability - reduction of interruptions and good communication top the list of mentions. Looking at respondent segments, there are few differences, however, LDCs and those in the North are more likely to mention customer service in terms of availability than other customer segments.

Respondents were asked to rate seven customer outcomes on a scale of 0 (not at all important) to 10 (extremely important), and then to rank them in order of priority. The first exercise gives an idea of perceived importance of each individual outcome, while the ranking shows how customers perceive the outcomes in relation to each other. When asked to rate the *importance* of an outcome, safety and reliability receive the highest ratings. When asked to rank in order of *priority*, two stories emerge. Through the lens of first priority ranking, safety and reliability come out on top. When looking at the first, second, and third rank combined, a slightly different story appears. Reliability is ranked highest, followed by safety, and outage restoration becomes the third highest ranked outcome. Power quality and customer service land in the middle, and productivity and environmental stewardship are the bottom two.

At the overall level, 79 out of 103 survey participants rate safety “extremely important”. In fact, across all customer segments, most consider safety to be “extremely important”. Among Generators, there is not a single respondent who rates safety lower than a nine.

Reliability is second only to safety, with 71 of 103 rating it “extremely important”. Looking at the various customer segments, while there are some who rate reliability as low as a six, at least half consider reliability to be “extremely important”.

With 60 of 103 rating it “extremely important”, outage restoration rounds out the top three customer outcomes. In the North, no one rated outage restoration any lower than an eight, but in the rest of the province, a handful rated it seven or lower.

Fewer than half (44 of 103) rate power quality as “extremely important”. LDC customers do not give power quality a rating lower than a six, but there are customers in all other segments who consider power quality to rate somewhere between a zero and five on importance.

Looking at the bottom three, customer service is considered “extremely important” by 41 out of 103. Proportionately, Generators and transmission customers in the North are most likely to rate customer service a 10.

About a third (37 of 103) rate productivity at a 10. Generators do not rate productivity any lower than a six, but there is at least one customer in all other segments who rates it somewhere between a zero and five.

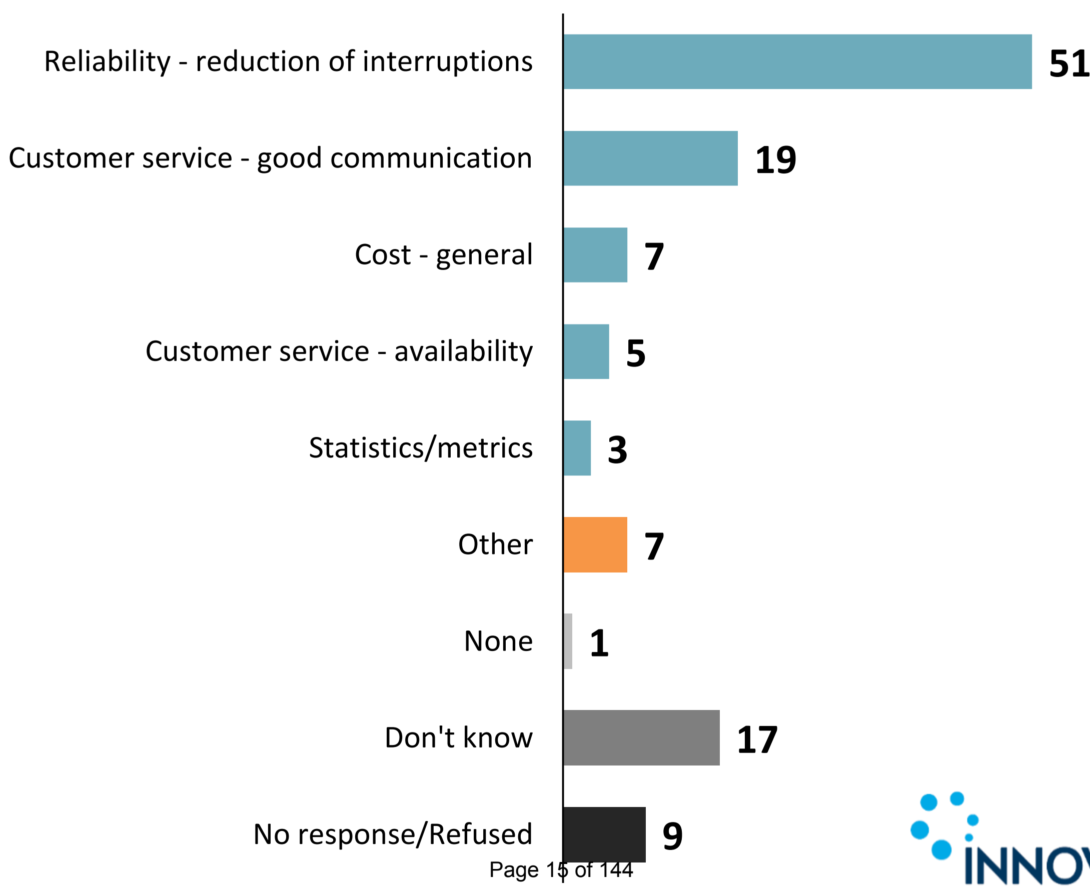
Rounding out the bottom three with 31 of 103 rating it “extremely important” is environmental stewardship. LDC customers tend to rate this outcome lower then End Users or Generators. Customers with a single-circuit connection consider it more important that those with a multi-circuit connection.

Asked if any customer outcomes were missing from the list of seven included in the survey, some customers were able to suggest additional customer outcomes, using phrases like “system capacity”, “value for money”, “response” and “customer service”. None of the suggested outcomes were ranked as being more of a priority than the original seven.

Performance Criteria:

Reduction in outages and interruptions, power supply, and customer service in terms of communication are top mentions for performance metrics

Q **How do you know if Hydro One is doing a good job for your business?**
[asked of all respondents, n=103]



INNOVATIVE RESEARCH GROUP

NOTE: Total is greater than 103 due to responses being coded into multiple categories

Performance Criteria:
Verbatim for the top response

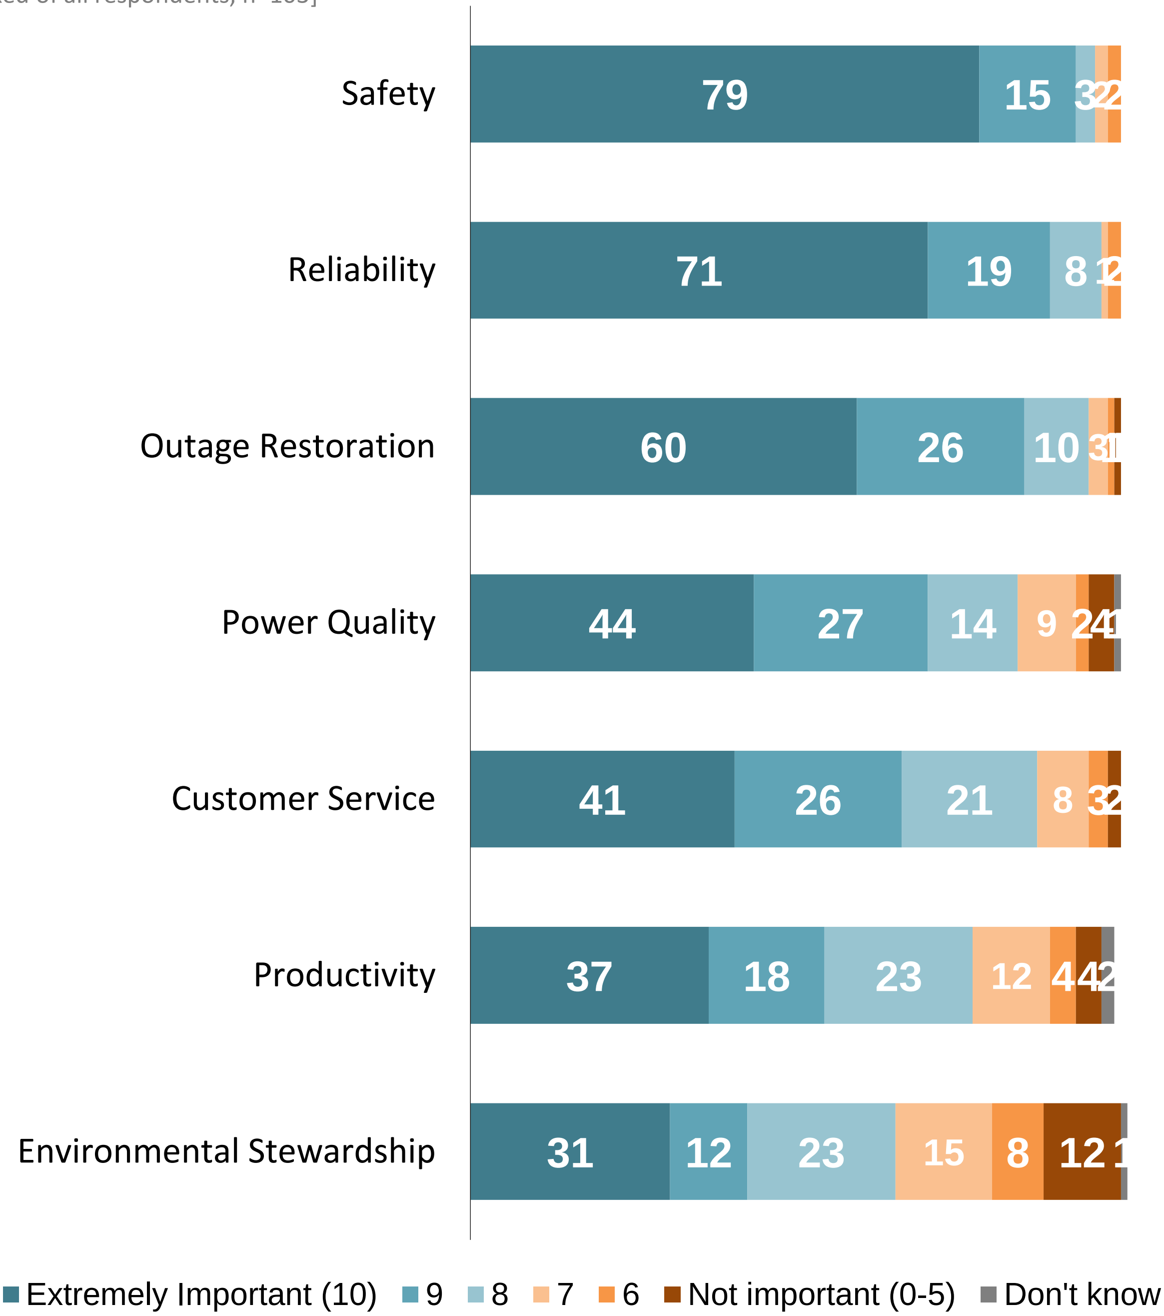
Reliability – reduction of interruptions

- if I do not have to call them
- Keeping the supply of power on
- My power is still on
- No surprises
- On rates, no idea...on work around transmission doing fine, meeting with us generators every 6 months to try and best facilitate outages/repairs/upgrades
- Performance is based on Hydro One's ability to provide its service reliably and implications to our operations.
- Power Supply reliability
- provides reliable supply and responsive service
- Reliability is important but at a cost that makes us uncompetitive and sends jobs abroad is not sustainable and will hurt all citizens of Ontario
- Reliability of supply.
- Reliable electrical power supply.
- reliable supply of electricity at a reasonable cost
- stable grid system, less impact on the customer side are all we need.
- that the delivery of Hydro is reliable
- They work with us in outage management
- Timely and accurate billing and reconciliation. Reliable power.
- We look at overall reliability as well as Hydro One's understanding and explanations of the incidents that have occurred.
- We measure reliability based on Loss of Supply. Quality and timeliness of responses from Distributed Generation and Engineering groups.
- When100% availability is achieved
- 1) No unplanned outages and consistent power quality. Score 8 out of 10. 2) Supportive in planning and outage response. Score 9 out of 10.
- By the way that Hydro One coordinates planned equipment outages with the customer needs.
- Effectively communicating and ensuring to work with customers to minimize impact of business interruption
- Electrical outages are rare and when there is an outage they are quick to respond and communicate the outage
- Few outages, either planned or unplanned
- Fewer outages
- Forced outages are reduced and power quality is improved.
- If the lines remain open for business and interruptions are held to a minimum
- If they are doing good then we won't have any surprise outages and/or time we can't inject into the grid.
- in simple terms as long as the electricity runs through the lines and there are no disturbances causing issues or damage to our equipment then everything is good
- Interruptions are at an absolute minimum and wherever possible with as much advance notice as possible.
- No interruptions in supply and no voltage issues.
- no issues with unplanned outages, invoices are accurate
- Number of outages my business experiences or individual equipment trips due to voltage sag
- Number of power interruptions that occur.
- Power reliability and quality issues reduce to once per year.
- Reliability and costs are the primary drivers in the measurement of performance.
- Reliability to date has been good, however, increasing frequency/duration of reduced redundancy due to extended maintenance periods. Resulting in higher potential risk exposure for customers.
- Reliability, costs, general customer service, responsiveness, operations service and interfaces, ease of doing business with, relationships. Enable the LDC to forward their objectives.
- Reliability, responsiveness
- Reliable service.
- Sustained, reliable electricity delivered to our door. Our joint work - when the actuals are more in line with the plan, be it outages or length of outages, and cost.
- Unplanned outages are minimal, good communication on maintenance being completed
- We are provided with the reliability information from our Network Management Officer.
- We can gage the performance of the HONI system via the number of outages due to loss of supply
- We seldom loose production because of hydro outages
- When I don't hear about any business interruptions or scheduling conflicts.

See Appendix 1.1 for all verbatim responses

Customer Outcomes:
Safety, reliability, and outage restoration are ranked as most important

Q How important an outcome is…
[asked of all respondents, n=103]

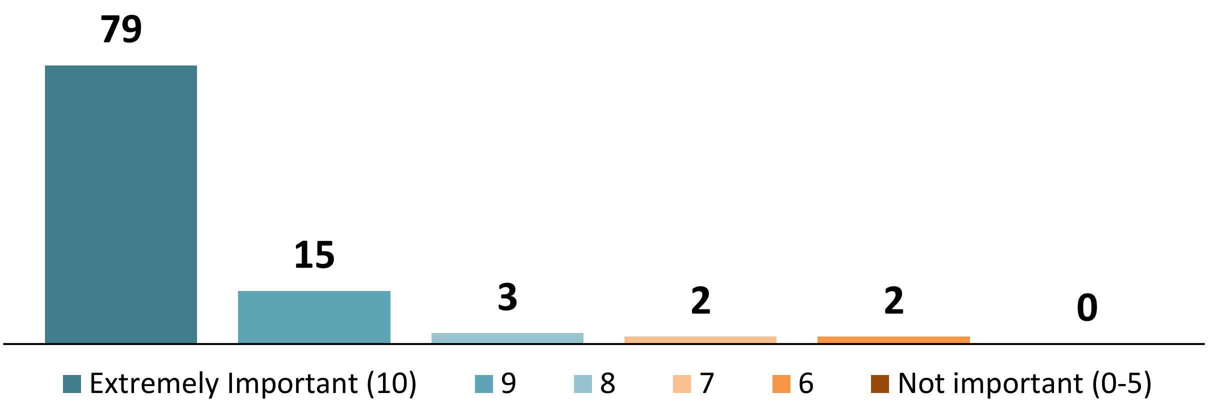


INNOVATIVE RESEARCH GROUP

NOTE: No response (n-size varies from 1 to 3) not shown

Safety:
Across all segments, most (n=79) consider safety to be extremely important

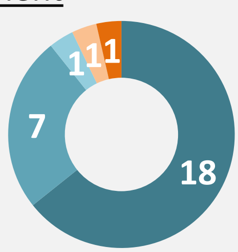
Q Eliminating and mitigating risk to public and employee safety in the operation of the transmission system. **How important an outcome is safety?**
[asked of all respondents, n=103]



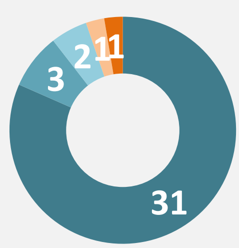
NOTE: No response (n=2) not shown

Business Segment

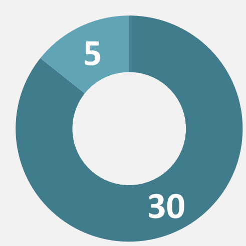
LDC



End User

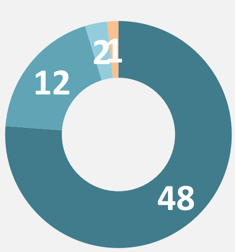


Generator

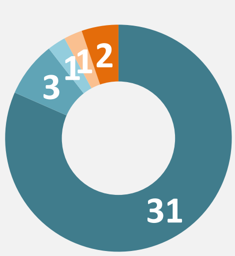


Single vs. Multi Circuit

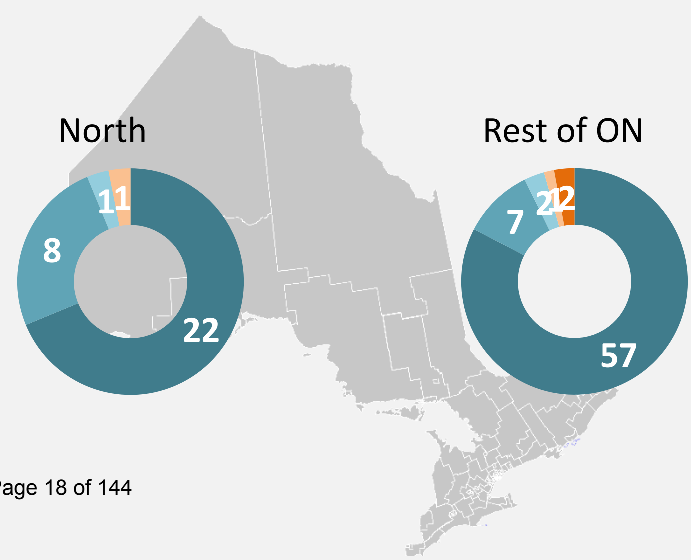
Single



Multi



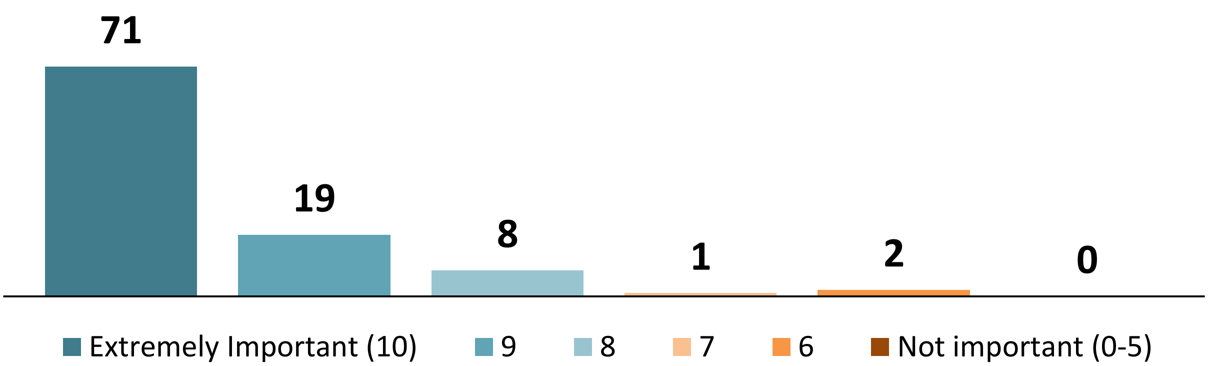
Region



Reliability:

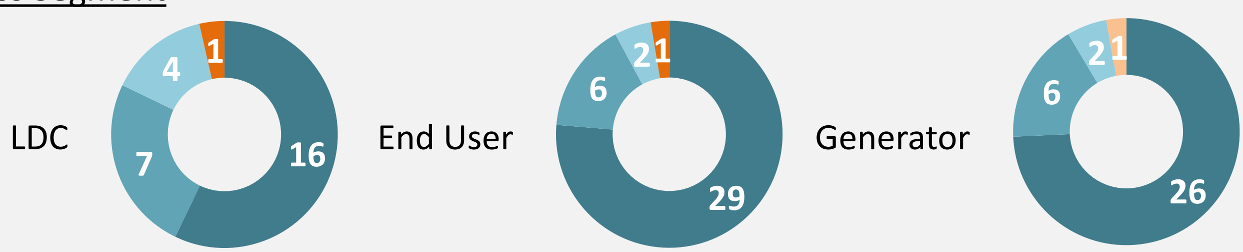
Most (n=71) consider reliability to be extremely important; LDCs are less likely than other business segment cohorts to consider reliability extremely important

Q Maintaining the uninterrupted operation of the transmission system for all customers by sustaining the existing assets, replacing assets that are in poor condition and addressing transmission system performance outliers. **How important an outcome is reliability?**
[asked of all respondents, n=103]

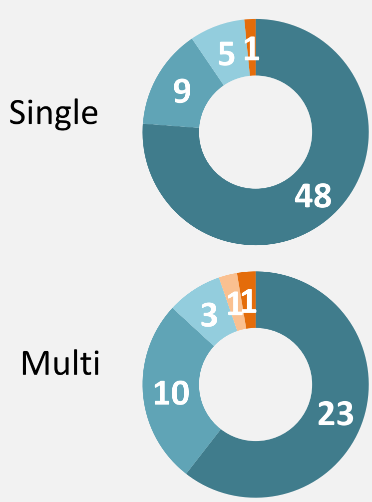


NOTE: No response (n=2) not shown

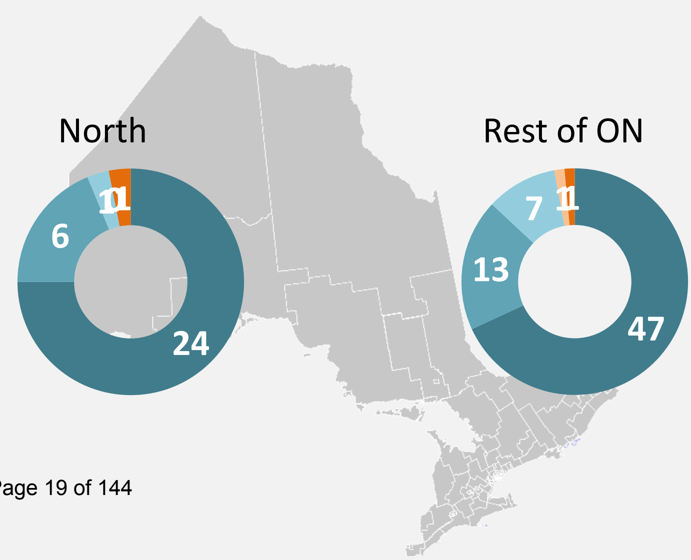
Business Segment



Single vs. Multi Circuit

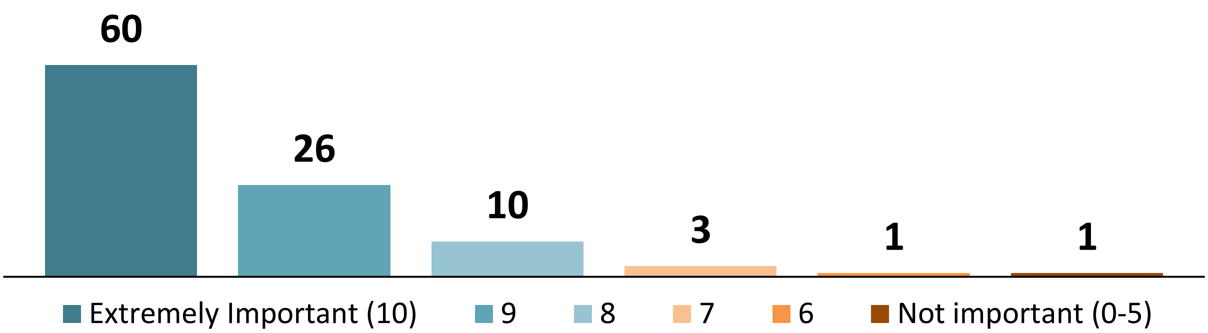


Region



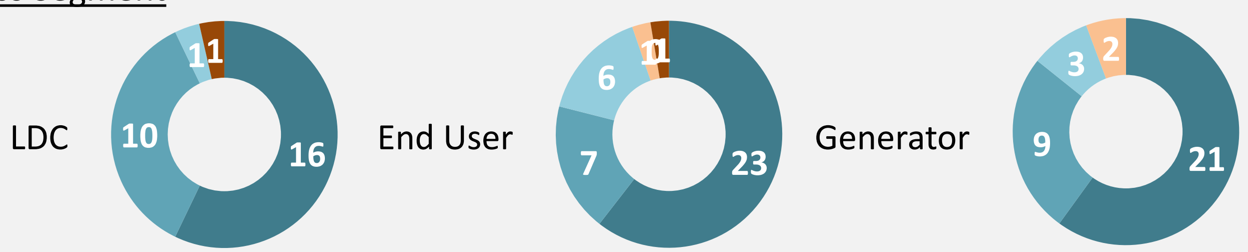
Outage Restoration:
Most (n=60) consider outage restoration extremely important; this opinion is strongest among Single Circuit transmission customers

Q Provisions to ensure timely and efficient response to failures, unplanned outages, or imminent risks to the transmission system to minimize customer interruption and prompt restoration to normal operating conditions. **How important an outcome is outage restoration?**
[asked of all respondents, n=103]

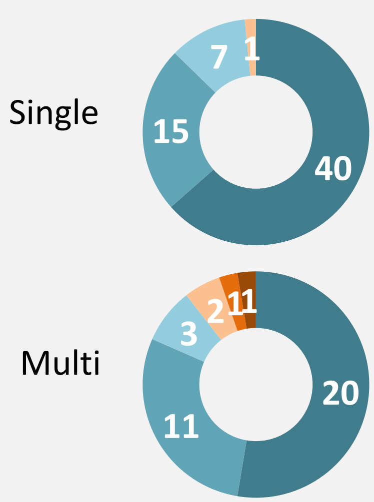


NOTE: No response (n=2) not shown

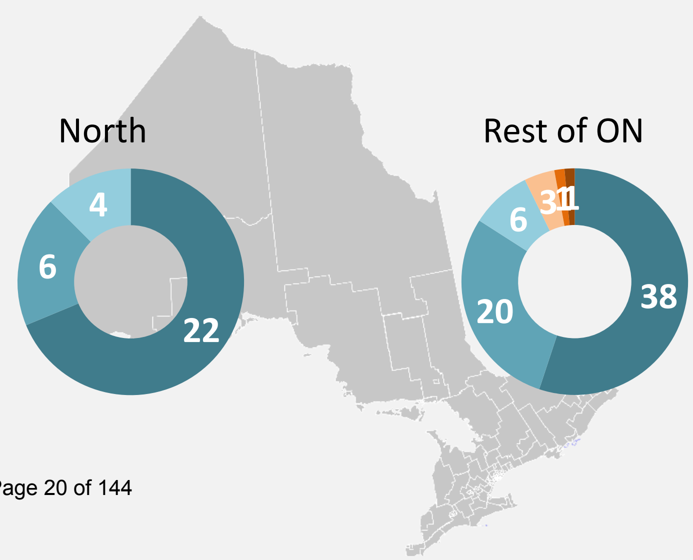
Business Segment



Single vs. Multi Circuit



Region

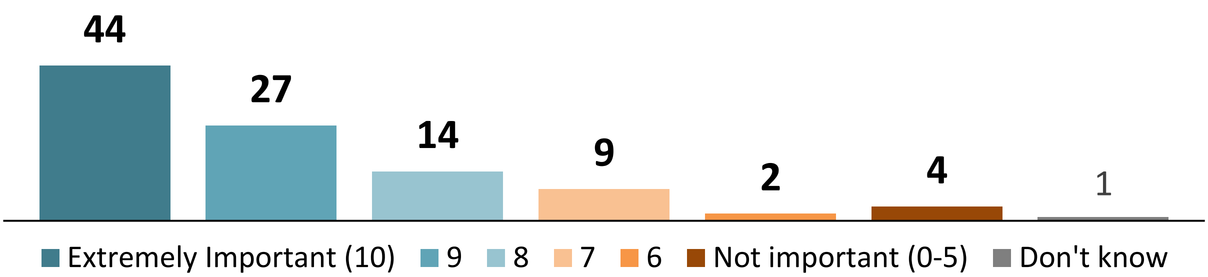


Power Quality:

A plurality perceive power quality as extremely important; this opinion is strongest among Single Circuit and End-User customers

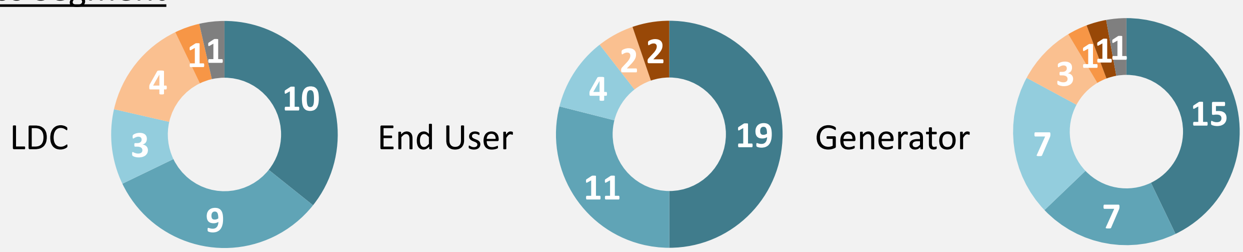
Q Delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform. Assessing customer concerns and implementing mitigation plans to address and rectify power quality issues for transmission connected customers. **How important an outcome is power quality?**

[asked of all respondents, n=103]

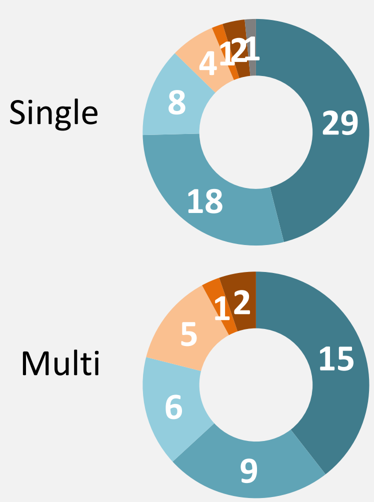


NOTE: No response (n=2) not shown

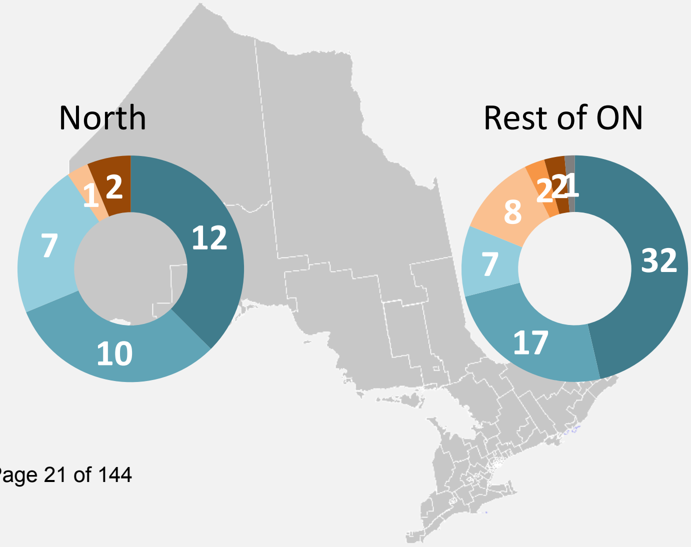
Business Segment



Single vs. Multi Circuit

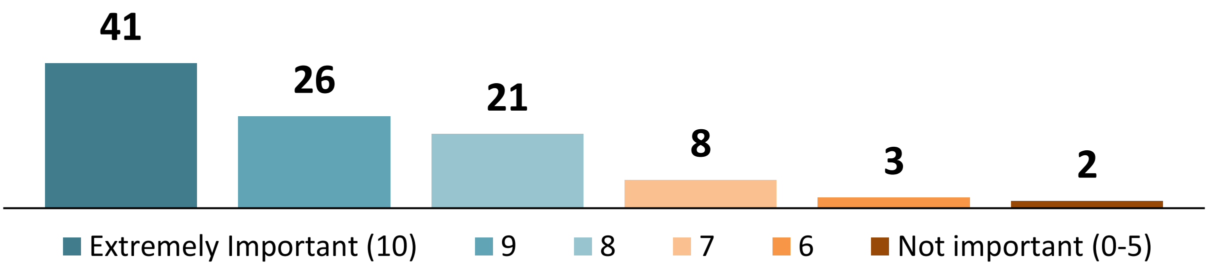


Region



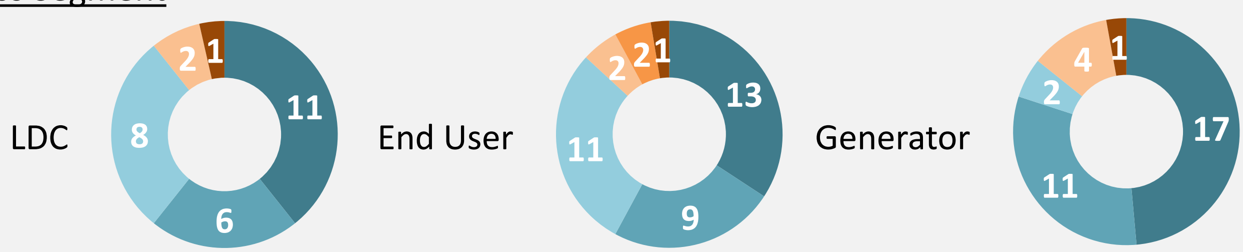
Customer Service:
A plurality (n=41) perceive customer service to be extremely important; this outcome is more likely to be of higher importance to those in the North region

Q Enhancements to the transmission customer experience such as outage planning and operational communications, timely estimates and project execution for transmission connected customers. **How important an outcome is customer service?**
[asked of all respondents, n=103]

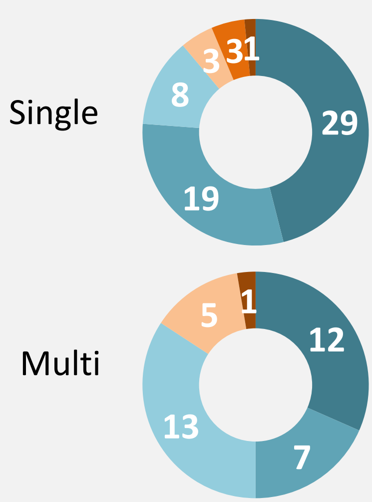


NOTE: No response (n=2) not shown

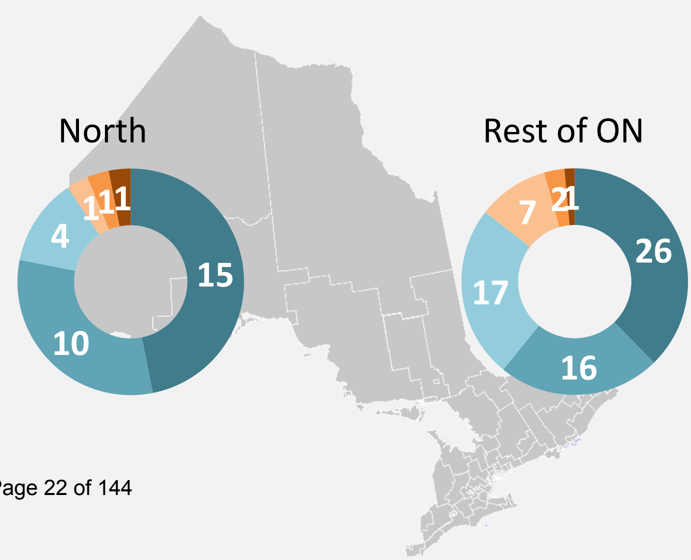
Business Segment



Single vs. Multi Circuit

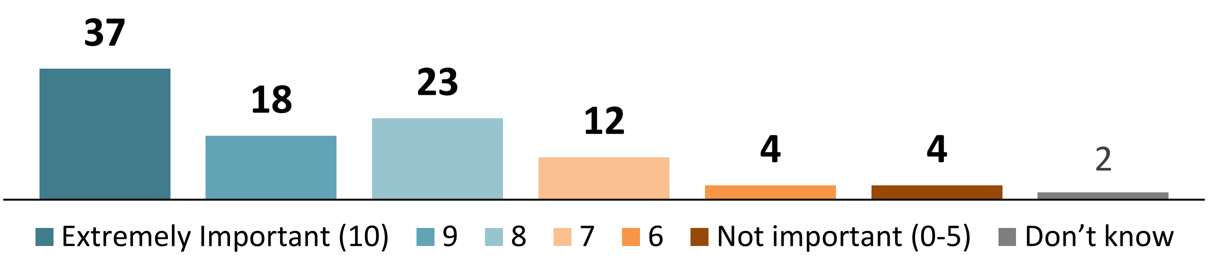


Region



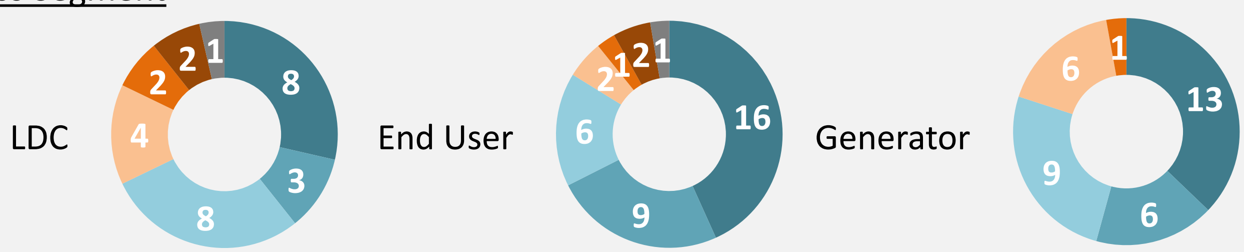
Productivity:
About half of End-Users say productivity is extremely important; importance of productivity is higher for the Single Circuit segment than Multi Circuit

Q Implementation of new technologies and processes to enable operational efficiencies in the planning and execution of work programs aimed at reducing costs and more efficient use of resources. Hydro One understands that customers expect it to look first for internal savings before asking for any additional rates. **How important an outcome is productivity?**
[asked of all respondents, n=103]

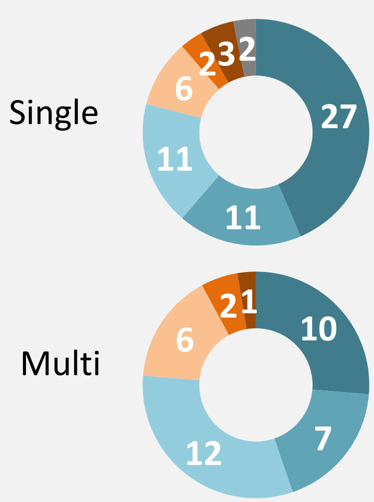


NOTE: No response (n=3) not shown

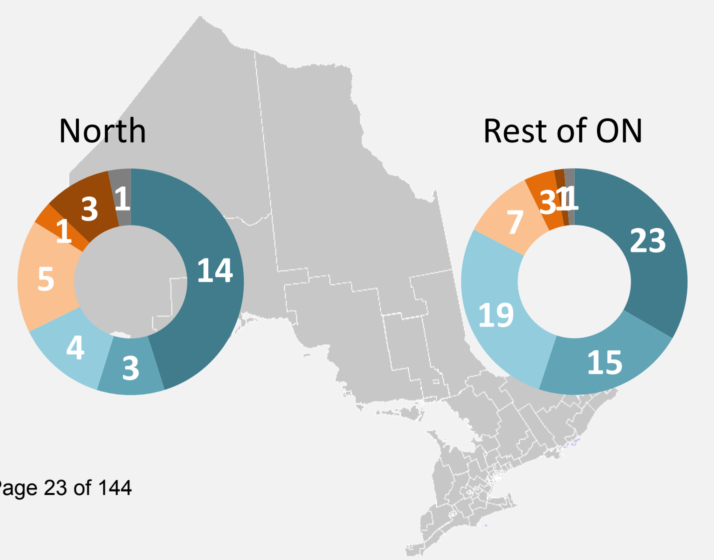
Business Segment



Single vs. Multi Circuit



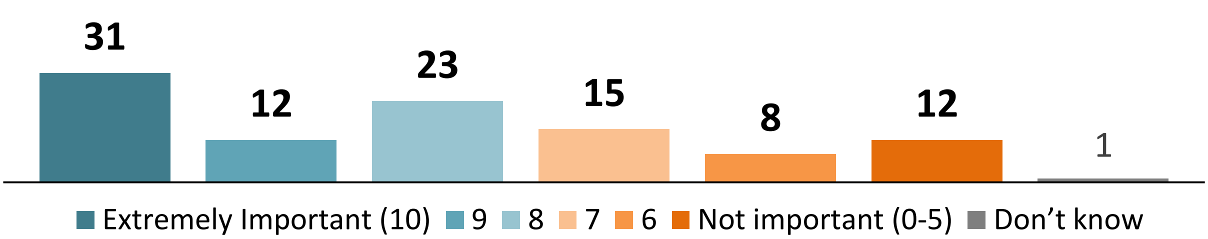
Region



Environmental Stewardship:

Importance of environmental stewardship is highest among the Single Circuit segment; least important among LDCs

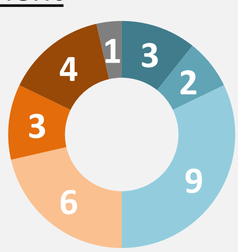
Q Identifying potential risks to the environment as a result of emissions from Hydro One's own operations, and investing in mitigation strategies to ensure compliance with all applicable environmental regulations consistent with the Government of Ontario and the Government of Canada. **How important an outcome is environmental stewardship?**
[asked of all respondents, n=103]



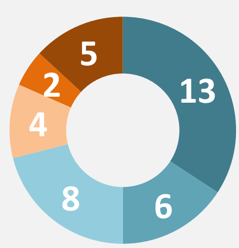
NOTE: No response (n=1) not shown

Business Segment

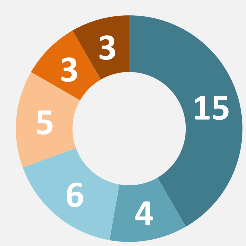
LDC



End User

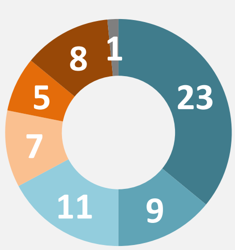


Generator

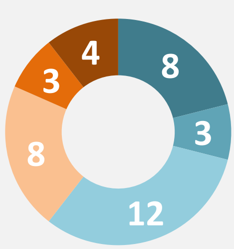


Single vs. Multi Circuit

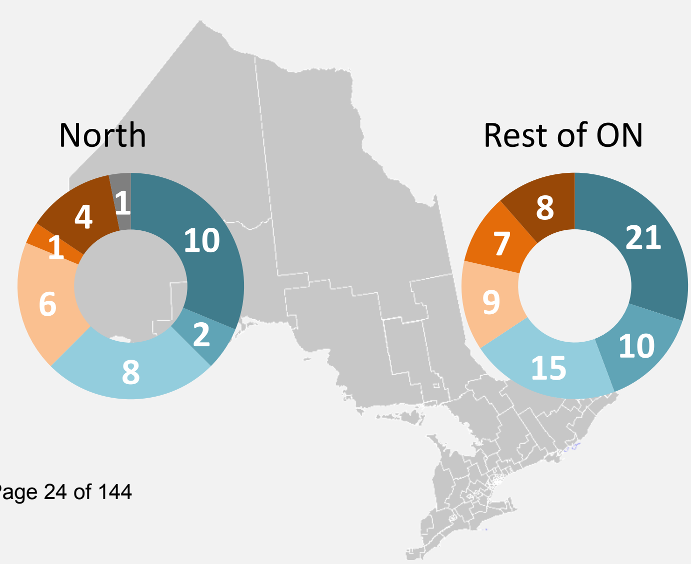
Single



Multi



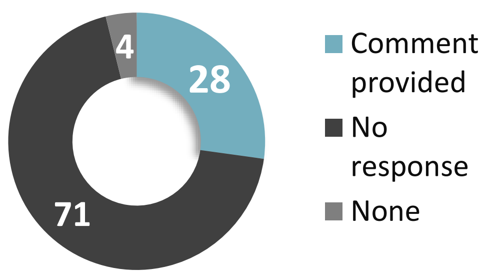
Region



Additional Outcomes (1):

Majority of respondents had nothing to offer on missed outcomes; among those who did, cost and capacity/expansion are top mentions

Q Are there any outcomes we missed? Please use the boxes below to add them, and then the slider to rate their importance.
[asked of all respondents, n=103]



System capacity - Have a transmission system with the capacity to meet the needs of our customers.

New connections and upgrades built and energized on a timely basis.

Price or cost - what is the value for money.

Costs; You will say its inferred in productivity and others. This is the reason we are in a mess.

Reduction on cost of GA.

Grid Capacity Expansion.

Response from local Hydro One team to respond to emergencies related to un-expected site power outage.

General communication about direction of HONI certainly helps me as a customer understand ramifications.

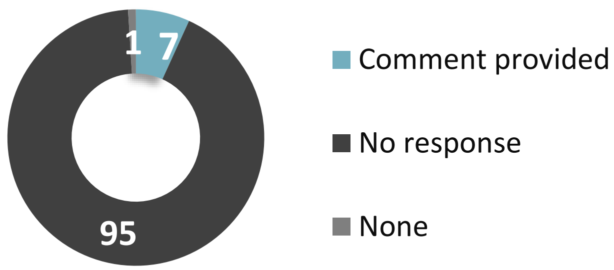
Responsiveness and personal assignment of a customer service representative for major customers.

Streamline the customer service experience to be able to reach appreciate parties efficiently.

INNOVATIVE RESEARCH GROUP

Additional Outcomes (2):
Very few were able to suggest a second additional outcome

Q Are there any outcomes we missed? Please use the boxes below to add them, and then the slider to rate their importance.
[asked of all respondents, n=103]



Reasonable cost and timeliness to provide services such as connections, transfer trips, CIAs.

Power Distribution costs go down.

Accountability and transparency - Most people can't understand their bills and costs are fixed.

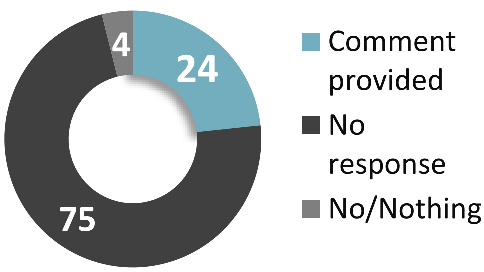
Drive for Delivery - accountable to deliver and action oriented.

Communication.

Comments:

Comments regarding customer outcomes touch on a wide variety of topics including safety, reliability, and cost

Q Do you have any specific comments or suggestions regarding any of the seven outcomes that you just rated or any additional outcomes you added?
Please fill in your response below.
[asked of all respondents, n=103]



Cost reductions should be a top priority and given serious consideration and not just lip service.

Cost estimates for work to be performed by Hydro One are extremely high. While part of the issue is the class C estimate contingency, those costs cause a lot of concern for customers considering connections for generators.

All outcomes are equally important. It is hard to have one and not the other. Ultimately we do not see the environmental stewardship piece directly at the mill site.

I like when you mention safety, the industry is very high risk and nice to see HONI as a leader.

The main outcome should be to provide reliable power at the best possible cost which should be benchmarked to a world standard to remain competitive and to make it so people don't have to choose between eating and having access to power.

As a generator it also extremely important that HONI is available to take the power and transmit it reliably.

Power Quality is an integral part of Reliability.

Ensure that there is regular communications and dialogue.

INNOVATIVE RESEARCH GROUP

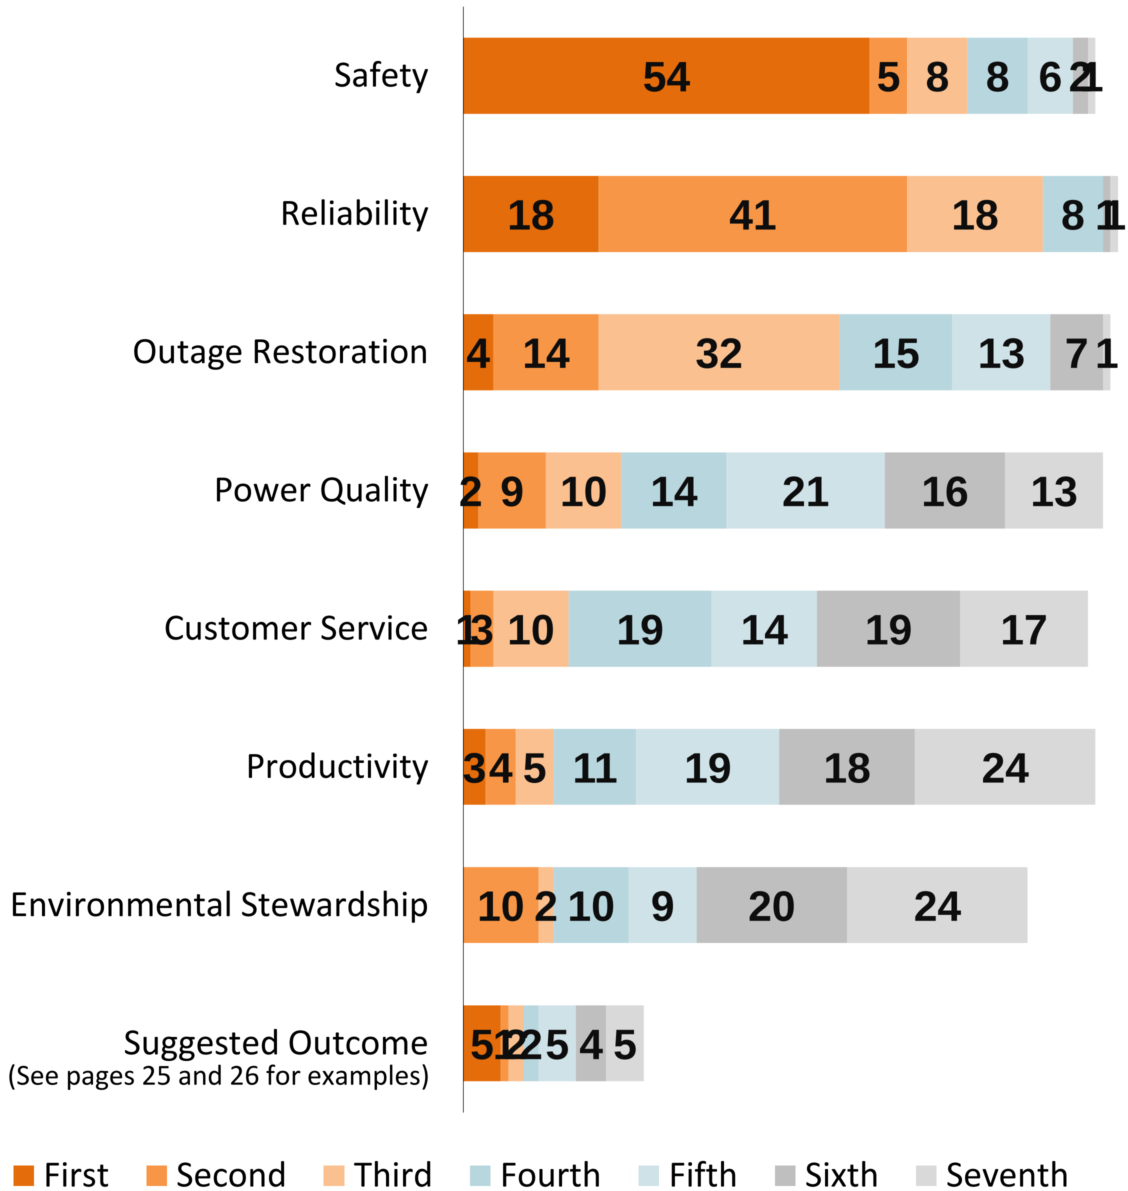
Top Priorities:

More than half rank safety as *first* priority. Rolling top 3 priorities together, reliability and outage restoration increase as priorities

Q While all the outcomes listed are important to many customers, planners set priorities among different outcomes. The purpose of this section is to help Hydro One set priorities as it prepares its business plan. Which priorities should they focus on first?

Please rank your top priorities from the list below.

[asked of all respondents, n=103]

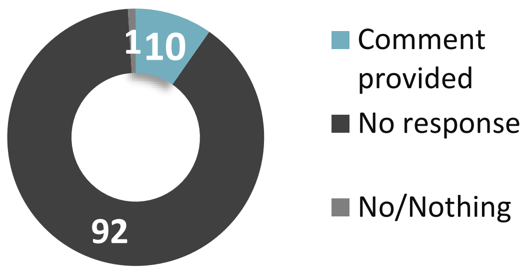


INNOVATIVE RESEARCH GROUP

NOTE: No response (n=16) not shown.

Comments:
Most did not provide any additional comments following the customer outcome priority ranking exercise

Q Comments in response to ranking customer outcome priorities:
[asked of all respondents, n=103]



Customer Service is affected by not only the customer service through communications and follow up but it is driven by the quality and reliability of the service of supplying electricity.

The focus on environmental steward ship and the solar and wind ventures it generated where ill conceived and poorly planned and have costs significant hardship on the citizens of Ontario . Although important it was very badly managed.

Note that although power quality is on the bottom it is also extremely important.

Safety and Environmental stewardship are not my interests but your employees and the governments interests respectively - as a customer I need performance improvement in all other areas and results now and need to know and trust that you have it and are going to do something on it.

As a customer, reliability and outage restoration are important outcomes. I should be able to rank those at the top without sacrificing Safety or the Environment. This survey does not give that choice.

Number one for my customers is rates. Productivity is not a direct reflection of that, but is similar.

This ranking is predicated on Hydro 1 executing these priorities - if power quality and reliability are not improved, then customer service becomes much more important.

This is difficult as they are all important.

INNOVATIVE RESEARCH GROUP

Pace of Investment

Pace of Investment: Summary

Customers indicate a strong preference for stable rate increases and investments spread out over time, with 74 out of 103 choosing this option over investing now (with higher rates in short term and lower future increases) or delaying investments (with lower rates in the short term and higher future increases).

LDCs show the strongest preference for spreading out investments, with all but a handful choosing this option.

Asked why they prefer this option over others, customers mention affordability and aligning rate increases with inflation. The perceived affordability of this option is viewed both from the perspective of being a business transmission customer (“Easier to forecast for business plan with stable increases”), as well as the end customer of LDCs (“This is the philosophy we have taken as a distributor ... affordability needs to be considered”).

Ten respondents were not able to make a choice on the pace of investment options presented to them. Some of these customers use phrases like “Show some flexibility” and “revisit and optimize costs” to describe what the decision depends on. Others wanted more detail about the investments and the magnitude of rate increases.

Pace of Investment:
Preamble and Survey Question

Before being asked the question about the pact of investment, respondents were provided with the following preamble:

When Hydro One replaces equipment in declining health, it has some flexibility in its pacing. We would like to understand your general views on the appropriate pacing of Hydro One's investments over the next 15 – 20 years. Hydro One can front load its capital investments, it can spread them evenly over time, or it can delay its investments.

Front-loading investments would provide some benefits in terms of more connection capacity, decreased equipment failures, increased reliability, and improved productivity and quality. This would mean higher rate increases now but lower rate increases in the future. Spreading evenly over time means some benefits are delayed but some long term savings are secured and it is more efficient in terms of staffing. Rate increases would increase at a stable level. Asset deployment costs would likely be lower using this more stable pacing philosophy.

Given the current health and demographics of the system, Hydro One can delay investments further until declining equipment conditions threaten Hydro One's ability to meet power reliability requirements. Reliability would still meet minimum standards but customers would likely experience more interruptions than today. Rates increases would be relatively low for several years but increase at a steeper rate in the future.

Following the preamble, respondents were asked the following question:

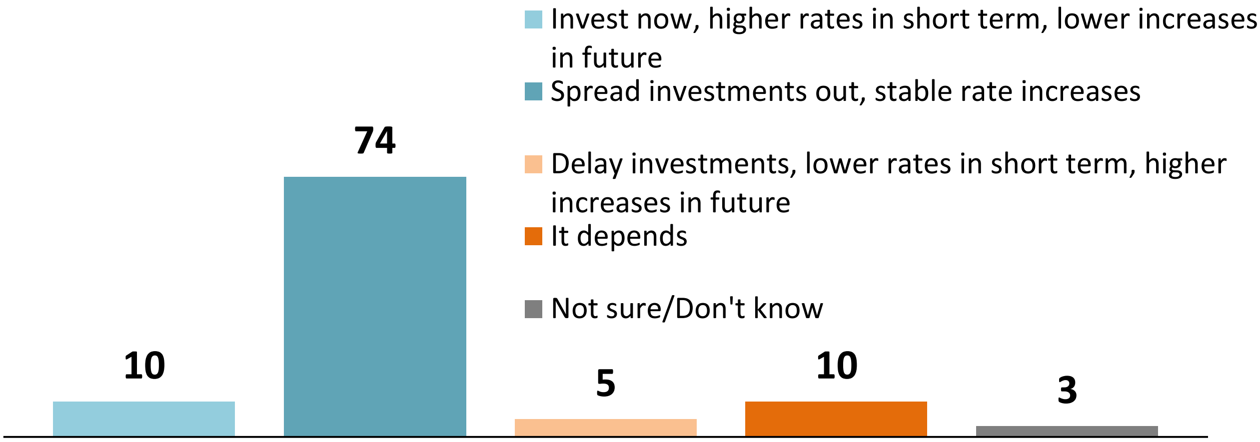
Bearing in mind the trade off between immediate rate impact, long term rate impacts and system benefits, which approach best reflects how you feel Hydro One should pace the work required to renew the system over the next 15-20 years?

Pace of Investment:

Strong preference for spread-out investments and stable increases; highest in 'Rest of Ontario' region and among Single Circuit customers

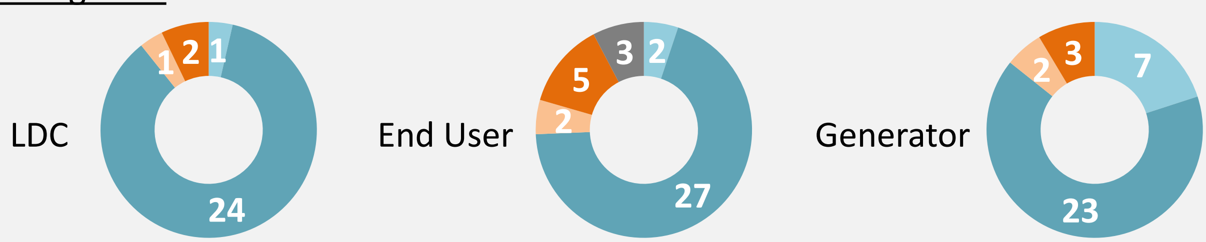
Q Bearing in mind the trade off between immediate rate impact, long term rate impacts and system benefits, which approach best reflects how you feel Hydro One should pace the work required to renew the system over the next 15-20 years?

[asked of all respondents, n=103]

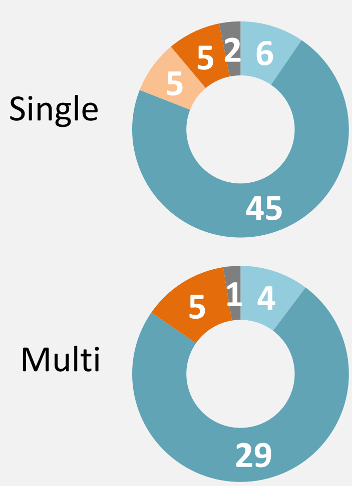


NOTE: No response (n=1) not shown

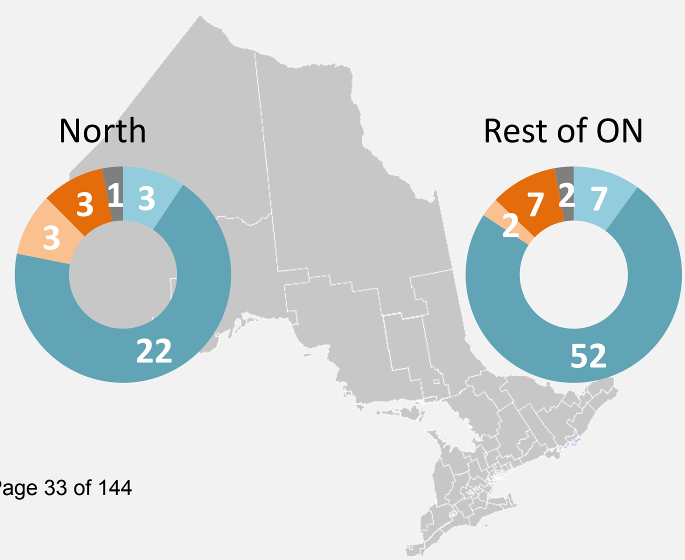
Business Segment



Single vs. Multi Circuit



Region



Invest Now:
Those who prefer to invest now appear to be motivated by the reliability risks associated with aging infrastructure

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

Invest now, higher rates in short term, lower increases in future…

Decrease in system reliability or increases in equipment failures negatively impacts our facilities operations and earnings.

Locally many assets are getting aged and reliability is already at risk. Higher capital investment now along with a push for higher productivity and lower internal cost would be the preferred approach to reduce rate impacts.

Infrastructure drives reliability.

Current state of equipment.

To increase capacity in the short term to be able to add more renewable energy to replace fossil and nuclear generation.

I say this but a change is an election away. We need the long term vision and goal the strive for.

Price only will go up if waiting.

INNOVATIVE RESEARCH GROUP

Spread Investments Out:

Preferences for spreading out investments seem to stem from themes of affordability and reducing financial impact for both rate payers and businesses

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

Spread investments out, stable rate increases…

Good balance.

Balanced investments so rate increases are aligned with inflation. Electricity in Ontario is extremely expensive and has put Ontario business at a significant disadvantage. While investments are necessary so are ensuring competitive costs.

Most cannot afford higher rates, and delaying will just cause future generations to deal with legacy issues.

This is the philosophy we have taken as a distributor. At some point affordability needs to be considered in capital expenditure levels year over year.

Would prefer option on invest now, but the cost may be too high, so spreading costs may be better.

Manageable to ratepayers while insuring reliability.

A spread of investments avoids putting costs to ratepayers in the future and avoids the risk that future ratepayers may be in a worse position to pay the increased rates. It also avoids the cost of frontloading the costs when there is currently much customer concern over their ability to pay. This middle alternative seems to provide a reasonable cost balance while somewhat increasing reliability risk.

Given that the current electricity rate in Ontario is among the highest in North America.

Financial impact.

Hydro is too expensive.

As a customer ourselves managing the rate increases so infrastructure investments are financed at a reasonable pace i.e. inflation plus 2%.

Less impact on cashflow for companies.

Easier to forecast for business plan with stable rate increases.

Produces more certainty in planning and rate increases.

Stable investments assuming reliability and PQ are held constant.

Over the long-term this provides the best return on investment.

INNOVATIVE RESEARCH GROUP

Spread Investments Out (2):

Spreading out investments can allow for reliability to be maintained while reducing financial impact

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

Spread investments out, stable rate increases…

It is unlikely that rates would ever decrease. Good practice would be to manage assets without too much of an impact on the customer and rates.

Spreading out investments allows you to prioritize as needed at a sustainable run rate, in addition to evening out the rate impact as much as possible.

I believe it's the best thing for the ratepayer. No shocks. I understand why Hydro One may see it differently, but the goal is to provide power with as much consistency in price as we can. Quick raises in price is not looked upon favourably.

Ontario residents are already suffering high energy costs.

Over half a century old, it's easier on the elderly population which is increasing to financially handle any smaller increases because of fixed income.

1) Predictability in pricing 2) Not letting the system fail

It is a reasonable approach between responding to excessive failures (by deferring investments) vs the additional cost (spreading the investment).

Preference is to have stable rate increases for financial planning provided that reliability is not compromised.

I believe that Hydro One can find internal efficiencies to help offset rates while continuing to improve reliability.

I don't believe delaying the investment would be prudent and we would feel that in the future with reliability and outage issues. I don't see our business expanding too much in the near future so I would prefer to spread it out evenly.

We cannot defer our costs to make the next generation can pay.

Its unfortunate the state of power in Ontario. Hydro One should reflect on their performance vs other provinces and states. What are we doing wrong when it costs so much to produce power vs other areas?

It's pragmatic.

INNOVATIVE RESEARCH GROUP

Delay Investments:
Finding internal efficiencies first is mentioned as rationale for delaying investments

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

Delay investments, lower rates in short term, higher increases in future…

Because I believe that internal productivity increases within Hydro One should be the first priority.

CUT COSTS NOW e.g. salaries by 15% to 30% for sunshine employees.

Hydro One needs to get their internal house in order before it inefficiency spends any more ratepayer dollars.

I don't agree it will mean higher increases in the future . AT least it may eliminate investments that are needed. We have made a lot of investments in the past we don't need. This will prevent that.

INNOVATIVE
RESEARCH GROUP

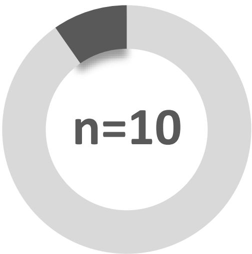
Pace of Investment (3):

Among those who say “It depends”, having flexibility in investment planning is a top concern

Q What does it depend on?

[asked of of those who said “it depends” when asked of about preferred paceof investment, n=10]

It depends



Customer connection requirements and timing of those. Show some flexibility! just because a new customer connection falls a year outside the Hydro One plan should not necessarily require the customer to pay the full advancement cost.

Plan the requirements, allow for the unexpected (which will be minimal if planned properly). Capital programs are inherently lumpy!

Safety, reliability, growth regions, new technology, innovation - it shouldn't just be an all or nothing approach.

It would have been useful if you could have quantified the magnitude of rate increases and not just higher or lower. Are you talking about 1 verses 2% or are you talking about 1 verses 10% It is hard to make a good decision until the impact is known.

Not knowing exactly what the investments are made to achieve/address and their impact/cost this question is difficult to answer in general.

I think you need to do some investments, spread payments over time, but revisit and optimize costs...ALWAYS be more productive, look for economies of scale, look to streamline and cut where people or assets are not productive and a drag on the system, literally and figuratively...have yet to see HONI do this.

A management plan that gets the most out of the team it has - I don't believe you have that yet.

Getting what you really need right (nowhere close to that yet), getting your operating costs in line (lots to do there), what your financing charges are compared to ours (we have to borrow to pay for you guys, and your rates are likely lower than ours), setting priorities that provide a level of priority for economic health of your jurisdiction vs convenience.

Reliability

Reliability: Summary

Asked what reliability means to their organization, for some customers, reliability is about having a power supply that is consistent and stable. For others, it is a lack of unplanned power interruptions. There are also some who emphasize the impact that power interruptions have on their business, both in terms of productivity and safety.

A consistent and stable power supply is mentioned more often by Generators and LDCs than End Users, and more often by Single-Circuit than Multi-Circuit customers.

Customers in the North mention no/few unplanned interruptions more often than customers elsewhere in the province, and End Users mention this more than LCDs or Generators.

When asked to rank five reliability metrics in terms of which are most important to them, transmission customers put reducing the frequency of day-to-day interruptions at the top of the list most frequently, followed by overall power quality and reducing the frequency of interruptions due to major events. Reducing the duration of interruptions (be they day-to-day or a result of major events) is less important than reducing the number of interruptions, when responses are ranked according to which is selected most often as a “first priority”, but when first, second and third priorities are added together, reducing the duration of day-to-day interruptions is almost on par with reducing the number of interruptions due to major events.

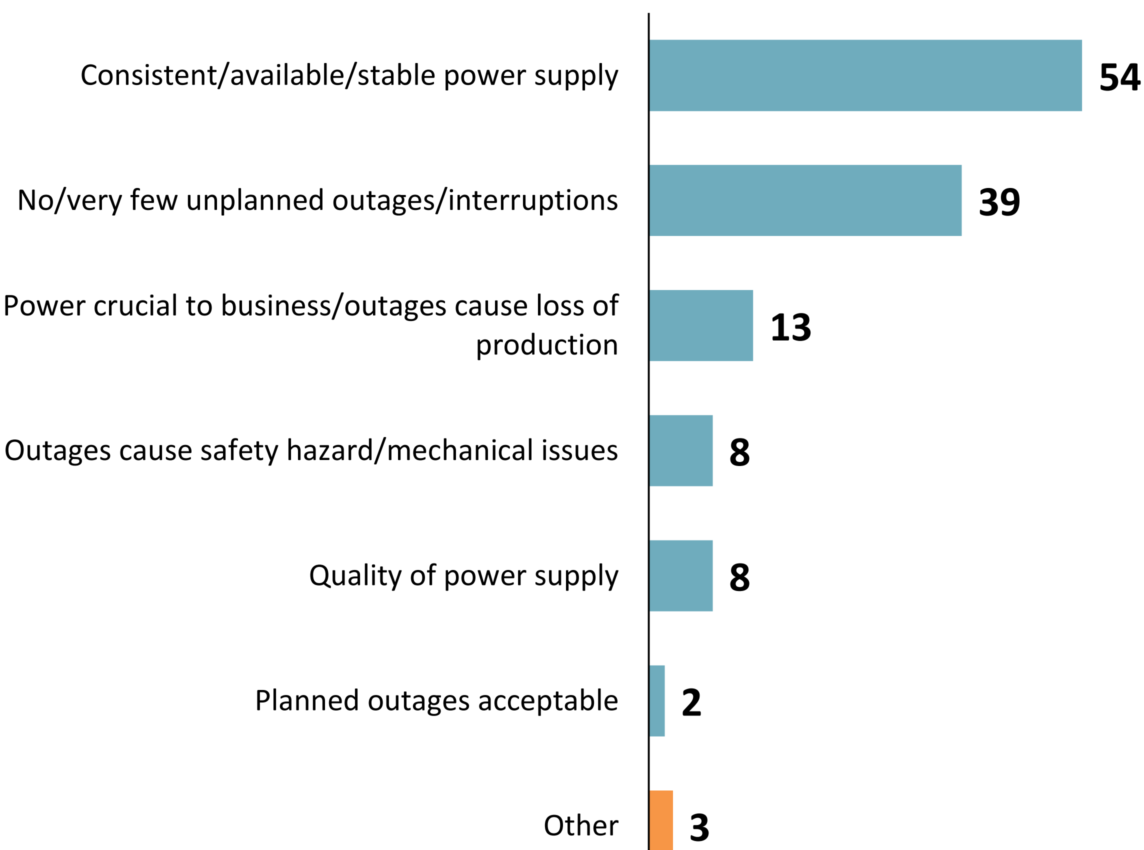
Customers were provided with a comments box in which to record anything they wanted to add on the topic of reliability. Sixteen customers recorded comments, ranging from not being able to control major events to feeling that power quality did not belong on the list as it is not a transmission issue.

Reliability:

Availability, consistent supply, and lack of outages are the phrases used most often by customers to define reliability

Q We are now going to move on to the topic of reliability. The term "reliability" means different things to different people, so before we move on, please describe what reliability means to your organization. When you are talking about transmission reliability, what does that mean to your organization?

[asked of all respondents, n=103]



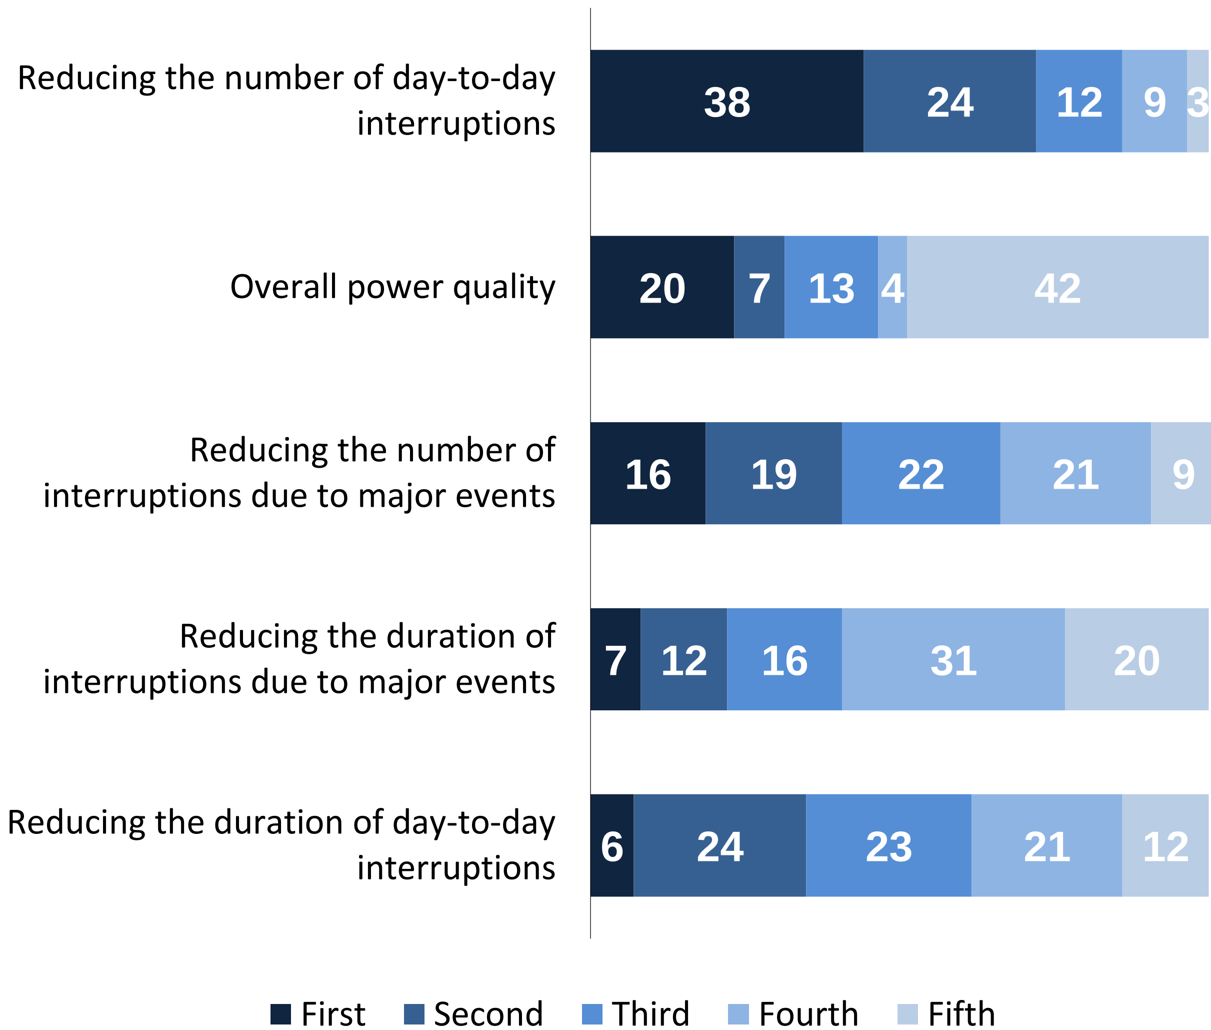
NOTE: Total is greater than 103 due to responses being coded into multiple categories

Reliability Priorities:

Reducing interruption frequency appears to be more important than reducing interruption duration

Q Reliability has a specific meaning in electricity, but often when customers talk about reliability, they are also talking about power quality (defined as delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform). Below is a list of five items that are often included when people talk about reliability. In addition to power quality, when people raise concerns about interruptions they often draw a distinction between interruptions that are experienced during normal day-to-day operations versus interruptions that occur during major events such as severe storms. **Please rank the following reliability items in order of which are most important to your organization.**

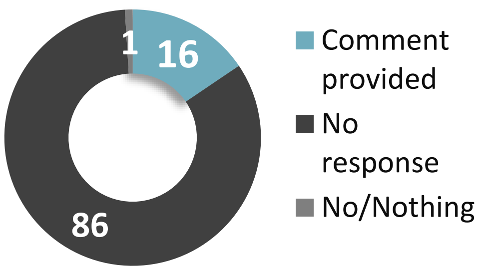
[asked of all respondents, n=103]

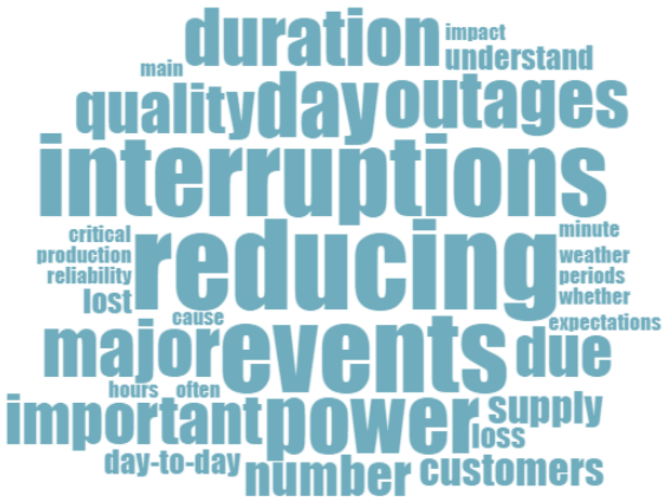


NOTE: No response (n=16 for first priority, n=17 for additional priorities) not shown.

Comments on Reliability:
Focus on reducing day-to-day interruptions over unpredictable major events

Q Is there anything else you would like to add on the topic of reliability?
[asked of all respondents, n=103]





I understand we do not control the weather, goal is to reduce the impact on the utility.

Major events cannot be reasonably predicted especially with global warming trends and more severe weather. The flexibility and the ability to react to the event is more important which will impact duration.

Power quality is most important to large, power quality sensitive customers while small commercial or residential customers are most concerned with the number and duration of day-to-day interruptions. Most customers have the most tolerance for outages due to major events as they can understand the reason behind the outage while the cause of day to day outages is largely invisible to most customers.

Power quality is not a transmission issue and shouldn't be on the list. Frequency and duration of outages are the key. Due planning processes for planned events is critical.

On-peak periods is our main focus and need interruptions reduced or eliminated during the on-peak periods Monday thru Friday.

INNOVATIVE RESEARCH GROUP

Investment Scenarios

hydro one

Investment Scenarios: Summary

Respondents were provided with detailed descriptions of four illustrative investment scenarios. These scenarios were then plotted as reference points along a line of 17 points, and respondents were asked to choose a point along that line which best represented their preferred approach for Hydro One's investments (see page 22 of Appendix 1.2). Scenario A was based on limited investment, Scenario B involved a decrease in the current level of investment, Scenario C would maintain the current level of investment, and Scenario D would increase beyond the current level of investment. Each scenario impacts reliability risk, long-term reliability and future rates.

Scenario C, which maintains current investment, decreases reliability risk, increases long-term reliability and offers level future rate increases was the single most popular choice with 25 out of 103 survey respondents selecting this option. Having the ability to choose one of 17 points along a line, 22 chose a point between Scenario B and Scenario C, and 18 chose a point between Scenario C and Scenario D. This clustering of points around Scenario C reinforces the earlier stated preference for a pace of investment which would spread investments out over time with stable rate increases.

This pattern of "clustering" on or near the point along the line representing Scenario C was common across all business segments. Generators are the only business segment where the level of support for Scenario D (n=6) approaches the level of support for Scenario C (n=8).

All respondents were asked to describe why they chose the point along the line that they did. Those who chose Scenario C used phrases like "reduces risk", "maintaining status quo would seem appropriate", "balanced and consistent", and "same health level as it is today".

Illustrative Scenarios:
Information for Participants

A preamble provided background on four illustrative investment scenarios. Each scenario was then described in detail, and a summary table (below) provided a comparative overview of all four scenarios. The descriptions of the illustrative investment scenarios can be found on pages 18 to 22 of Appendix 1.2, and a slightly more detailed summary table was available to survey participants on page 18 of Appendix 1.3.

	Illustrative Scenarios			
	A: Limited investment	**B: Decrease in current level of investment**	**C: Maintain current level of investment**	**D: Increase beyond the current level of investment**
5 Year Capital Investment	$1.8 B	$4.3 B	$6.6 B	$7.4 B
Reliability Risk	Increase in risk ~30%	Increase in risk ~10%	Decrease in risk ~10%	Decrease in risk ~15%
Long-term Reliability Impact	↓	↓	↑	↑*
Average Percentage of Key Assets Beyond Expected Service Life by end of 2023 (21% in 2019)	29%	26%	19%	17%
Impact on Future rates	Significantly higher future rate increases	Higher future rate increases	Level future rate increases.	Slightly lower future rate increases.
Average Annual Total Bill Impact – Transmission Connected Customer	0.11%	0.27%	0.42%	0.46%
Average Annual Transmission Rate Increase	1.30%	3.30%	5.10%	5.60%

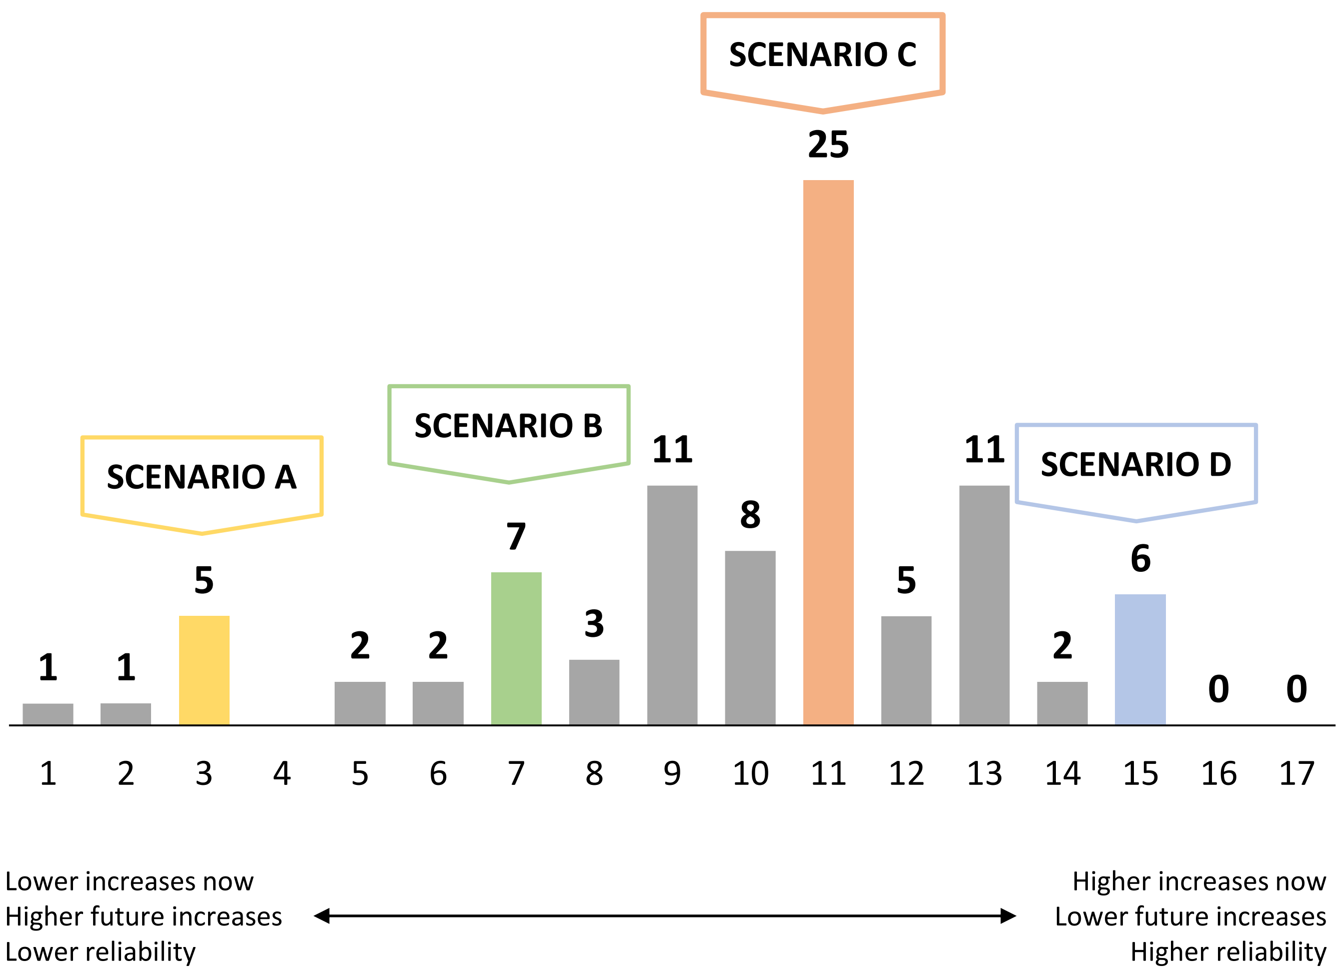
* Improvement in overall long term reliability and significant performance improvement for small number of customers connected to the worst performing circuits.

INNOVATIVE RESEARCH GROUP

Illustrative Scenarios:

Maintaining current level of investment ("Scenario C") is the most popular scenario

Q Thinking of all the considerations outlined, please choose a point along the line below that you believe strikes the right balance between rates and outcomes. (Remember that you can choose a point between scenarios or directly aligned with one of them).
[asked of all respondents, n=103]

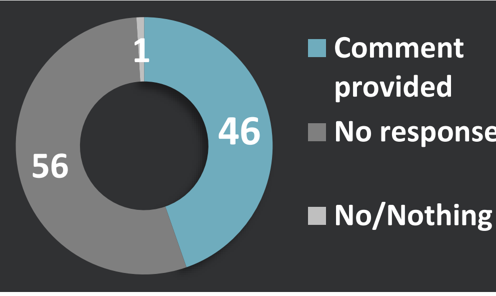


NOTE: "Don't know" (n=7), No response (n=7) not shown.

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
LDC		1	1		1	1			5	6	6	1	3				
End-User			2		1		5	1	3	2	11	2	4				
Generator	1		2			1	2	2	3		8	2	4	2	6		

Comments:

Point 3 - “Scenario A” preferred by those who want to limit rate increases



Please use this space to tell us why you chose the point you did.
[asked of all respondents, n=103]

Point 1

Clever OEB type presentation Ontario in very fragile economic condition   Just focus on cutting cost There is not as you imply direct correlation between cost reduction and reliability.

Point 2

1) Hydro One is inefficient and needs to sort out their internal processes and find greater efficiency. 2) There is nothing in this plan for innovation. Why would they invest in Tx infrastructure without a plan to manage the two-way flow of electricity that distributed generation will bring in 10-15 years. The last thing anyone wants is billions of $ in distressed.

Point 3 – “Scenario A”

I am prepared to take on more risk as we get the cost envelope sorted out and I am not willing to accept that rates would only change from .11% to .46% between scenario's when costs to the public have been going up by double digits per year for many years. In addition I am not prepared to accept that managing the rate of investment now will necessarily result in significantly higher future rates. The whole system has to take responsibility for the costs the public is struggling with NOW!

Scenario A seems the most favourable at this time; companies are very cost focussed and margins are currently very tight.

Low rates a priority and managed risks - information is imperfect and so the best investment is to get better data/information while you have the time to drive better investment outcomes while living within a cost affordability index. Are you getting the right bang for your investment today? That data was not made available - can you assume you will get more for the money you are investing?

Point 4 – No comments

Point 5

Keep increases at inflation.

Point 6

You should manage your business to be at or below the annual Canadian index price increase and still be reliable. Actual rates are already very high. We pay anywhere between $120-150/MW which is too high.

I recognize HONI has very difficult choices to make. However, it is very difficult to support a transmission rate increase that is greater than 1.5 times CPI

Comments (2):

Point 7 – "Scenario B" preferred by those who acknowledge the current state of rates

Q Please use this space to tell us why you chose the point you did.
[asked of all respondents, n=103]

Point 7 – "Scenario B"

Hydro One is unfortunately operating in one of the highest rate markets in North America. Normally higher increases could be tolerated, however with the current state of the electricity market reasonable rate increase are expected, even if it comes at the cost of degraded reliability. This is ultimately due to current and previous provincial governments however Hydro One is forced to take this under consideration.

We're on unreliable lines so we'd like some investment in those lines under any scenario. some is more than what we've seen in recent years. with upward pressure on rates, we'd be hard pressed to call for much more reinvestment than B.   I'm wondering about the capital estimates and whether or not there is any room for efficiencies within?

Balance the annual rate increase based on risk.

Point 8

Transmission costs are already too high. More needs to be done to ensure the investment $$ are being spent wisely.

INNOVATIVE RESEARCH GROUP

Comments (3):
Point 9 preferred by those who are looking for a balance between improving reliability and the cost of doing so

Q Please use this space to tell us why you chose the point you did.
[asked of all respondents, n=103]

Point 9

Best balance of costs vs benefits.

Chose the middle, trying to find a happy medium, so that we try to fix the mess we are in efficiently and cost affective as possible. However the rate increases is to high but we can't keep delaying either creating a bigger problem for future etc.

Reliability needs to improve but rate increases need to be balanced as it effects our operating costs.

We want a decrease in reliability risk and not too much increase in rates.

I do not agree with Hydro One's premise that there should be increases in Hydro rates amongst all the options. Like any other business; Hydro One needs to improve how it runs its business; how it seeks innovative answers; how it can deliver the same or better service for less money. I fundamentally disagree with all the options above; Hydro One has to stop acting in a way that it think it is entitled to more money or else the lights go out; Hydro One needs to start thinking like all other businesses; get lean; lower costs; meet customer expectations. The people and businesses of Ontario shouldn't have to keep paying for Hydro One's excesses. Rates should be kept constant; and the service should improve for that cost moving forward.

Preference would be investment close to scenario C but at lower transmission rate increase. i.e. Hydro One should look into improving its own efficiencies or finding ways to obtain the required funds to achieve scenario D or at minimum Scenario C's goals without significant increases to the transmission rates.

Significant investments have been made over the last five years to allow for DG resources to be connected. My expectation is that the rate of investment can now be curtailed back some.

INNOVATIVE RESEARCH GROUP

Comments (4):
Point 11 - “Scenario C” as a reference point is the most popular choice

Q Please use this space to tell us why you chose the point you did.
[asked of all respondents, n=103]

Point 10

The costs are a major input into these evaluations. A TS decommissioning was quoted at over $10M, transfer trip for a DG a few years ago was $180k is now being quoted at $400k, rebuilding a TS is being quoted at $38M. The choice is really C with an A rate increase.

Internal savings and efficiencies must be considered (salaries) to minimize rate increases. Increases in the 2 to 3% range combined with internal savings should net to Scenario C. This should be the goal.

This rate should still enable you to decrease the risk without a significant short term rate increase.

Maintains the average percentage of key assets beyond expected service life constant.

Point 11 – “Scenario C”

Do not want to see any service supply or reliability deteriorate from the current state.

Increased reliability, levelled rates.

It combines all four scenarios into one with moderate rate increase, high reliability and moderature future increases.

It meets many of the things and it's a substantial capital investment, but it has a lot of things moving in the right way. Decrease in reliability risk, improvement in long-term reliability. Fairly level future rate increase.

Maintaining the current level of investments will provide the planning and necessary funds for equipment is replace/upgrade as required to ensure reliability of power supply

Reduces risk, reduces the number of assets beyond expected life, cost increase is high, moving to Scenario D does not reduce the risks that much more based to cost. Selecting Scenario A or B will put our distribution system at to high a risk.

Decrease on reliability risk while levelling future rate increases.

The current level of reliability is acceptable therefore maintaining the status quo would seem appropriate.

The current situation is in part the result of a deliberate reduction in re-investment in the mid 1990's to mid 2000's which has resulted in equipment beyond service life. If reliability levels are to be maintained or improved, then a balanced and consistent approach is required.

Comments (5):

Point 11 – "Scenario C" preferred by those are focused on reducing reliability risk and improving the long-term health of the system

Please use this space to tell us why you chose the point you did.
[asked of all respondents, n=103]

Point 11 – "Scenario C" (Cont'd)

This scenario keeps the transmission system at about the same health level as it is today and while the transmission rate increase is moderate, the overall bill impact is small and likely tolerable by most customers.

To maintain a consistent cost (although increased) with a higher reliability.

There is a lot of old components that need replacing already. reducing spent $'s will not enhance current performance.

Point 12

The system already has a health percentage of aged equipment and with the increasing reliance on the transmission system to achieve the government's environmental goals, reliability will only become more important.

Point 13

Ideally, the rate increase would be inflation plus some nominal percentage. However, if 3.3% results in a material decrease in service capability, this new information suggests that the next highest level of investment is appropriate, thereby putting this somewhere in between Scenarios C and D.

Point 15

Best choice overall from reliability and long term cost perspective

INNOVATIVE RESEARCH GROUP

Questions for LDCs

hydro one

Questions for LDCs: Summary

Local Distribution Company (LDC) customers (n=28) were asked a series of supplementary questions in order to provide them an opportunity to respond with consideration to the needs of their customers.

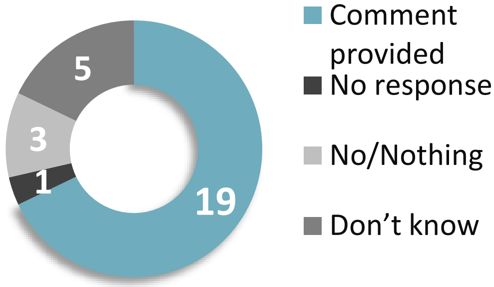
In response to an open-ended question, LDC survey participants identified costs and local support as the primary areas where they feel Hydro One can do more to help them meet the needs of their customers.

One LDC respondent, whose company provides electricity to First Nations and/or Métis communities, expressed their opinion that northern communities deserve more attention as the single-circuit connections result in vulnerabilities regarding power supply and interruption.

Eleven of the 28 LDC survey participants reported that their responses to Hydro One's transmission customer engagement survey were informed by their own customer engagement activities or other customer research.

Questions for LDCs:
Reduced costs and local support are where LDCs would like improvement

Q Is there anything in particular you feel Hydro One can do better to help you meet your customers' needs?
[asked of all LDC respondents, n=28]



It would be helpful if Hydro One were able to provide more reasonable cost estimates for their work. In past years, Hydro One was known for high costs of work and had an active program to reduce their costs of doing business. That effort seems to have waned now and costs have gone back to levels that many customers feel are too high.

Improve reliability in smaller rural communities, reduce engineering costs for distributed generation projects. Reduce operating, maintenance and administrative costs as a whole and pass the savings onto the customer base.

Consider both the financial and reliability impact of your actions on our customers.

Increased pre-planning for joint investments with the LDCs. Improve project management to achieve project milestones on time. Better transparency of costs associated to projects requested by the LDC for Hydro One to complete.

Communication and coordination of TS work requires significant improvement.

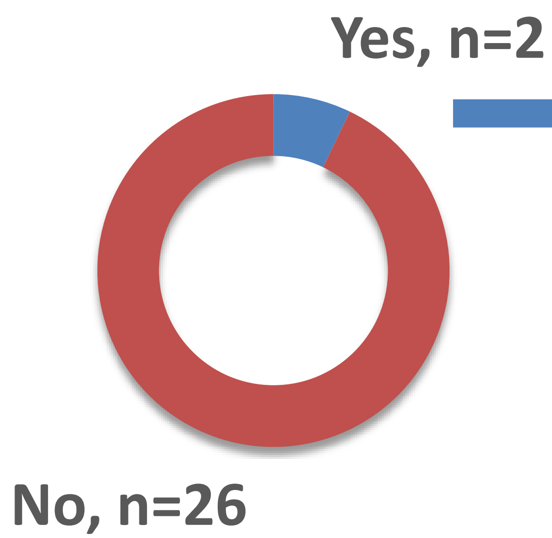
Better planning of maintenance outage notifications. Costs need to stabilize while at the same time allow for development of new loads in rural areas at costs that are reasonable and not prohibitive. Don't try and push normal maintenance and replacement costs onto new customers.

INNOVATIVE RESEARCH GROUP

Questions for LDCs (2):

About a third report that their responses were informed by prior research

Q Does your company provide electricity to First Nations and/or Métis communities?
[asked of all LDC respondents, n=28]



Q Is there anything in particular you feel Hydro One can do to better serve the specific needs of First Nations and/or Métis communities?
[asked of all LDC respondents who serve First Nations and/or Metis communities, n=2]

No.

The northern single circuit communities deserve more attention as they are more vulnerable in terms of supply and outage response.

Q Were your responses to this survey informed by your own customer engagement activities for the purposes of a rate application, or by any other customer research?
[asked of all respondents, n=28]

How Did We Do?

How Did We Do?: Summary

The rate of participation and the fact that all who started the survey went on to complete it suggest that transmission customers are eager for an opportunity to provide Hydro One with their input on future business planning.

Most survey participants (n=81) had either a “very positive” or “somewhat positive” overall impression of Hydro One’s transmission customer engagement. Only three reported a negative impression.

In terms of volume of information, most (n=78) felt that Hydro One provided “just the right amount” of information for the engagement.

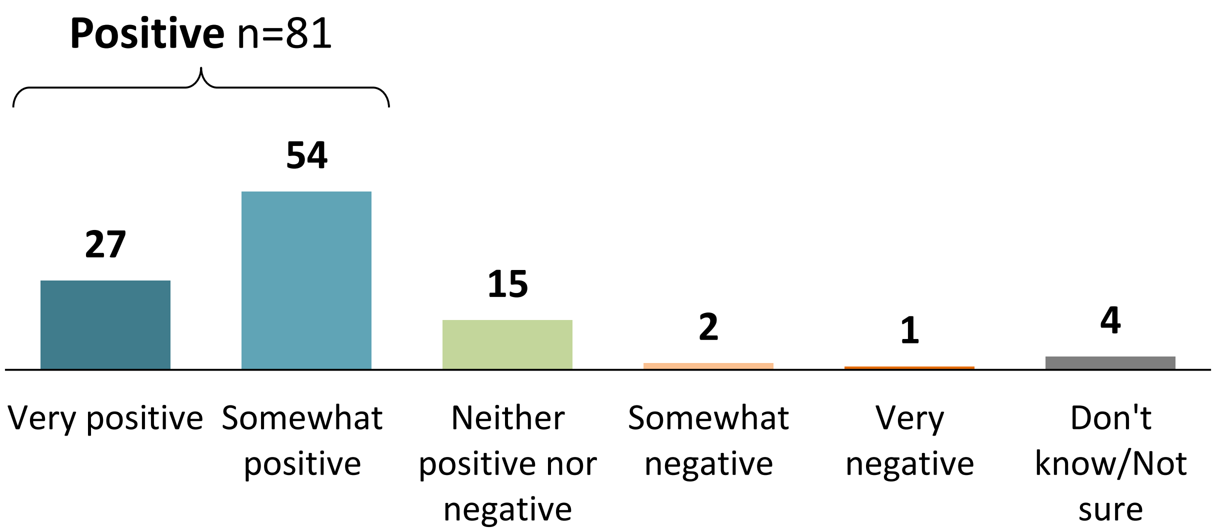
Further, only a handful felt there was any content missing that they would like to have seen included. Mentions included cost of service/efficiency planning, breakdown of necessary investments, and benchmarking information. Two participants referred to “dishonest/skewed conclusions”.

Asked if there is anything they would still like answered, a handful of participants would like details on Hydro One’s plans to improve reliability, to drive cost savings, and to improve customer service.

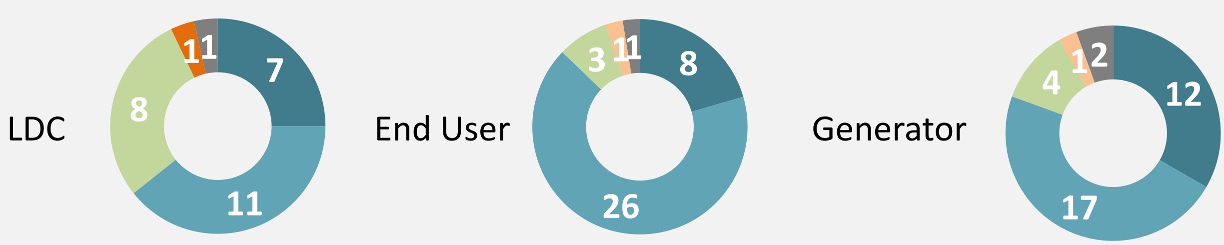
While few offered an opinion on how they would prefer to participate in future customer engagements, most of those who did comment said they would prefer the current format. A few mentioned in-person interviews.

Overall Impression:
Most rated the Transmission Customer Engagement positively

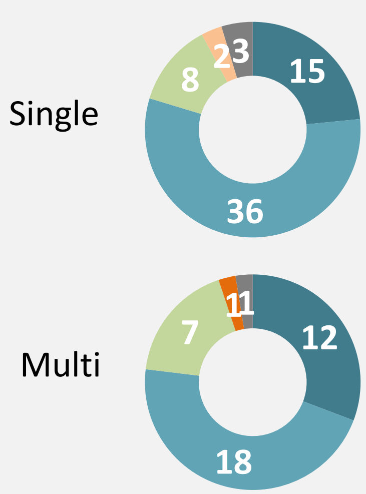
Q What was your overall impression of the Transmission Customer Engagement?
[asked of all respondents, n=103]



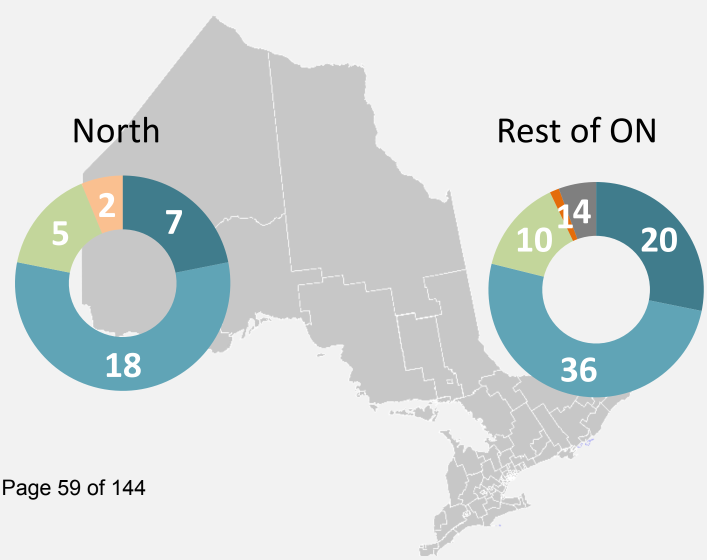
Business Segment



Single vs. Multi Circuit



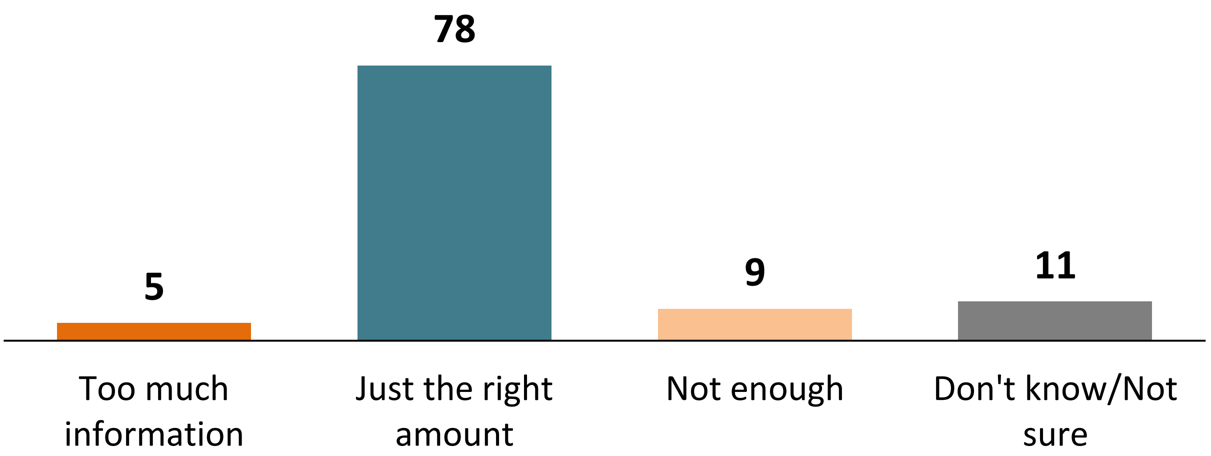
Region

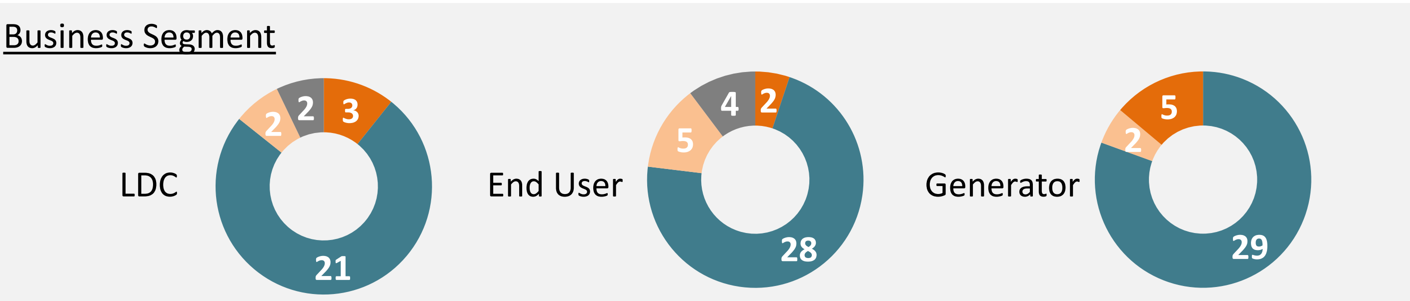


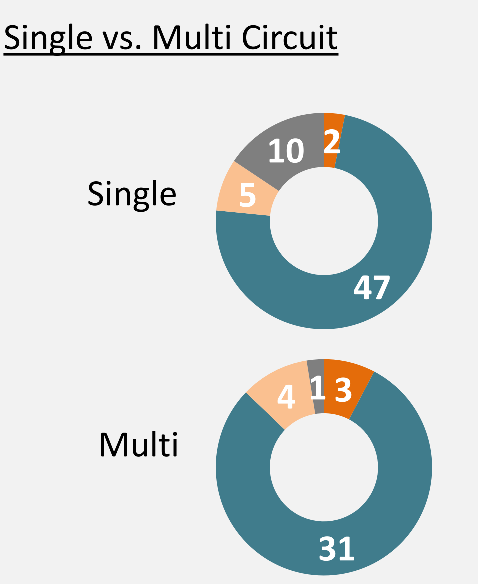
Volume of Information:

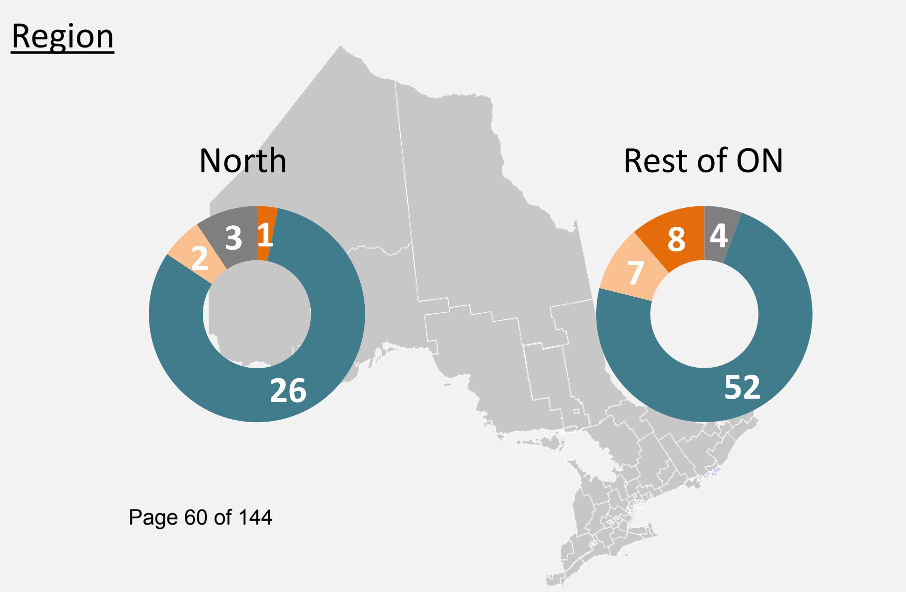
Most felt that "just the right amount" of information was provided

Q Did Hydro One provide too much information, not enough, or just the right amount?
[asked of all respondents, n=103]



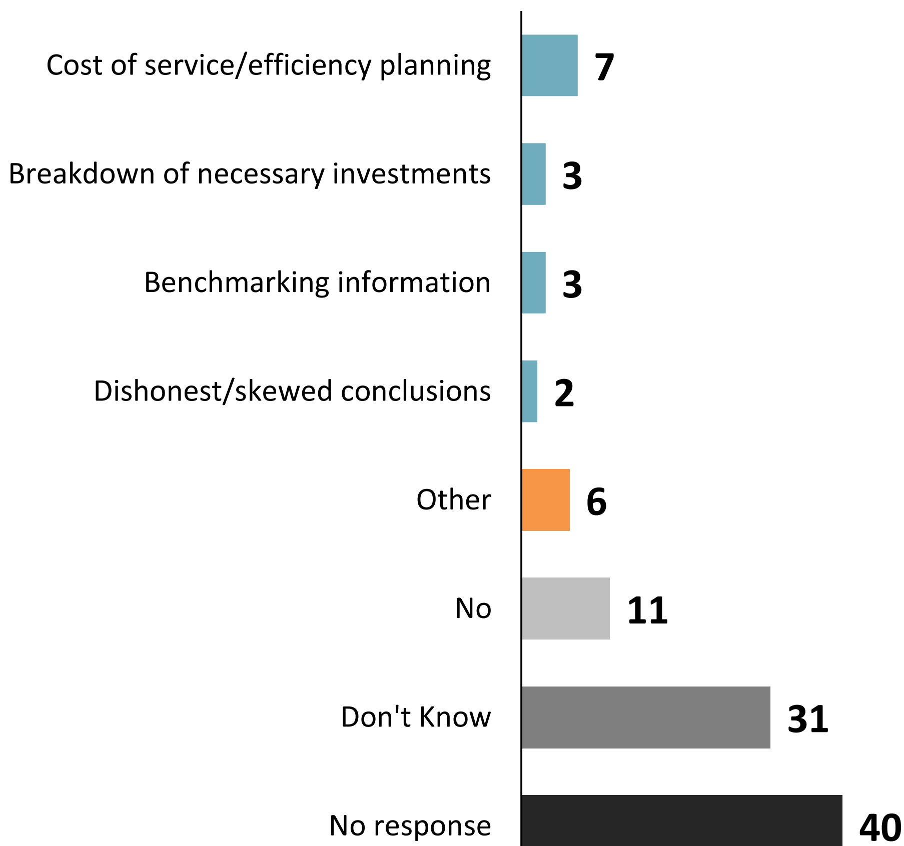






Content Covered:
Very few comments; top comments related to cost of service

Q Was there any content missing that you would have liked to have seen included?
[asked of all respondents, n=103]



Outstanding Questions:
A few comments on reliability, cost savings, and communication

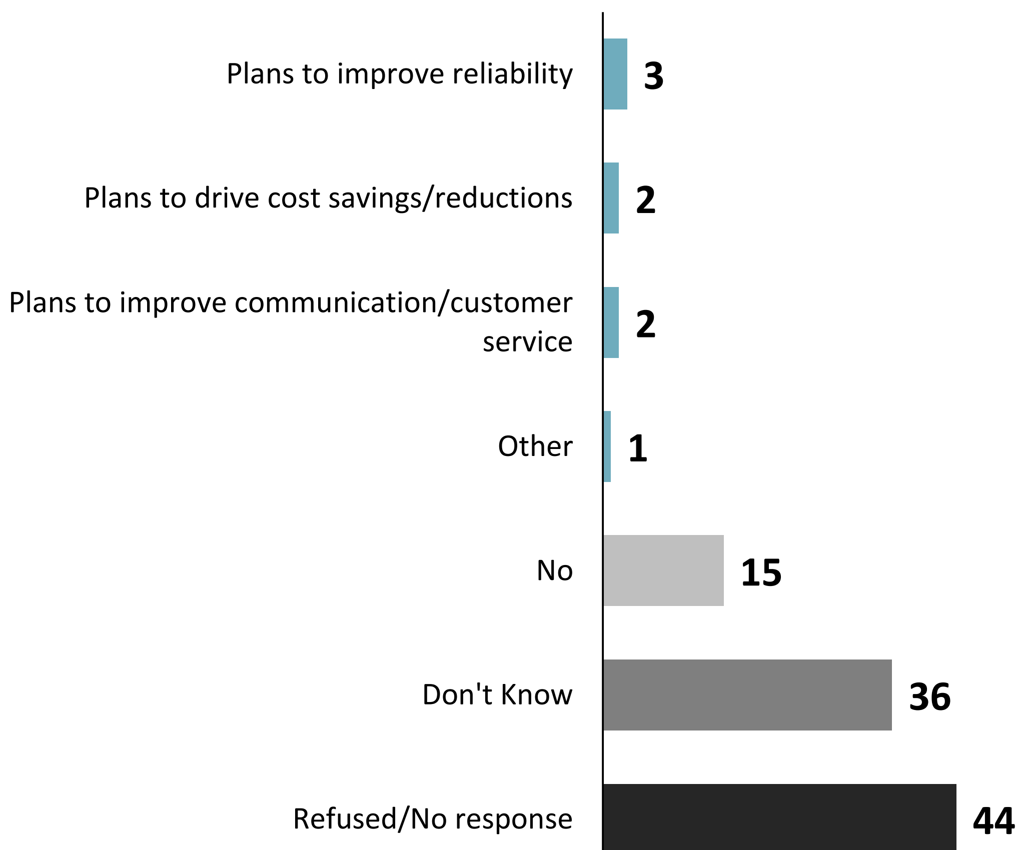
Q Is there anything that you would still like answered?
[asked of all respondents, n=103]

I would like to be able to review and understand the Hydro outage summary. Why is it so cryptic, it should be very transparent and not require an interpreter.

Please ensure to pass on the current level and expectations of customer focus to new employees of HONI; communications is key and appreciation of the cost to customers when the grid is not available.

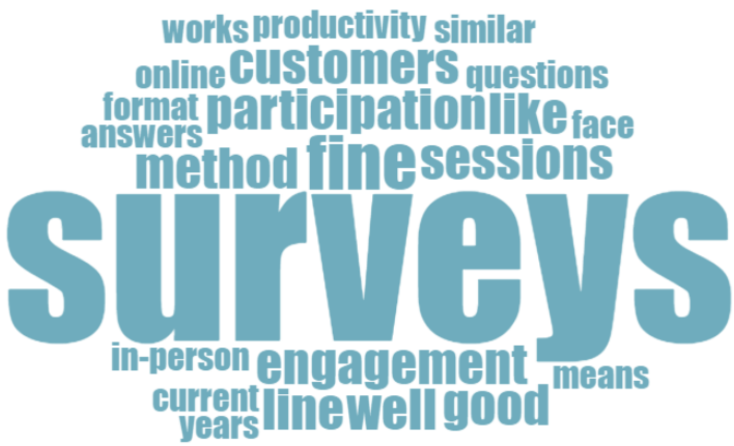
When are you releasing the plans? Will there be any dialogue on rates and where will we get a chance to review those comments?

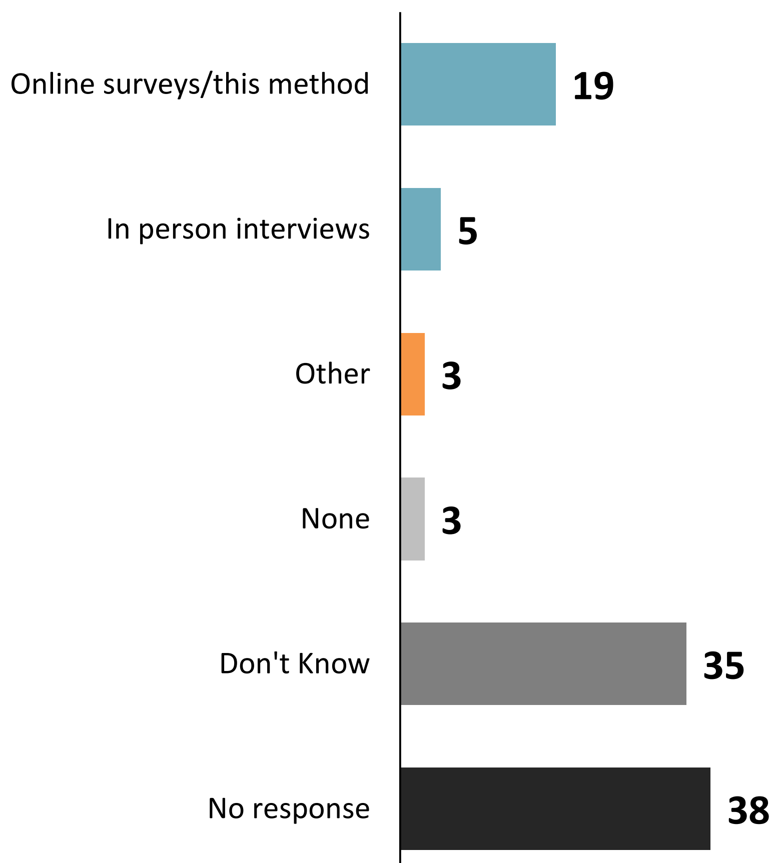
Innovation and lean management of Hydro One to drive cost savings and improve performance.



Future Customer Engagements:
Those who commented tended to prefer the current format

Q How would you prefer to participate in these engagements?
[asked of all respondents, n=103]





Building Understanding.

Personalized research to connect you and your audiences.

Appendix 1.1
Full Verbatim Responses

Suggested Improvements (1)

Q Is there anything in particular you feel Hydro One can do better?
[asked of all respondents, n=103]

LDCs

- Better Customer communication to LDC's
- communication re longer term plans
- Earlier engagement with impacted LDC's for station asset renewal projects.
- Timely contact with Account Rep to review transmission system reliability and incidents affecting [company]
- Nothing
- No.
- As an LDC, we deal with both staff from Hydro One's distribution and transmission business. We're somewhat satisfied with transmission system; but very dissatisfied with the distribution system.1) Hydro One needs to clean up the management of it's distribution system2) Maintain the existing service/performance of the transmission system3) Simplify ""event notification"": we struggle in decoding the location of circuits that are faulting.4) Demonstrate that they care about their LDC customers -- i.e. why won't Mayo come talk to the EDA? We'd listen and welcome the opportunity to work together.5) Improve their brand. When Hydro One ""screws-up"" the entire industry shares the burden of their poor customer relations. End customers blame our LDC for poor customer relationships that Hydro One has developed over the years. This makes running our LDC more difficult.
- I personally have no issues with Hydro One as the account rep and supervisors that I deal with always deal with our issues in a timely matter
- animal contact outage causes in stations - should be preventable - more can be done information sharing with outage causes and outage post mortem analysis
- More assistance with power quality investigations, especially where HONI customers are affecting our customers (i.e. HONI arc furnace customers causing voltage flicker issues for our customers)
- Upgrade facilities to allow for simple transfer to alternate circuit in the event of work required on our curcuit.
- Communication around job planning that affects our utility has been poor.
- our response is transmission based only and does not include distribution supplied locations. Better notification and planning with regards to maintenance activities would allow us to better plan and respond to our down stream customers.
- In the past year there have been a couple incidents where station supply was lost due to human error during station work. While only a couple incidents there is concern that perhaps the loss of experienced staff through retirement is manifesting as incidents.
- I would like to see the long term plan for Hydro One transmission investments to see how it fits with our business requirements. I feel Transmission Station investments should be pooled to avoid duplication
- Reduce cost of Engineering estimates. Improve reliability to rural areas. Improve communications regarding Distributed Generation projects with Local Distribution Companies. Improve power quality from transformer stations
- Work with the LDC utililities. Hydro One and the utilities are utlimately serving the same end use customer. As power system technology, communciatons, and IT technology advance at a rapid pace Hydro One must be able to be more flexible to enable Smart Grid and not to impede it. For example digital fault data is inherently available in new relays and systems. Make it simple and very low cost for LDC's to access this data. Cost transparency and no barriers. Work together toward solutions.
- Overall satisfied, however, some H1 assets are getting aged and maintenance times to return transformers back to service appear to be getting longer. Potential for future issues.
- Work closer with customers on planned outages. Resolve Middleport issue.
- there have been some concerns expressed over voltage regulation and insulators failures at the ts.
- Power Quality assessment could be streamlined. - Transmission expansion information/assessment could be done more quickly"

Suggested Improvements (2)

Q Is there anything in particular you feel Hydro One can do better?
[asked of all respondents, n=103]

End Users

- Share long term plan and how it affects my site
- Decrease the number of outages
- As a smaller industrial customer, we'd want more help / education in navigating the electricity system - particularly information and guidance on money saving programs that we're eligible to participate in (e.g. ICI)
- More direct communication with Customer
- Streamlining the process for connecting new customers would be beneficial, i.e. using one point of contact for all matters (including dealing with other agencies such as the IESO). It's a complicated process and time consuming.
- Satisfied with overall reliability but the costs make most of our business ventures uncompetitive and the lack of transparency and fixed nature of the billing makes it virtually impossible for us to effect the outcome.
- Timeliness of transmission station upgrades and renewal.
- Line Maintenance needs improvement due to two recent Sky wire failures.
- Continue to maintain the distribution equipment.
- Lower Costs
- be more reliable
- Response time to outages in [town] that require a crew to be dispatched from London is too long.
- Voltage adjustments to the 115kv supply (for province-wide power/demand response) can often have significant implications to our operation.
- Address "power quality"
- Better anlaysis/control of potential impact customers changes to their power systems have on the grid.
- Understanding the true meaning of reliability and the impacts this has not only on HO customers but the impacts this has on its neighbours.
- We would have selected Satisfied if it was provided. Overall, our service and interaction with Hydro One is very good. However, the bureaucratic processes are very slow.
- Keep the power on and clean (power quality, not sourcing), and don't charge us a fortune - I'm getting a 73 Chevy and paying for a 2017 Porsche Cayenne
- Add capacitance on S2B line?
- No we are happy with your service
- Take on a customer centric approach. Recognize that large industrials are important customers. Provide proactive resolution to problems Be more flexible and less driven by an internal set of rules that make very little sense to others.
- Identify, plan and execute any mitigating factors that would improve power reliability to the mill site and [region]

Suggested Improvements (3)

Q Is there anything in particular you feel Hydro One can do better?
[asked of all respondents, n=103]

Generators

- Communication of outages
- early notification for outages (when & duration), understand this can be difficult but the more lead time the better
- Consider more flexibility in internal rules so interests of both Hydro One and their customer are addressed.
- Improve forecasting / Cost estimating capability when partnering with generators.
- The cover process is somewhat ambiguous and the cost and schedules are not particularly accurate
- Customer communication
- Better coordination of outages and associated changes to same which might affect generating stations on the same network.
- Follow up on new employees in OGCC control room
- Improve Hydro One's procurement process to minimize delays in resolving equipment issues.
- Outage planning. sometime last year, there were in total of 4 planned outages were scheduled at different time slots on the same day. which it was quite confusing. later on I contacted the Hydro One officer and go clarification.
- Plan HO outages during our low production times to limit the loss of revenue to our business
- taking into consideration the customers assets and the difficulty seasonal outages can be on the operation.
- Planning & grid control needs to get better at communicating customers. Most likely turnover or retirement has resulted in new personnel with not necessary the same level of customer service.
- "All Hydro One's responses are governed by rules No special cases taken into account Cost of any interface too high"
- Service the Seaforth T/S so we have less outages
- Coordinate planned maintenance outages - proper lengthy notice
- "Interaction between technical/engineering groups and customers early in the connection process needs to improve. Improved sense of accountability required at Hydro One. Actual connection costs coming in well outside acceptable industry variance ranges. Paying significant amounts for connection estimates that provide little value (+/-50% estimate is unacceptable from any engineering firm).No sense of urgency, unless the lights are out."
- Greater communication on outages, It is very difficult to understand what all is required or not required for outages.
- Clearer direction on how potential upcoming outages affect the customers and for how long.
- Outages - unknowns and changes have been issues...last minute they just asked us for an outage to connect another windfarm with <30days notice on a project in the works for the past 3 yrs. Rates for remote power supply are incredible...bringing the total cost to nearly $0.25/kwh for our stations service for our switch station!
- Estimation, planning and engineering could be more proactive with generators. A lot of delay in getting cost estimate and work planning are having huge impact on our business.
- The distribution line running between [location] and [location] seems to have a number of extended outages which does cause us some headaches.
- respond faster to inquiries
- Plan outages better and work in better with clients to minimize impact on their business
- Ensure reliability of supply by ensuring equipment supporting our plants is maintained to highest standard. Ensure management and training of staff supports safe and error free operation of equipment supporting our plants particularly the nuclear fleet.

Performance Metrics (1)

Q How do you know if Hydro One is doing a good job for your business?
[asked of all respondents, n=103]

LDCs

- provides reliable supply and responsive service
- The transmission planning will dovetail into the distribution planning process to drive overall system efficiency.
- Timeliness of response to inquiries. Delivery point reliability improvement year over year.
- We haven't had a total loss of power in the last few years due to material degradation or anything such like that
- Timely responses from inquiries Outage frequency and duration is minimized Generally helpful and courteous staff
- Availability of Executive staff to discuss matters, field staff willingness to assist when needed, open minded, willingness to resolve issues
- good communication and timely responses
- Reliable service.
- Loss of supply statistics
- Win back end-customer confidence and improve its brand.
- same as above the people that I deal with always either answer the phone right away or call me back as soon as they can
- Several points to consider - level of engagement on issues - staying current and open communication, level of effort along prevention - are you really doing the simple things, are you easy to do business with, can you actually get things done when you say your going to do it.
- We can gage the performance of the HONI system via the number of outages due to loss of supply
- Keeping the supply of power on
- Few outages, either planned or unplanned
- Reliability and costs are the primary drivers in the measurement of performance.
- We look at overall reliability as well as Hydro One's understanding and explanations of the incidents that have occurred.
- We measure reliability based on Loss of Supply. Quality and timeliness of responses from Distributed Generation and Engineering groups.
- Reliability, costs, general customer service, responsiveness, operations service and interfaces, ease of doing business with, relationships. Enable the LDC to forward their objectives.
- Reliability to date has been good, however, increasing frequency/duration of reduced redundancy due to extended maintenance periods. Resulting in higher potential risk exposure for customers.
- No interruptions in supply and no voltage issues.
- Reliability of supply.
- - based on reliability (is excellent)- responsiveness to queries

Performance Metrics (2)

Q How do you know if Hydro One is doing a good job for your business?
[asked of all respondents, n=103]

End Users

- Unplanned outages are minimal, good communication on maintenance being completed
- They are very communicative
- Power Supply reliability
- Forced outages are reduced and power quality is improved.
- Reliability is important but at a cost that makes us uncompetitive and sends jobs abroad is not sustainable and will hurt all citizens of Ontario
- When100% availability is achieved
- Great customer service by providing assistance after failure of [company] Power Transformer T5.Greatly improved communication of shutdown work, long term planning needs etc.
- Reliable electrical power supply.
- Costs to businesses are kept in control. Evidence that cost control at Hydro One is in place and effective.
- Power service is reliable and I seldom receive any calls/complaints from our operations groups. Also, our account manager, Jim Perpick does a great job of keeping us informed and following up on any issues we raise with him.
- if I do not have to call them
- We are provided with the reliability information from our Network Management Officer.
- responsiveness to reporting requests, capital projects and market data. Very pleased.
- Electrical outages are rare and when there is an outage they are quick to respond and communicate the outage
- Number of outages my business experiences or individual equipment trips due to voltage sag
- Number of power interruptions that occur.
- Open dialogue and regular face to face visits reassure us HO understands the impacts of safe reliable operations
- 1) No unplanned outages and consistent power quality. Score 8 out of 10.2) Supportive in planning and outage response. Score 9 out of 10.
- The power stays on, your sags, swells, harmonics etc do not destroy my instrumentation, and the cost of distribution is strongly competitive with what is charged by other jurisdictions in North America in which are situated my competitors who are trying to put me out of business
- Willing to meet with us to discuss our problems. Do everything possible to keep us supplied with power. Upgrading the S2B line in the past few years.
- We seldom loose production because of hydro outages
- My power is still on
- Probably if there was very little noise about Hydro, we'd know that Hydro was doing a good job.
- Interruptions are at an absolute minimum and wherever possible with as much advance notice as possible.
- Power reliability and quality issues reduce to once per year.
- reliable supply of electricity at a reasonable cost
- Our electrical department informs us of any issues with Hydro One and how things were handled to resolve
- Good communication, fast response. Good job guys!

Performance Metrics (3)

Q How do you know if Hydro One is doing a good job for your business?
[asked of all respondents, n=103]

Generators

- No surprises
- in simple terms as long as the electricity runs through the lines and there are no disturbances causing issues or damage to our equipment then everything is good
- Regular communication at all level between hydro one steakholders for ongoing projects and maintenance activities on customer site.
- Sustained, reliable electricity delivered to our door. Our joint work - when the actuals are more in line with the plan, be it outages or length of outages, and cost.
- Reliability, responsiveness
- This survey is a small step forward in Hydro One determining the needs of its customers.
- When I don't hear about any business interruptions or scheduling conflicts.
- I think yes. Never had problems so far.
- They work with us in outage management
- Performance is based on Hydro One's ability to provide its service reliably and implications to our operations.
- stable grid system, less impact on the customer side are all we need.
- If the lines remain open for business and interuptions are held to a minimum
- Timely and accurate billing and reconciliation. Reliable power.
- Effectively communicating and ensuring to work with customers to minimize impact of business interruption
- that the delivery of Hydro is reliable
- Fewer outages
- Some communication on outages
- By the way that Hydro One coordinates planned equipment outages with the customer needs.
- No metrics that Hydro One is willing to provide. cant even get a detailed itemized statement for a connection to see how they performed against their estimates.
- no issues with unplanned outages, invoices are accurate
- On rates, no idea...on work around transmission doing fine, meeting with us generators every 6 months to try and best facilitate outages/repairs/upgrades
- We are working with HONI for generator connection since 2008. At that time, HONI were more proactive working with generator. Since 2-3 years it seems like there is no willing in resolving issues.
- If they are doing good then we won't have any surprise outages and/or time we can't inject into the grid.
- The reliability of the M2W transmission line is very good which is essential for our business.
- results
- Communication concerning outages; timely and accurate responses to queries; price
- We work collaboratively with Hydro one and participate in numerous committees overseeing areas of mutual concern

Suggested Additional Outcomes

Q Are there any outcomes we missed?
[asked of all respondents, n=103]

LDCs

- Timely delivery of project milestones.
- no
- Communication - transparency and timliness
- Price or cost- what is the value for money
- Costing allocations should either be socialized on the whole rate base or significant lead time to
- Easy to deal with.
- System capacity - Have a transmission system with the capacity to meet the needs of our customers.
- affordability - lower rates

End Users

- Weather risk mitigation - system hardening
- Flexibility of planned outages schedule to accommodate Customer restrictions
- Costs ; You will say its inferred in productivity and others. This is the reason we are in a mess.
- Inclusion of major customers like Dofasco in communication of future local investments
- Reduction on cost of GA
- So far none
- The slider above does not work in my browsers.
- New connections and upgrades built and energized on a timely basis.
- Responsiveness and personal assignment of a customer service representative for major customers
- Outage co-ordination with plant outages minimizing single line exposure.
- Your wages reflect those in industry, so that we don't keep losing our best people to you
- something about 'managing and accommodating growth and expansion with IESO through SIAs / CIAs'
- Response from local Hydro One team to respond to emergencies related to un-expected site power outage

Generators

- Predictable schedule preparation and execution
- no
- Grid Capacity Expansion
- COST COST
- Communication within IESO and HONI
- Efficiency of operations - reducing the bureaucracy, having decisions at lowest reasonable level
- general communication about direction of HONI certainly helps me as a customer understand ramification
- Streamline the customer service experience to be able to reach appreciate parties efficiently.
- Technology/Standard requirement
- Respect for other people's property - eg talking with property owners before accessing

Comments on Customer Outcomes (1)

Q Do you have any specific comments or suggestions regarding any of the seven outcomes that you just rated or any additional outcomes you added?
[asked of all respondents, n=103]

LDCs

- ensure that there is regular communications and dialogue
- None
- More timely response for communications and delivery of project milestones. Safety has been a concern when Hydro One crews have been working on shared ownership sites without engineered drawings under regulation O.22/04.
- Hydro One needs to fix its business processes and find productivity. I don't believe senior management in Toronto has the tools or workflow processes to manage or monitor projects efficiently in Northern Ontario. Until they sort out their internal workings, they don't deserve any rate increases.
- no
- You can do more with less on all of this - its not a trade off between money and results - we need the results described and we need it at a more affordable rate.
- Only proceeding on productivity projects that will guarantee a financial payback and reduce rates for all customers. Tried to provide feed back in suggested outcome 1 box but was limited to one line of text. Frequency of outages is a higher priority than duration when dealing with the general public
- Cost estimates for work to be performed by Hydro One are extremely high. While part of the issue is the class C estimate contingency, those costs cause a lot of concern for customers considering connections for generators.
- Cost reductions should be a top priority and given serious consideration and not just lip service.

Comments on Customer Outcomes (2)

Q Do you have any specific comments or suggestions regarding any of the seven outcomes that you just rated or any additional outcomes you added?
[asked of all respondents, n=103]

End Users

- Safety and Environmental Stewardship are "table stakes". If they can't delivery these 2 outcomes, they have no business operating a transmission system.
- The main outcome should be to provide reliable power at the best possible cost which should be benchmarked to a world standard to remain competitive and to make it so people don't have to choose between eating and having access to power.
- The "extremely important" responses for my organization are related to our activities which are primarily linked to [removed for privacy]. Were we primarily an office accommodation portfolio, the responses would have been less important.
- We have observed improvements in overall customer service.
- Productivity should be a key focus at Hydro One. There is little evidence that this is a consideration at any level in the organization
- Power Quality is an integral part of Reliability.
- Some of these question miss the mark 1.I don't care about productivity; I care about costs going down; 2. If power didn't keep going off, then I would not care about customer service 3. Safety and environment and politically correct questions - don't kill anyone and don't poison the planet; otherwise, get on with the job (do not use these answers as a license for expanding PC topic bureaucracy) 4. Once we are out, restart takes hours anyways; we are more concerned with not going out, then with outage length - based on past performance, we have had to install all kinds of back up generation already (costs are sunk - back to the 73 Chevy)
- Customer service should be accomplished through culture and not cost the rate payer anything. in fact, would mean savings to the rate payer. the rate payer has paid significantly for reduced emissions. outage restoration - we are on the longest radial line at [location] and incur 25 outages / year. this is unacceptable and costs us an estimated $6 M/year.
- All outcomes are equally important. It is hard to have one and not the other. Ultimately we do not see the environmental stewardship piece directly at the mill site.
- We have a good relationship with Hydro One

Comments on Customer Outcomes (3)

Q Do you have any specific comments or suggestions regarding any of the seven outcomes that you just rated or any additional outcomes you added?
[asked of all respondents, n=103]

Generators

- basically each and every item is extremely important, some of these are important to us as end users or generators and others are important to Hydro One as the service provider. Not sure if the questions wanted us to rank them which I thought would be more informative
- no
- Grid Capacity Expansion
- As a generator it also extremely important that HONI is available to take the power and transmit it reliably.
- Customer service & reliability is very important and your area or customer representatives have done an excellent job conveying this message to us.
- YOU MISSED COST OF EVERY ACTIVITY UNDERTAKEN BY HYDRO ONE
- No
- i like when you mention safety, the industry is very high risk and nice to see HONI as a leader
- There are still some old requirement that would need to be updated to reflect the new reallity, mainly in communication media for teleprotection.

Comments on Ranking Customer Outcomes

Q Comments:
[asked of all respondents, n=103]

LDCs

- Safety and Environmental stewardship are not my interests but your employees and the governments interests respectively - as a customer I need performance improvement in all other areas and results now and need to know and trust that you have it and are going to do something on it.
- Customer Service is affected by not only the customer service through communications and follow up but it is driven by the quality and reliability of the service of supplying electricity.
- As a customer, reliability and outage restoration are important outcomes. I should be able to rank those at the top without sacrificing Safety or the Environment. This survey does not give that choice.
- Number one for my customers is rates. Productivity is not a direct reflection of that, but is similar.

End Users

- Safety and Environmental Stewardship are "table stakes". We don't consider them outcomes that should be ranked, but rather core deliverables of a transmission company.
- The focus on environmental steward ship and the solar and wind ventures it generated where ill conceived and poorly planned and have costs significant hardship on the citizens of Ontario . Although important it was very badly managed .
- n/a
- Reduant question although most important is reliablity and productivity
- This is difficult as they are all important.
- This ranking is predicated on Hydro 1 executing these priorities - if power quality and reliability are not improved, then customer service becomes much more important.
- Note that although power quality is no the bottom it is also extremely important

Generators

[NO COMMENTS]

Pace of Investment (1)

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

LDCs

- produces more certainty in planning and rate increases
- Spreading out investments allows you to prioritize as needed at a sustainable run rate, in addition to evening out the rate impact as much as possible.
- over half a century old, it's easier on the elderly population which is increasing to financially handle any smaller increases because of fixed income
- As a customer ourselves managing the rate increases so infrastructure investments are financed at a reasonable pace ie. inflation plus 2%
- It is unlikely that rates would ever decrease. Good practice would be to manage assets without too much of an impact on the customer and rates.
- Hydro One needs to get their internal house in order before it inefficiency spends any more ratepayer dollars.
- Why cant you do more with less? Why are you trading off performance for costs - are you doing and getting the most out of the resources you have? I vote that one.
- It is a reasonable approach between responding to excessive failures (by deferring investments) vs the additional cost (spreading the investment).
- Local needs must be considered and vary
- A spread of investments avoids putting costs to ratepayers in the future and avoids the risk that future ratepayers may be in a worse position to pay the increased rates. It also avoids the cost of frontloading the costs when there is currently much customer concern over their ability to pay. This middle alternative seems to provide a reasonable cost balance while somewhat increasing reliability risk.
- I believe that Hydro One can find internal efficiencies to help offset rates while continuing to improve reliability.
- We cannot defer our costs to make the next generation can pay.
- Locally many assets are getting aged and reliability is already at risk. Higher capital investment now along with a push for higher productivity and lower internal cost would be the preferred approach to reduce rate impacts.
- Over the long-term this provides the best return on investment
- This is the philosophy we have taken as a distributor. At some point affordability needs to be considered in capital expenditure levels year over year.
- Stable investments assuming reliability and PQ are held constant.

Q What does it depend on?
[asked of those who answered “it depends” to previous question]

- A management plan that gets the most out of the team it has - I dont believe you have that yet.
- it would have been useful if you could have quantified the magnitude of rate increases and not just higher or lower. Are you talking about 1 verses 2 % or are you talking about 1 verses 10% It is hard to make a good decision until the impact is known

Pace of Investment (3)

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

Generators

- Current state of equipment
- I believe it's the best thing for the ratepayer. No shocks. I understand why Hydro One may see it differently, but the goal is to provide power with as much consistency in price as we can. Quick raises in price is not looked upon favourably.
- infrastructure drives reliability
- it's pragmatic
- Ontario residents are already suffering high energy costs.
- Decrease in system reliability or increases in equipment failures negatively impacts our facilities operations and earnings.
- Price only will go up if waiting.
- I dont believe delaying the investment would be prudent and we would feel that in the future with reliability and outage issues. I dont see our business expanding too much in the near future so i would prefer to spread it out evenly,
- less impact on cashflow for companies
- CUT COSTS NOW e.g salaries by 15% to 30% for sunshine employees
- It's real
- Because I believe that internal productivity increases within Hydro One should be the first priority
- Plan the requirements, allow for the unexpected (which will be minimal if planned properly). Capital programs are inherently lumpy!
- i say this but a change is an election away. We need the long term vision and goal the strive for.
- To increase capacity in the short term to be able to add more renwable energy to replace fossil and nuclear generation.
- Easier to forecast for business plan with stable rate increases;
- manageable to ratepayers while insuring reliability
- It isn't as simple as a broad answer above. Some items are more critical and should be completed upfront. Other assets should be sweated and delayed. New technologies and options should be considered for some investments

Q What does it depend on?
[asked of those who answered “it depends” to previous question]

- Customer connection requirements and timing of those. Show some flexibility! just because a new customer connection falls a year outside the Hydro one plan should not necessarily require the customer to pay the full advancement cost.
- I think you need to do some investments, spread payments over time, but revisit and optimize costs...ALWAYS be more productive, look for economies of scale, look to streamline and cut where people or assets are not productive and a drag on the system, literally and figuratively...have yet to see HONI do this
- Safety, reliability, growth regions, new technology, innovation - it shouldn't just be an all or nothing approach.

Pace of Investment (2)

Q Why do you prefer the scenario you chose over the other two scenarios?
[asked of all respondents, n=103]

End Users

- Most can not afford higher rates, and delaying will just cause future generations to deal with legacy issues
- 1) Predictability in pricing2) Not letting the system fail
- Good balance
- I don't agree it will mean higher increases in the future . AT least it may eliminate investments that are needed. We have made a lot of investments in the past we don't need. This will prevent that.
- This scenario depends on the specifics of investments, their value and benefits.
- Hydro is too expensive.
- Given that the current electricity rate in Ontario is among the highest in North America.
- ontario pay more for hydro then anybode around. How we can stay in business and compete
- Financial impact,
- Balanced investments so rate increases are aligned with inflation. Electricity in Ontario is extremely expensive and has put Ontario business at a significant disadvantage. While investments are necessary so are ensuring competitive costs.
- Prioritize, plan and execute.
- HO should look for internal savings/efficiencies before rate increases to fund not only growth but reliability and maintenance projects. This is how industry operates, we would expect the same from HO.
- Preference is to have stable rate increases for financial planning provided that reliability is not compromised.
- Folks - start doing root cause and figure out your problems - you have bought crap breakers and are now replacing them, crap ceramic insulators and are now replacing them, and crap transformers that have fried equipment vital to our operations (I'm assuming that these problems are not caused by poor maintenance done by your very lucratively paid employees). Let's figure out how much money you are wasting, and fix that first. What is your ROI on the vaunted IT system - are you there yet? You need an industry culture and an industry style focus - once we see that and its results, you will find that you don't need anywhere near the stuff you think you do - and this is assuming that you are not trying to pad the asset base to maximize regulatory returns to your new shareholders - big assumption.
- Invest now (in the north!), where there has been no investment in decades. we are at the end of long, inefficient lines at [location] and [location]. we were forced to invest in a transmission line in red lake b/c hydro was reluctant to do so.
- Its unfortunate the state of power in Ontario. Hydro One should reflect on their performance vs other provinces and states. What are we doing wrong when it costs so much to produce power vs other areas?
- Would prefer option on invest now, but the cost may be too high, so spreading costs may be better

Q What does it depend on?
[asked of those who answered "it depends" to previous question]

- Not knowing exactly what the investments are made to achieve/address and their impact/cost this question is difficult to answer in general.
- Rate increases vs internal savings. Demonstrating internal efficiencies and cost cutting (salaries) eases the impact of continuous rate increases.
- Getting what you really need right (nowhere close to that yet), getting your operating costs in line (lot's to do there), what your financing charges are compared to ours (we have to borrow to pay for you guys, and your rates are likely lower than ours), setting priorities that provide a level of priority for economic health of your jurisdiction vs convenience.

Reliability (1)

Q When you are talking about transmission reliability, what does that mean to your organization?
[asked of all respondents, n=103]

LDCs

- Our customers are nearly 100% depended on supply we receive from Hydro One. Therefore reliability has a direct impact on our customers.
- Reliability of service to our delivery points
- have the "clean" transmission supply continually available
- Transparent communication on system operations that create power quality or outage events in the distribution system.
- Sustained outage of transmission circuits resulting in loss of load at WNH delivery points. Recent experience is these events seem to happen more frequently on double circuit transmission lines when one line is already out for planned maintenance.
- We only have the one circuit in our community so the reliabiliyt of that circuit is quite important to our township. For example, winter months where we have lost power for 3 days in the middle of winter.
- Availability of power and or service
- A system that is not down due equipment breakdowns
- adequate and sufficient power. Power available when you need it in a safe manner
- Consistent supply of electricity and fast response to interruptions.
- Keeping the lights on
- Uninterrupted supply. Their Tx reliability is very good!
- this is extremely important as an LDC our customers count on us to deliver a safe a reliable system and we expect the same form our provider
- No loss of supply events greater than x for longer than y - x and y are terms I am certain will mean something different to most. It is also accepting a go forward view as to the level of managed risks we are being exposed to - we should not accept a level of risk of outage greater than Z when planning and operating the system
- Reliability is a measure of how often the system is available for use operating
- Reliability being the dependability of the service and being able to count on the reliability of power to be available without itneruptions. HIghly reliable versus unreliable.
- No outages
- It is presence of in specification voltage levels and adequate current availability.
- Reliability means minimization of incidents where power is interrupted for more than a couple seconds. It is closely related to power quality and is often used interchangeably by customers that are sensitive to power quality issues.
- Reliability is key in providing service to our end customers. Ensuring safe reliable electricity is imperative.
- duration and frequency of loss of supply incidents that affect our customer base.
- Essentially reliability it is the time the power is available. Being a dual element system the reliability is generally excellent. However, since a transmission outage can be a major event, the risk of an outage due to a forced or planned outage of one of the elements is also a consideration.
- For our organization, reliability would refer to the availability of at least one of the two supplies to the station supplying our feeders. For single source stations, the lines are maintained to provide alternate supply routes via switching. Our customers have growing expectations for availability of power and we in turn rely on the Hydro One transmission system to allow us to service our customers.
- Power available 24/7 at the correct voltages and with no curtailments of supply
- Frequency and duration of power interruptions.
- relaibility of supply - availability of power

Reliability (2)

Q When you are talking about transmission reliability, what does that mean to your organization?
[asked of all respondents, n=103]

End Users

- No unplanned extended outages
- no outages and constant electricity quality
- 1) No interruptions2) Having a ""plan B"" - redundancy built into the system
- Continuous, uninterrupted and good quality supply of power to Customer
- Reduction of unplanned outages
- 0% of unplanned downtime with respect to electrical supply. Power is a significant input to the operations, safety, and protection of the environment. Unplanned outages have high consequences.
- Continuation of services, minimizing lost time due to equip./line failures
- I translate it to availability. I don't expect 100 % it can be defined. No outages lasting longer than 8 hours except with one catastrophic outage once every 3 years lasting no longer that 3 days. 95 % of days with no interuptions. That is what I would expect.
- Un-interrupted power supply.
- No unplanned outages...
- Zero interruptions, very low number of unplanned events such as loss of redundancy and power quality incidents (particularly voltage sags).
- 100 % power availability and 100% quality
- Reliability = Uptime or ability to fuction
- No power interruption at all times. Our facility is 24x 7 service industry and continously power is a key to all the safe operation of the plant and to keep the production to meet the customer demand
- No power interuptions means higher productivity.
- Power available to run our pumps on a continuous, uninterrupted basis.
- A reliable transmission is delivering electrify to the distribution point in a form (within reasonable tolerance) that doesn't cause any disruption to our plant production process.
- Mean a lot. Any interruptions and loss of power cost us lot off money and potentially lose a customers
- We are a 24/365 [removed for privacy] operation that is energy intensive and trade exposed. Power outages have a large negative effect on the bottom line.
- Uninterrupted supply of electricity to meet the utilization of our operations.
- Consistency in product and service supply, with minimal interruptions or periods of reduced service quality.
- power outages cause major issues on campus, research experiments are compromised, failure of electronic equipment increases from outages or blips. There is a financial cost to each recovery from an outage, at times in the tens of thousands
- Number of times each year we experience a partial or total plant trip due to the transmission system.

[CONTINUED ON NEXT PAGE]

Reliability (3)

Q When you are talking about transmission reliability, what does that mean to your organization?
[asked of all respondents, n=103]

End Users

- Percent of the time sufficient power is available to operate our facility.
- Consistent power supply, little to no unplanned outages. Planned outages are also part of reliability, so we as the customer can plan as well.
- 115kv power available 365 days 24hrs a year
- zero interruptions which force an unplanned shutdown of our facility.
- No unplanned outages and consistent power quality. (Ie no impact to production).
- Power stays on in such a fashion that it does not kick out and/or burn out instrumentation, VFD's, and other (typically expensive and vital) equipment
- Steady operations, with long MTBF.
- Very few unplanned outages
- That the Light is on when I turn on the switch
- power available around the clock.
- Consistency of supply.
- A measurement of uptime
- Consistent supply of quality electricity with few if any unscheduled interruptions
- No unexpected outages or variance from agreed upon target voltage supplied to site
- Any power outage can cause a loss of production. And due to the limitation of travel can cause issues with men underground

Reliability (4)

Q When you are talking about transmission reliability, what does that mean to your organization?

[asked of all respondents, n=103]

Generators

- Providing stable and consistent energy as promised
- uptime while maintaining excellent power quality
- Minimal power interruptions.
- Power from the grid available when required and no generation interruptions
- Our ability to get power onto the grid. It's knowing of planned outages, reduction of forced outages, limiting time, length and number of outages. I think Hydro One does an excellent job of providing contingency.
- There when needed
- Maintaining the resources required to provide customers with the proper delivery of electricity.
- The ability to generate our production (electricity) and sell our product.
- Having no service interruption or fluctuation.
- The ability to generate and export power.
- Reliability means we can rely on the transmission system to be available at all times to allow our generation facilities to transmit electricity to the grid.
- Stable connection, less outage, long term operation.
- up time vs downtime
- Systems are available and trasmitting our electricity without interuption.
- As a generator it also extremely important that HONI is available to take the power and transmit it. When developing projects cooperation and schedule adherence is very important.
- Continuous supply of quality energy
- The grid is ready and available to deliver our electrons at all times, primarily during on-peak periods.
- Reliability to us is that we are able to transmit power into the H1 owned facility, as our core business is to sell power to the IESO
- Availability, minimize planed and forced outages
- Minimisation of production revenue losses
- Less down time on the grid with stable power. Very important
- No unplanned outages
- The number and duration of transmission line outages
- Proper technical operation, no unintended outages due to equipment malfunction or failure. Planning of outages taking into consideration customer impacts and full up front communications with those customers, not just a select few.
- power is flowing as required with little to no down time.
- uninterrupted power transmission
- Having a stable and reliable grid for which power can be injected as a generator.
- Ability for the grid to stay operating, including managing around foreseeable unforeseeable events for high "availability"
- It mean that the transmission system is always available.
- Electricity flows when needed and no power outages;
- Grid availability as we are a renewable energy generator and rely on the grid to sell our product.
- low outages due to equipment failure
- Reliability means the customer can understand when power will be on, and will be off - they can plan for this and understand that if Hydro One says the power will be on; it will be on. In the event of storms or other disruptions; Hydro One will move swiftly to return power from unexpected events.
- Grid reliability isssues do not impact generation from nuclear and other large generators, low risk of blackouts

Comments on Reliability

Q Is there anything else you would like to add on the topic of reliability?
[asked of all respondents, n=103]

LDCs

- Their Tx reliability is very good. Communications is more important to use the loss of supply (mind you, loss of supply rarely occurs).
- Power quality is most important to large, power quality sensitive customers while small commercial or residential customers are most concerned with the number and duration of day-to-day interruptions. Most customers have the most tolerance for outages due to major events as they can understand the reason behind the outage while the cause of day to day outages is largely invisible to most customers.
- The only choice in this survey is reducing. There is no option to maintain current levels. Being prepared to minimize the duration of an event should it happen is important.

End Users

- Major events cannot be reasonably predicted especially with global warming trends and more severe weather. The flexibility and the ability to react to the event is more important which will impact duration.
- Drag and drop does not work in my browsers.
- Consistent and reasonable Power Quality is a main element any reliable electricity supply.
- no
- Drag and drop does not work. most important reducting the number of day to day interruptions, reducing the durantion of day to day interruptions, reducing the duration of interruptions due to major events, reducing the number of interruptions due to major events, overall power quality.
- At [company] a consistent voltage supply with minimal swing from min to max is critical for our plant. It's fine to quote industry standard expectations, our expectations are higher than this.
- Unplanned outages whether day to day or major events have significant impacts on employee safety, the environment, neighbouring communities and profits. Our licence to operate is compromised.
- A one minute outage or a 30 minute outage will still cause over 2 hours of production loss.
- This question is like asking me do I prefer having my eardrum poked out or my finger nail pulled off - anything that brings our equipment down costs us a lot of lost production, lost material, and often lost instrumentation boards etc. Once we are down, whether the power comes back in 2 seconds or two hours is less important - we are often down for over a shift anyways.
- Not relevant. All equal.

Generators

- As long as we understand this is seen purely from me as a power producer. We don't rely on the grid for our internal stuff.
- On-peak periods is our main focus and need interruptions reduced or eliminated during the on-peak periods Monday thru Friday.
- Power quality is not a transmission issue and shouldn't be on the list. Frequency and duration of outages are the key. Due planning processes for planned events is critical.
- i understand we do not control the weather, goal is to reduce the impact on the utility

Investment Scenarios (1)

Q Please use this space to tell us why you placed the slider where you did
[asked of all respondents, n=103]

LDCs

- best balance of costs vs benefits
- This rate should still enable you to decrease the risk without a significant short term rate increase.
- I recognize HONI has very difficult choices to make. However, it is very difficult to support a transmission rate increase that is greater than 1.5 times CPI
- It combines all four scenarios into one with moderate rate increase, high reliability and moderature future increases.
- Ideally, the rate increase would be inflation plus some nominal percentage. However, if 3.3% results in a material decrease in service capability, this new information suggests that the next highest level of investment is appropriate, thereby putting this somewhere in between Scenarios C and D.
- decrease on reliability risk while levelling future rate increases.
- 1) Hydro One is inefficient and needs to sort out their internal processes and find greater efficiency.2) There is nothing in this plan for innovation. Why would they invest in Tx infrastructure without a plan to manage the two-way flow of electricity that distributed generation will bring in 10-15 years. The last thing anyone wants is billions of $ in distressed transmission assets.
- Low rates a priority and managed risks - information is imperfect and so the best investment is to get better data/information while you have the time to drive better investment outcomes while living within a cost affordability index. Are you getting the right bang for your investment today? That data was not made available - can you assume you will get more for the money you are investing?
- I would consider a point midway between scenario B and C, the point where risk is neither increasing or decreasing..
- Under your maintain current level you are showing a reduction in average percentage of key assets beyond normal life expectancy. how is this maintain? In addition, you are suggesting that to maintain current levels of expenditures you need a 5.1 % annual increase in rates. Why is it not at or below inflation? These various senerios don't seem to make sense when looking at the rates or risks shown
- This scenario keeps the transmission system at about the same health level as it is today and while the transmission rate increase is moderate, the overall bill impact is small and likely tolerable by most customers.
- Significant investments have been made over the last five years to allow for DG resources to be connected. My expectation is that the rate of investment can now be curtailed back some.
- The costs are a major input into these evaluations. A TS decommisioning was quoted at over $10M, transfer trip for a DG a few years ago was $180k is now being quoted at $400k, rebuilding a TS is being quoted at $38M. The choice is really C with an A rate increase.
- The system already has a health percentage of aged equipment and with the increasing reliance on the transmission system to achieve the government's environmental goals, reliability will only become more important.
- No choice made. Analysis simplistic. Need to look for alternative savings (OM&A) to offset cost of increased asset investments.
- Keep increases at inflation.

Investment Scenarios (2)

Q Please use this space to tell us why you placed the slider where you did
[asked of all respondents, n=103]

End Users

- Chose the middle, trying to find a happy medium, so that we try to fix the mess we are in efficiently and cost affective as possible. However the rate increases is to high but we can't keep delaying either creating a bigger problem for future etc
- maintaining the current level of investments will provide the planning and necessary funds for equipment is replace/upgrade as required to ensure reliability of power supply
- Good balance
- Reliability needs to improve but rate increases need to be balanced as it effects our operating costs
- To maintain a consistent cost(although increased) with a higher reliability.
- I am prepared to take on more risk as we get the cost envelop sorted out and I am not willing to accept that rates would only change from .11% to .46% between scenario's when costs to the public have been going up by double digits per year for many years. IN addition I am not prepared to accept that managing the rate of investment now will necessarily result in significantly higher future rates. The whole system has to take responsibility for the costs the public is struggling with NOW !
- Maintains the average percentage of key assets beyond expected service life constant.
- Preference would be investment close to scenario C but at lower transmission rate increase. i.e. Hydro One should look into improving its own efficiencies or finding ways to obtain the required funds to achieve scenario D or at minimum Scenario C's goals without significant increases to the transmission rates.
- The current level of reliability is acceptable therefore maintaining the status quo would seem appropriate.
- Reduces risk, reduces the number of assets beyond expected life, cost increase is high, moving to Scenario D does not reduce the risks that much more based to cost. Selecting Scenario A or B will put our distribution system at to high a risk.
- Transmission costs are already too high. More needs to be done to ensure the investment $$ are being spent wisely.
- Hydro One is unfortunately operating in one of the highest rate markets in North America. Normally higher increases could be tolerated, however with the current state of the electricity market reasonable rate increase are expected, even if it comes at the cost of degraded reliability. This is ultimately due to current and previous provincial governments however Hydro One is forced to take this under consideration.
- Internal savings and efficiencies must be considered (salaries) to minimize rate increases. Increases in the 2 to 3% range combined with internal savings should net to Scenario C. This should be the goal.
- It would appear that the infrastructure has not been maintained at the correct pace. A reduction now would jeopardize future reliability.
- Your reliability assessments are not credible - on the single circuit SAIDI you do not even know why the majority of the interruptions occurred - so how can you model accurate reliability assessments? Your question is the equivalent of asking "if I fall out of a boat, should I wait for help or try and swim for shore? Why not just climb back into the boat?" You are missing the third option. Ex: instead of flying helicopters to check lines, why not use drones whose flight controls are tied to a carrier signal on the power line itself - get creative with the regulatory guys and find a way to reduce the costs - this is what industry does ....How big a transformer can you put on a flatbed - can several (already on flat beds) be used for multi circuit reliability and in case of an emergency, pulled out to use elsewhere ..... what about a system (used in Europe) where if one phase goes out, the other two are (downstream) reconfigured to power all three lines - just with a reduced capacity, until repairs are made. etc - etc
- we're on unreliable lines so we'd like some investment in those lines under any scenario. some is more than what we've seen in recent years. with upward pressure on rates, we'd be hard pressed to call for much more reinvestment than B. I'm wondering about the capital estimates and whether or not there is any room for efficiencies within?
- Please lean on successful areas (provinces/states) that face the same pressure and show a marked improvement in Reliability and Quality and use that as a benchmark.
- Do not want to see any service supply or reliability deteriorate from the current state

Investment Scenarios (3)

Q Please use this space to tell us why you placed the slider where you did
[asked of all respondents, n=103]

Generators

- It meets many of the things and it's a subtantial capital investment, but it has a lot of things moving in the right way. Decrease in reliability risk, improvement in long-term reliability. Fairly level future rate increase.
- You should manage your business to be at or below the annual Canadian index price increase and still be reliable. Actual rates are already very high. We pay anywhere between $120-150/MW which is too high.
- Balance the annual rate increase based on risk.
- Scenario A seems the most favourable at this time; companies are very cost focus and margins are currently very tight.
- increased reliability, levelled rates
- Clever OEB type presentation Ontario in very fragile economic condition Just focus on cutting cost There is not as you imply direct correlation between cost reduction and reliability
- The reality is we have taken the cheap route and now the system needs to be upgraded and repaired. Best to pay and be done with it.
- The current situation is in part the result of a deliberate reduction in re-investment in the mid 1990's to mid 2000's which has resulted in equipment beyond service life. If reliability levels are to be maintained or improved, then a balanced and consistent approach is required.
- there is a lot of old components that need replacing already. reducing spent $'s will not enhance current performance
- We want a decrease in reliability risk and not too much increase in rates;
- I do not agree with Hydro One's premise that there should be increases in Hydro rates amongst all the options. Like any other business; Hydro One needs to improve how it runs its business; how it seeks innovative answers; how it can deliver the same or better service for less money. I fundamentally disagree with all the options above; Hydro One has to stop acting in a way that it think it is entitled to more money or else the lights go out; Hydro One needs to start thinking like all other businesses; get lean; lower costs; meet customer expectations. The people and businesses of Ontario shouldn't have to keep paying for Hydro One's excesses. Rates should be kept constant; and the service should improve for that cost moving forward.
- Best choice overall from reliability and long term cost perspective

Questions for LDCs (1)

Q Is there anything in particular you feel Hydro One can do better to help you meet your customers' needs?

[asked of all LDC respondents, n=28]

LDCs

- Improved Communication to LDC's on reliability issues
- more regular updates
- Mitigate short circuit constraints for generation connections.
- Harden the single circuit 115 kV D10H circuit that supplys Elmira TS. We have lost this supply twice in recent years during ice storm events.
- Nothing. They are doing a fine job at this point with regards to transmission
- Not really
- Invest strategically in infrastructure. Cap top 5 salaries of Hydro One staff (ie: CEO, CFO, etc.) for letting the system deteriorate to the point where it is right now.
- Increased pre-planning for joint investments with the LDCs. Improve project management to achieve project milestones on time. Better transparency of costs associated to projects requested by the LDC for Hydro One to complete.
- Improve its brand/reputation. When Hydro One "screws-up", it bring the reputation of the entire Ontario electricity sector down. This make working with my LDC's customers more difficult.
- no I currently do not have any issues especially with the people that I deal with
- Treat me like a customer - provide me with the level of data needed to manage my customers - often you will react to my customers who are mine and provide better information to them (cause of outage, expected duration, etc) than you do for me. Better collaboration between control centres - I bet you dont treat your Hydro OGCC the same way you treat other utility control centres.
- Assist with Power quality investigations.
- Better support at local level
- communication and coordination of TS work requires significant improvement
- Better planning of maintenance outage notifications. Costs need to stabilize while at the same time allow for development of new loads in rural areas at costs that are reasonable and not prohibitive. Don't try and push normal maintenance and replacement costs onto new customers.
- It would be helpful if Hydro One were able to provide more reasonable cost estimates for their work. In past years, Hydro One was know for high costs of work and had an active program to reduce their costs of doing business. That effort seems to have waned now and costs have gone back to levels that many customers feel are too high.
- LDC's and Hydro One need to be working in partnership not as competitors allowing for further cooperation and to paticipate in early consultation
- improve reliability in smaller rural communities, reduce engineering costs for distributed generation projects. reduce operating, maintenance and administrative costs as a whole and pass the saving onto the customer base.
- See the opening comments.
- Consider both the financial and reliability impact of your actions on our customers.
- regulate voltage better
- lower rates

Questions for LDCs (2)

Q Is there anything in particular you feel Hydro One can do better to serve the specific needs of First Nations and/or Métis communities?

[asked of all LDC respondents who serve First Nations and/or Metis communities, n=2]

LDCs

- No.
- The northern single circuit communities deserve more attention as they are more vulnerable in terms of supply and outage response.

Content Covered (1)

Q Was there any content missing that you would have liked to have seen included?
[asked of all respondents, n=103]

LDCs

- NO
- No mention of removing transmission constraints for distributed generation in our area
- None that can be recalled
- A section focused for the LDC to comment on joint projects.
- Innovation -- how is Hydro One being innovative?
- not at this time
- Yes - already told you your current performance on asset plans was missing, your risk management plans were missing, your productivity improvement plan to show what you get for the $ invested and how much more is expected so that I could "trade" off appropriately
- No.
- No

End Users

- More detailed breakdown of cost
- Cost reduction; show customers what you're doing to save money and find efficiency.
- Although hard to do, a break out of necessary upgrades based on affected areas of distribution, could potentially make justification higher.
- I simply don't agree with some conclusions and feel the analysis was skewed towards the higher investment options.
- It would be good to know what Hydro One is doing to improve its own efficiency in order to free up funds to cover some of the investments
- How to save in GA costs.
- None
- Overall Good Content.
- Results of benchmarking Hydro One with other North American utilities to compare fixed costs, maintenance spend, capital spend and other measures of productivity.
- What is the action plan for internal savings, efficiencies?
- Cost of service - you are an expensive service in an expensive province - if you are having trouble paying for the grid today, then how are you going to pay for it tomorrow when so many more industrial plants leave the province (and we are not investing in Ontario assets - just letting them run down to obsolescence - closures are coming).
- A breakdown of the "key assets" where the major investments are required

Content Covered (2)

Q Was there any content missing that you would have liked to have seen included?
[asked of all respondents, n=103]

Generators

- No
- No
- Some graphics may help. Circuit performance. A map of circuit performance - who is getting the best performance?
- No
- did not attend
- Graphs of last ten year cost and productivity info Benchmarking
- No
- Some metrics on resourcing required to achieve the goals, efficiency improvements.
- CIA, Connection Cost Estimate and work planning, timeline improvement
- I thought it was quite comprehensive for our purposes, but one aspect to add in for future may be interconnection process feedback.
- plan for increasing the amount renewable energy that can be connected
- I think there is an obvious outcome locked into the questions; whereby all answers involved increased funding. I think this is dishonest and lacks alignment with the people and businesses of Ontario that don't have such a luxury.

Outstanding Questions

Q Is there anything that you would still like answered?
[asked of all respondents, n=103]

LDCs

- No
- Nothing
- Not at this time
- no
- How is Hydro One going to improve productivity? What is process for managing staff / project teams in Northern Ontario?
- no
- When you are releasing the plans? Will there be any dialogue on rates and where will we get a chance to review tha comments?
- No.
- No

End Users

- Cyber security plans.
- Sufficient
- No
- See above
- How do you plan to improve reliability while decreasing costs - and if you are telling me that it can't be done, then in industry parlance "you're fired"!!

Generators

- No
- No
- No
- No
- did not attend
- Please ensure to pass on the current level and expectations of customer focus to new employees of HONI; communications is key and appreciation of the cost to customers when the grid is not available.
- NO just focus on cost reductions
- No
- i would like to be able to review and understand the Hydro outage summary. Why is it so cryptic, it should be very transparent and not require an interpreter.
- No
- Innovation and lean management of Hydro One to drive cost savings and improve performance.

Future Customer Engagements (1)

Q How would you prefer to participate in these engagements?
[asked of all respondents, n=103]

LDCs

- If my system would allow me, I would do it over the internet
- in person/email/webinars...but in person is always best
- Survey
- Proper engagement with the LDC community. We want Mayo to reach out to us (and not just to buy us). Come to the EDA and start a dialog with Ontario's LDCs.
- keep it the same as the current method works fine for me
- I would prefer the list of questions and answers fed back and how you respond differently to the critical questions and answers you are recieveing
- similarly with link again
- The survey works well. I have participated in previous in-person group sessions and found them informative as well. Perhaps a balance of alternating in-person with surveys would work.
- On line surveys are good
- I like the format, and the length.

End Users

- "1) Face-to-face feedback sessions.2) Workshops with similar industrial customers."
- Customers direct participation
- None
- Information sessions as well as surveys
- Suggest targets for productivity. H-1 should be looking to improve productivity in an effort to "live within its means" like all other businesses in Ontario - and ALL of H-1's customers - have to.
- None
- Surveys for a couple of years, face to face meetings every 3 years
- Survey is fine.
- Prefer on line surveys to telephone surveys.
- Not sure - maybe an interview would be better - tough to express yourself using words without conveying urgency or emphasis (for which the written word is not amenable - unless you are an accomplished author)
- Too much reading it was making me nod off
- survey was a good vehicle
- Asking to weigh items that are really equal seems like a waste of time.
- Same as this

Future Customer Engagements (2)

Q How would you prefer to participate in these engagements?
[asked of all respondents, n=103]

Generators

- Web based engagement
- We appreciate the opportunity to participate in the engagement and look forward to similar opportunities in the future. We believe the online survey tool is an appropriate means to do so.
- This format is fine.
- did not attend
- AS OEB has mandate over rates my input is of no value
- By on line survey
- I think the online survey is a good method.
- focus more on embedded generation with renewables
- The current method is fine.

Appendix 1.2
The Survey

Welcome to Hydro One's transmission customer engagement survey.

Why are we here?

Hydro One is starting its planning process for the 2019-2023 plan. As you may be aware, Hydro One currently has an application before the Ontario Energy Board to cover the 2017-2018 period. However, transmission systems have long planning horizons and Hydro One needs to start now to prepare the business plan for 2019-2023. For the purpose of getting your views on the outcomes and priorities that matter to you, Hydro One has used this 2017-2018 application as its starting-point. **See the "Additional Information" document for more information about Hydro One's planning process.**

Hydro One engages with its transmission customers through key account mangers, regular surveys, and various planning processes. Now, Hydro One needs to hear from you about the outcomes you care about, as well as the pace and mix of investments that you would like to see included in the plan. Your views are a key input as Hydro One sets priority outcomes in its 2019-2023 business plan and makes choices about the investments that will be included in that plan.

Your privacy will be protected.
Hydro One has engaged an independent research firm, Innovative Research Group, to document your views. All individual responses will be confidential. Your results will be combined with others in any reports. **See the "Additional Information" document to read our privacy policy.**
Throughout this survey, you will see the following: 📖
This is an indication that a word or phrase appears in the glossary at the end of this document.

WE APPRECIATE YOUR PARTICIPATION IN THIS SURVEY, AS THE RESULTS MAY IMPACT YOUR RATES AND THE EXPECTED RELIABILITY OF THE TRANSMISSION SYSTEM.

[LDCs only]
As a distributor, please respond to the questions in this survey with your customers in mind. Your feedback should be made with consideration to your customers' needs.

What we are consulting about?

The Hydro One planning process generates a number of potential capital investments📖. Some of these investments are required to comply with the various standards and regulations that apply to Hydro One's business. But many investments have a discretionary factor, at least in terms of timing.

There are three key questions about Hydro One's potential capital investments at the core of this customer engagement:

- **What outcomes should Hydro One focus on as it decides which investments come first?**
- **How should Hydro One pace its investments in the transmission system over the long run?**
- **What is the preferred balance between reliability and the amount customers are willing to pay?**

When the plan is submitted, Hydro One will share with you both a summary of what customers said in this survey and how Hydro One responded to that input.

SURVEY RESPONSE OPTIONS:
This survey takes about 20 minutes to complete.
You can complete the survey online or, if you prefer, we can schedule a one-on-one interview either in person or by phone. If you prefer a live interview, please contact Susan Oakes at (416) 642-6341 or soakes@innovativeresearch.ca to arrange a time that is convenient for you.

To ensure your comments are considered in the planning process we need your responses by June 9, 2017.

There are *Additional Information* links throughout this workbook.
The questions have been presented with the most important information one might need to make a decision. While many transmission customers are very familiar with the transmission system, there may be specific areas where additional information would help you better answer the questions. As you go through this survey, you will find links to additional information you may find useful. You may need to enable pop-ups on your browser to enable this feature. **You can also see the "Additional Information" document to download the complete background package with all the additional information if you wish.**

The most important part of this workbook is the survey questions.
Utilities are expected to develop a genuine understanding of their customers' needs and preferences and integrate them into their plans. As such, the goal of this workbook is to understand the general priorities and criteria you would like Hydro One to use when making key business decisions. While your view may not always align exactly with the available options, please select the one that is closest. If you truly aren't sure, select the "don't know" option.

You will also find comment boxes throughout the survey. The comment boxes are there to provide you with the opportunity to expand on your answer if needed.

Confidential and Forward Looking Information

CONFIDENTIAL INFORMATION

In this survey, “Hydro One” or “the Company” refers to Hydro One Networks Inc. and its affiliates, taken together as a whole.

Hydro One is providing the information contained in the following survey on a confidential basis in order to solicit your feedback on customer outcomes and potential alternate investment scenarios and their expected impact on the reliability of our transmission system. The feedback from this customer engagement will be considered when making regulatory filings. Any information concerning Hydro One provided as part of this survey should not be disclosed except as necessary within your corporation in order to provide meaningful feedback.

You should not trade in securities of Hydro One Limited or Hydro One Inc. based on any of the information contained within this survey and should not use the information for any other purpose.

In this survey, all amounts are in Canadian dollars, unless otherwise indicated. Any graphs, tables or other information in this survey demonstrating the historical performance of Hydro One are intended only to illustrate past performance and are not necessarily indicative of future performance.

Forward-Looking Information

This survey contains “forward-looking information” within the meaning of applicable Canadian securities laws. Forward-looking information in this survey is based on current expectations, estimates, forecasts and projections about Hydro One’s business and the industry in which Hydro One operates and includes beliefs of and assumptions made by management. Such statements include, but are not limited to: statements regarding expected or projected capital and development expenditures, the timing of these expenditures and the Company’s investment plans; the use of customer feedback from the engagement process and its impact on the Company’s investment plans; the impact of future investments on customer risk, reliability performance and risk, and service interruptions; statements about asset condition, the average ages of critical assets, and their future expected condition; statements about types of asset replacements and their expected associated costs; and statements about illustrative scenarios and their impact on capital spend, expected outcomes, rates, changes in risk profile according to asset class, and increased or decreased system risk impact.

Words such as “aim”, “could”, “would”, “expect”, “anticipate”, “intend”, “attempt”, “may”, “plan”, “will”, “believe”, “seek”, “estimate”, “goal”, “target”, “project” and variations of such words and similar expressions are intended to identify such forward-looking information. These statements are not guarantees of future performance and involve assumptions and risks and uncertainties that are difficult to predict. Therefore, actual outcomes and results may differ materially from what is expressed, implied or forecasted in such forward-looking information. Hydro One does not intend, and it disclaims any obligation to update any forward-looking information, except as required by law.

The forward-looking information in this survey is based on a variety of factors and assumptions. Actual results may differ materially from those predicted by such forward-looking information. While Hydro One does not know what impact any of these differences may have, Hydro One’s business, results of operations and financial condition may be materially adversely affected if any such differences occur. Factors that could cause actual results or outcomes to differ materially from the results expressed or implied by forward-looking information are: the risk that previously granted regulatory approvals may be subsequently challenged, appealed or overturned; the risk of public opposition to and delays or denials of requisite approvals and accommodations for the Company’s planned projects; the risk that the Company is not able to arrange sufficient cost-effective financing to fund capital expenditures; the risk that the Company may not be able to execute plans for capital projects necessary to maintain the performance of the Company’s assets or to carry out projects in a timely manner; the risk that the Company’s Board of Directors may not approve the projected expenditures; and the risk that the regulator may alter or deny approval for requested investments and recoverability in rates.

How well is Hydro One meeting your needs?

Hydro One Inc. owns and operates a 30,000 circuit 🕮 km high-voltage 🕮 transmission network that includes 306 transmission stations and transmits 98 percent of Ontario's electric capacity.

For more information about Hydro One's transmission system, the standards it must meet, its activities, and reliability statistics, See the "Additional Information" document.

Questions

1. **How satisfied are you with the overall performance of Hydro One in providing your business with electricity?**
   - ❍ Very satisfied
   - ❍ Somewhat satisfied
   - ❍ Somewhat dissatisfied
   - ❍ Very dissatisfied
   - ❍ Not sure / Don't know

2. **Is there anything in particular you feel Hydro One can do better?**
   Please fill in your response below

   - ❍ Not sure / Don't know

3. **How do you know if Hydro One is doing a good job for your business?**
   Please fill in your response below

   - ❍ Not sure / Don't know

Customer Outcomes

Hydro One has to make choices in its planning, and it needs to know what is most important to you. Hydro One is responsible to the Ontario Energy Board to show how its plans provide the cost effective delivery of outcomes that customers value. **To learn more about the customer engagement process and the Ontario Energy Board's requirements, See the "Additional Information" document.**

In reviewing its previous customer engagement research and in discussions with customer-facing Hydro One staff including its Key Account Managers, Hydro One has developed a tentative list of outcomes for your review. This survey is going to ask you if anything is missing from that list, how important each outcome is to you, and which outcomes are most important compared to the others.

This section will ask you to rate how important the outcomes are to you and to share your thoughts on how Hydro One could do better. You will also have an opportunity to add any outcomes you feel are missing.

We will be asking you about the following seven outcomes:

- Customer Service
- Environmental Stewardship
- Outage Restoration
- Power Quality
- Productivity
- Reliability
- Safety

To rate the importance of an outcome, please select a point on the slider below each description. If there are areas that you don't have an opinion on, please select the "don't know" option.

Safety

Eliminating and mitigating risk to public and employee safety in the operation of the transmission system. **For additional information on Hydro One's performance to date, See the "Additional Information" document.**

4. How important an outcome is safety?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Productivity

Implementation of new technologies and processes to enable operational efficiencies in the planning and execution of work programs aimed at reducing costs and more efficient use of resources. Hydro One understands that customers expect it to look first for internal savings before asking for any additional rates.

5. How important an outcome is productivity?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Reliability

Maintaining the uninterrupted operation of the transmission system for all customers by sustaining the existing assets, replacing assets that are in poor condition and addressing transmission system performance outliers 🕮. **For additional information on Hydro One's performance to date, See the "Additional Information" document.**

6. How important an outcome is reliability?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Outage Restoration

Provisions to ensure timely and efficient response to failures, unplanned outages 📖, or imminent risks to the transmission system to minimize customer interruption and prompt restoration to normal operating conditions.

7. How important an outcome is outage restoration?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Power Quality

Delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform 📖. Assessing customer concerns and implementing mitigation plans to address and rectify power quality issues for transmission connected customers.

8. How important an outcome is power quality?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Customer Service

Enhancements to the transmission customer experience such as outage planning and operational communications, timely estimates and project execution for transmission connected customers. **For additional information on Hydro One's performance to date, See the "Additional Information" document.**

9. How important an outcome is customer service?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Environmental Stewardship

Identifying potential risks to the environment as a result of emissions from Hydro One's own operations, and investing in mitigation strategies to ensure compliance with all applicable environmental regulations consistent with the Government of Ontario and the Government of Canada.

10. How important an outcome is environmental stewardship?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Additional Outcomes

Are there any outcomes we missed? Please use the boxes below to add them, and then the slider to rate their importance.

11a. Suggested Outcome 1:

11b. How important is this outcome to you?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

12a. Suggested Outcome 2:

12b. How important is this outcome to you?

Not at all important — Extremely important

0 — 10

❍ Not sure / Don't know

Comments

13. Do you have any specific comments or suggestions regarding any of the seven outcomes that you just rated or any additional outcomes you added?

- Customer Service
- Environmental Stewardship
- Outage Restoration
- Power Quality
- Productivity
- Reliability
- Safety

Please fill in your response below:

Customer Outcomes

Top Priorities

While all the outcomes listed are important to many customers, planners set priorities among different outcomes. The purpose of this section is to help Hydro One set priorities as it prepares its business plan. Which priorities should they focus on first?

For a list of outcome definitions, See the "Additional Information" document

Please rank your top priorities from the list below.

Drag and drop the priorities in order, starting with the priority most important to you, followed by the second most important, then the third most important, and so on. Please try to rank all listed priorities:

Priorities	Top Priorities
Safety	
Productivity	
Reliability	
Outage Restoration	
Power Quality	
Customer Service	
Environmental Stewardship	

Comments:

Making Choices: Pace of Investment

When Hydro One replaces equipment in declining health, it has some flexibility in its pacing. **For more information on the health of Hydro One's assets, See the "Additional Information" document**

We would like to understand your general views on the appropriate pacing of Hydro One's investments over the next 15 – 20 years. Hydro One can front load its capital investments, it can spread them evenly over time, or it can delay its investments.

Front-loading investments would provide some benefits in terms of more connection capacity 🕮, decreased equipment failures, increased reliability, and improved productivity and quality. This would mean higher rate increases now but lower rate increases in the future.

Spreading evenly over time means some benefits are delayed but some long term savings are secured and it is more efficient in terms of staffing. Rate increases would increase at a stable level. Asset deployment costs would likely be lower using this more stable pacing philosophy.

Given the current health and demographics of the system, Hydro One can delay investments further until declining equipment conditions threaten Hydro One's ability to meet power reliability requirements. Reliability would still meet minimum standards but customers would likely experience more interruptions 🕮 than today. Rates increases would be relatively low for several years but increase at a steeper rate in the future.

Bearing in mind the trade off between immediate rate impact, long term rate impacts and system benefits, which approach best reflects how you feel Hydro One should pace the work required to renew the system over the next 15-20 years?

- ❍ Invest now, higher rates in short term, lower increases in future
- ❍ Spread investments out, stable rate increases
- ❍ Delay investments, lower rates in short term, higher increases in future
- ❍ It depends
- ❍ Not sure / Don't know

Why do you prefer the scenario you chose over the other two scenarios?

What does it depend on?

Reliability

We are now going to move on to the topic of reliability. The term “reliability” means different things to different people, so before we move on, please describe what reliability means to your organization.

When you are talking about transmission reliability, what does that mean to your organization?

Making Choices: Reliability

Reliability has a specific meaning in electricity, but often when customers talk about reliability, they are also talking about power quality (defined as delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform). Below is a list of five items that are often included when people talk about reliability. In addition to power quality, when people raise concerns about interruptions they often draw a distinction between interruptions that are experienced during normal day-to-day operations versus interruptions that occur during major events such as severe storms.

Please rank the following reliability items in order of which are most important to your organization.
Drag and drop the items in order, starting with the item most important to you, followed by the second most important, then the third most important, and so on. Please try to rank all items:

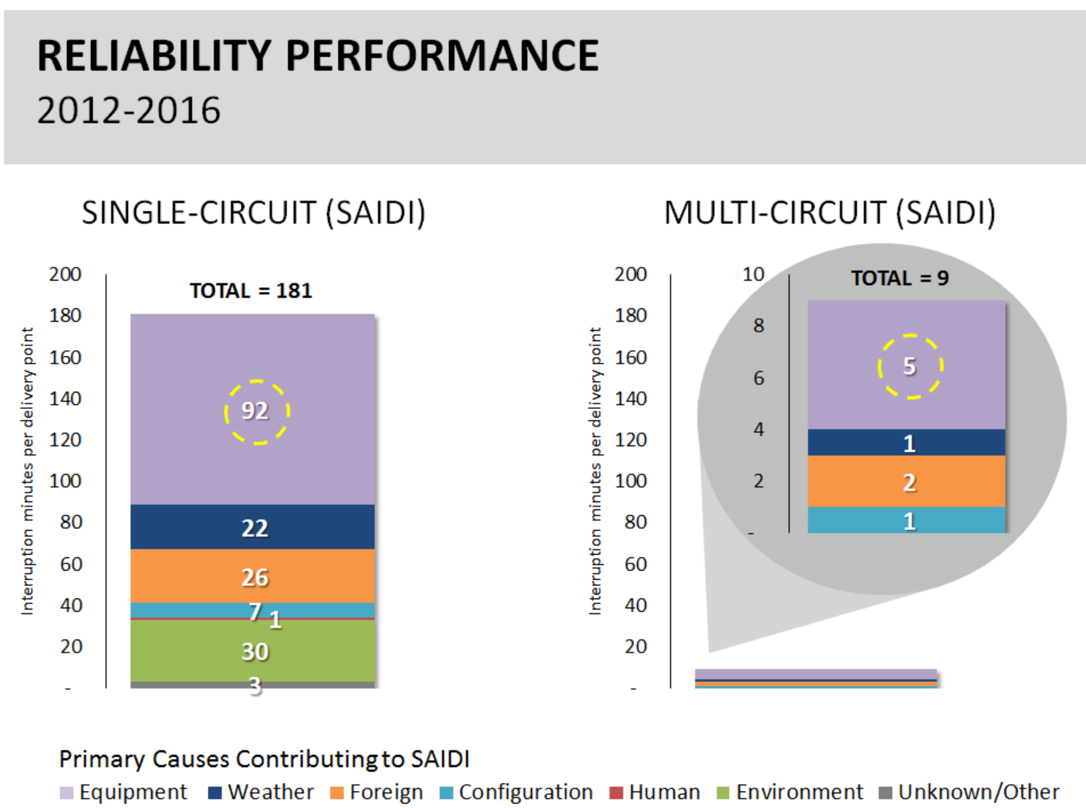
Reliability Items	Importance
Reducing the number of day-to-day interruptions	
Reducing the number of interruptions due to major events	
Reducing the duration of day-to-day interruptions	
Reducing the duration of interruptions due to major events	
Overall power quality	

Comments: Is there anything else you would like to add on the topic of reliability?

Making Choices: Reliability Trade-Offs

Understanding reliability is important when assessing the trade-offs facing Hydro One. To help understand the impact of investment decisions on reliability, Hydro One as developed a metric called “reliability risk”. No one knows for sure when a specific piece of equipment will fail, but we do know how likely asset failure is for groups of equipment in specific conditions. This means we can project a likely risk of failure for a given pool of assets.

When it comes to transmission reliability, Hydro One has performed well compared to Canadian peers. The key strategy employed to avoid customer interruption in the transmission system is redundancy 🕮. Most of the transmission system has been built with at least one redundant circuit for every operating circuit. The chart below shows the benefit of redundancy as customers on single circuit 🕮 systems experience much more time (shown below as System Average Interruption Duration Index or SAIDI) 🕮 without power than customers on multi-circuit systems 🕮.



See the "Additional Information" document to read the definitions of these categories

Transmission Customer Engagement

Delaying capital spending will, in time, result in more and more equipment failures. While redundancy often prevents these failures from leading to customer interruptions, equipment failures will leave multi-circuit customers at risk of the single-circuit reliability experience. Reliability risk provides a leading indicator of the expected impact of allowing the condition of equipment in the transmission system to decline.

Making Choices: Illustrative Scenarios

Now we would like to take one last look at the core trade-offs Hydro One must make as it begins its business planning for 2019 to 2023:

- the balance between the level of investment and system reliability, and
- the timing of those investments.

To help understand your priorities, Hydro One has developed four illustrative scenarios. The specific priority of investment items in these scenarios is based on the priorities used in Hydro One's proposal currently before the Ontario Energy Board. While those priorities may change based on your earlier feedback, these scenarios are illustrative of the impacts of various spending levels.

In considering these scenarios, please be advised that all figures are intended as approximate, and are not intended to be relied upon as exact.

These scenarios focus on the trade-offs between the pace of investment, reliability, and future rate increases. The higher the level of investment, the lower the reliability risk 🕮, and vice-versa. As you consider these illustrative scenarios, please bear in mind that your rates can also be impacted by changes in load forecast and electricity prices. All scenarios assume an Operations, Maintenance, and Administration (OM&A) expense percentage increase that is held to less than inflation.

By preparing and providing these illustrations, Hydro One makes no representation that it will select one as its plan before the Ontario Energy Board.

Transmission Customer Engagement

Please read each scenario to understand how different investment levels impact key outcomes. You can choose one of these scenarios, a point between these scenarios or a point above or below these scenarios. There is a follow-up question that allows you to discuss the factors that you considered in making your choice. Your comments will help us better understand the outcomes you value.

These descriptions refer to "key assets" 🕮 which are conductors 🕮, circuit breakers 🕮 and transformers 🕮, as their failure is most likely to impact system reliability.

Scenario A: Limited investment

- Capital investment 🕮 focused on regulatory requirements and customer demand projects, such as new connections
- Sustainment capital 🕮 limited to replacing assets subject to imminent failure; no proactive sustainment investment
- The percentage of key assets beyond Expected Service Life 🕮 will increase from 21% in 2019 to 29% in 2023, increasing expected future investment requirements
- Total 5 year Capital Investment Plan: $1.8 B
- Average Annual Transmission Rate Increase: 1.3%

Scenario B: Decrease in current level of investment

- Capital investment 🕮 reduced compared to plan filed with the Ontario Energy Board in May 2016
- Spending on sustainment 🕮 of key assets deferred to future years
- Contains lower levels of investment in productivity and fewer strategic investments designed to mitigate future rate impacts (e.g., tower coating)
- The percentage of key assets beyond Expected Service Life 🕮 increases from 21% in 2019 to 26% in 2023, increasing expected future investment requirements and expenses
- Additional capital in Scenario B as compared to Scenario A focuses on replacing assets in poorest condition, resulting in a significant reduction in reliability risk 🕮
- Total 5 year Capital Investment Plan: $4.3 B
- Average Annual Transmission Rate Increase: 3.3%

Transmission Customer Engagement

Scenario C: Maintain current level of investment

- Extends investment plan in rate application currently before the Ontario Energy Board to 2023
- Maintains current level of sustainment capital investments affecting key assets
- Percentage of key assets beyond Expected Service Life decreases from 21% in 2019 to 19% in 2023, decreasing expected future investment requirements
- Incorporates strategic investments that mitigate future rate impacts, such as tower coating
- Total 5 year Capital Investment Plan: $6.6 B
- Average Annual Transmission Rate Increase: 5.1%

Scenario D: Increase beyond the current level of investment

This plan contains all investments in Scenario C, with addition of:

- Additional sustainment capital focused on key assets
- As a result, the percentage of key assets beyond Expected Service Life decreases from 21% in 2019 to 17% in 2023, decreasing expected future investment requirements
- While the above investments benefit all customers to some degree, this scenario also increases capital to add redundancy to worst performing single circuits in system, benefiting a very small portion of customers in a significant way
- Total 5 year Capital Investment Plan: $7.4 B
- Average Annual Transmission Rate Increase: 5.6%

Exploring Trade-offs Using Illustrative Scenarios

Below is a chart summarizing all the scenarios from the previous page and their implications. As we mentioned these examples are meant to illustrate the impacts of different levels of investment on current and future rate increases and system reliability.

You will note that the two middle scenarios, B and C, offer a relatively small change in reliability risk, but moving from B to C offers significant improvements in long-term reliability. The key difference between B and C is that B has larger future increases, while C has level future rate increases. The big differences in reliability are in scenarios A and D. Moving from A to B creates a significant decline in reliability risk. Moving from scenario C to D generates both a long term reliability benefit and targeted reliability improvements for a small group of customers.

As noted earlier, by offering these illustrative scenarios, Hydro One is not committing to any of them; their purpose is to help Hydro One understand what you as a customer value. When Hydro One makes its Ontario Energy Board filing, Hydro One will incorporate feedback received through this process, but does not commit to pursuing any one of these illustrative scenarios.

Below the chart is a slider which represents the range of potential approaches Hydro One can take. On the far left is lower investment, lower short-term rates, lower reliability, and higher anticipated future increases. On the far right is higher investment, higher short-term rates, higher reliability, and lower anticipated future increases. Please use the slider to indicate what approach you think Hydro One should take. Hydro One will use the results of this exercise as a directional indicator of the route customers want to go.

NB: The location on the slider does not correlate directly with potential rate increases. (For example, while the physical distance between scenarios B and C is the same as between C and D, the impact on reliability, rates and other outcomes is very different).

See the "Additional Information" document to view a larger and more detailed version of this table.

Illustrative Scenarios				
	A: Limited investment	**B: Decrease in current level of investment**	**C: Maintain current level of investment**	**D: Increase beyond the current level of investment**
5 Year Capital Investment 🕮	$1.8 B	$4.3 B	$6.6 B	$7.4 B
Reliability Risk🕮	Increase in risk ~30%	Increase in risk ~10%	Decrease in risk ~10%	Decrease in risk ~15%
Long-term Reliability Impact	↓	↓	↑	↑*
Average Percentage of Key Assets Beyond Expected Service Life 🕮 by end of 2023 (21% in 2019)	29%	26%	19%	17%
Impact on Future rates	Significantly higher future rate increases	Higher future rate increases	Level future rate increases.	Slightly lower future rate increases.
Average Annual Total Bill Impact – Transmission Connected Customer	0.11%	0.27%	0.42%	0.46%
Average Annual Transmission Rate Increase	1.30%	3.30%	5.10%	5.60%

* Improvement in overall long term reliability and significant performance improvement for small number of customers connected to the worst performing circuits.

Thinking of all the considerations outlined, please choose a point along the line below that you believe strikes the right balance between rates and outcomes. (Remember you can choose a point located between scenarios or directly aligned with them).

Scenario A | **Scenario B** | **Scenario C** | **Scenario D**

Lower increases now
Higher future increases
Lower reliability

○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○ ○

Higher increases now
Lower future increases
Higher reliability

Questions for LDCs

Local distribution companies have unique needs that often differ from other transmission customers. On this page we'll explore:

Is there anything in particular you feel Hydro One can do better to help you meet your customers' needs?

- ❍ Don't know / Not sure

Does your company provide electricity to First Nations and/or Métis communities?

- ❍ Yes
- ❍ No
- ❍ Don't know / Not sure

Is there anything in particular you feel Hydro One can do better to serve the specific needs of First Nations and/or Métis communities?

- ❍ Don't know / Not sure

Were your responses to this survey informed by your own customer engagement activities for the purposes of a rate application, or by any other customer research?

- ❍ Yes
- ❍ No
- ❍ Don't know / Not sure

How did we do?

Overall Impression: What was your overall impression of the Transmission Customer Engagement?

- ❍ Very positive
- ❍ Somewhat positive
- ❍ Neither positive nor negative
- ❍ Somewhat negative
- ❍ Very negative
- ❍ Don’t know / Not sure

Volume of Information: Did Hydro One provide too much information, not enough, or just the right amount?

- ❍ Too much information
- ❍ Not enough
- ❍ Just the right amount
- ❍ Don’t know / Not sure

Content Covered: Was there any content missing that you would have liked to have seen included?

- ❍ Don’t know / Not sure

Outstanding Questions: Is there anything that you would still like answered?

- ❍ Don’t know / Not sure

Suggestions for Future Customer Engagements: How would you prefer to participate in these engagements?

- ❍ Don’t know / Not sure

If you have any additional questions or comments about Hydro One’s business plan or customer engagement, email: **Spencer.Gill@HydroOne.com.**

Next Steps

Thank you for completing the Transmission Customer Engagement. Your responses have been recorded.

Upon the conclusion of the survey, INNOVATIVE Research Group will compile the results and provide a report to Hydro One.

Hydro One will review the report as it reviews its priority-setting processes and determines the recommended level and pace of investment in its updated Transmission System Plan.

When Hydro One files the Plan in its next Ontario Energy Board application, it will share with you both a summary of what customers said in this survey, and how Hydro One responded to that input.

Thank you for your time.

Glossary

Capital Investment: Money used by a business to purchase fixed assets, such as land, machinery, or buildings.

Circuit: An electrical connection involving metallic conductors that transmits electricity between 2 points.

Circuit Breaker: A switching device for that stops or allows the flow of electricity between electrical equipment.

Conductors: A metallic wire that conducts electricity.

Connection Capacity: Hydro One's ability to add new customers and/or additional load to the transmission system.

Customer Service: Enhancements to the transmission customer experience such as outage planning and operational communications, timely estimates and project execution for transmission connected customers.

Delivery Point: The point of supply where the energy from the system is transferred to customers. This point is generally taken as the interface between utility-owned equipment and the customer-owned equipment.

Expected Service Life: The average time in years that an asset can be expected to operate under normal system conditions.

End of Life: the likelihood of failure, or loss of an asset's ability to provide the intended functionality, wherein the failure or loss of functionality would cause unacceptable consequences.

Frequency Deviations: Fluctuations beyond the normal operating frequency range.

High-Voltage Transmission Network: Interconnected circuits that operate at 115kV and higher voltage.

Interruption: A stop in the flow of electricity to a customer.

Key Assets: Major types of transmission assets defined as transformers, circuit breakers and conductors.

Long-Term Reliability: Reliability performance beyond the 5 year rate filing period.

Multi-Circuit Systems: Systems where power delivery points are supplied by more than one circuit.

Outage: Unavailability of electrical equipment due to disturbances, equipment maintenance, or equipment malfunction. Outages do not necessarily lead to interruptions for customers if there are backup or redundant facilities to maintain electrical supply.

Outage Restoration: Provisions to ensure timely and efficient response to failures, unplanned outages, or imminent risks to the transmission system to minimize customer interruption and prompt restoration to normal operating conditions.

Outliers: Individual assets or sets of assets whose performance is significantly different than the average performance of the system as a whole.

Power Quality: Delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform. Assessing customer concerns and implementing mitigation plans to address and rectify power quality issues for transmission connected customers.

Productivity: Implementation of new technologies and processes to enable operational efficiencies in the planning and execution of work programs aimed at reducing costs and enabling more efficient use of resources.

Redundancy: The inclusion of duplicate components to the system so that delivery points have multiple simultaneous connections. The purpose is to reduce the possibility of interruption in case of component failure.

Reliability: Maintaining the uninterrupted operation of the transmission system for all customers by sustaining the existing assets, replacing assets that are in poor condition and addressing transmission system performance outliers.

Reliability Risk: An index that provides leading directional indication of overall system reliability performance based on probabilistic risk of asset failures.

Safety: Eliminating and mitigating risk to public and employee safety in the operation of the transmission system.

Short-Term Reliability: Reliability performance within the 5 year rate filing period.

Single Circuit Systems: Delivery points that rely upon one circuit for the delivery of power. If that circuit fails then power is interrupted.

Sustainment Capital: Capital Investments made in order to maintain the current expected level of functionality and capability of system.

System Average Interruption Duration Index (SAIDI): The average outage duration for each customer served.

Transformer: An electric power equipment that changes the electricity voltage level. In Ontario, the transmission level voltage are typically transformed from 500kV to 230kV and 230kV to 115kV. To supply customers, 115kV and 230kV transmission voltages are transformed to distribution level voltages.

Transmission Stations: An electrical facility that connects a number or transmission circuits and transformers and performs a “hub” function for the flow of electricity across a region.

Transmission System Performance Outliers: Individual assets or sets of assets whose performance is significantly different than the average performance of the system as a whole.

Voltage Waveform: The shape of the 60Hz voltage curve observed at the supply point.

The Customer Engagement Process

Hydro One's investment plan for 2019-2023 will identify, prioritize and schedule the investments made in its system. The customer engagement process will ensure that the investment plan considers and reflects the needs and preferences of Hydro One transmission customers by achieving a balance between managing reliability risk, service and cost. This investment plan will be a key component of Hydro One's transmission rate application to the OEB in the spring of 2018. As a part of its submission to the OEB, Hydro One must demonstrate that its investment plan considers the needs and preferences of its transmission customers with regard to trade-offs between outcomes, costs and pace of investment. This approach is consistent with the OEBs Renewed Regulatory Framework.

The OEB's "**consumer-centric**" *Renewed Regulatory Framework for Electricity* (RRFE) shifts the focus from utility cost to value to customers. A key requirement the rate application process includes documenting the **active engagement** between utilities and their customers. Utilities are now required to demonstrate services are provided in a manner that responds to identified customer **preferences** and **needs**.

Below are quotes taken from the OEB's Rate Handbook outlining expectations for utilities:

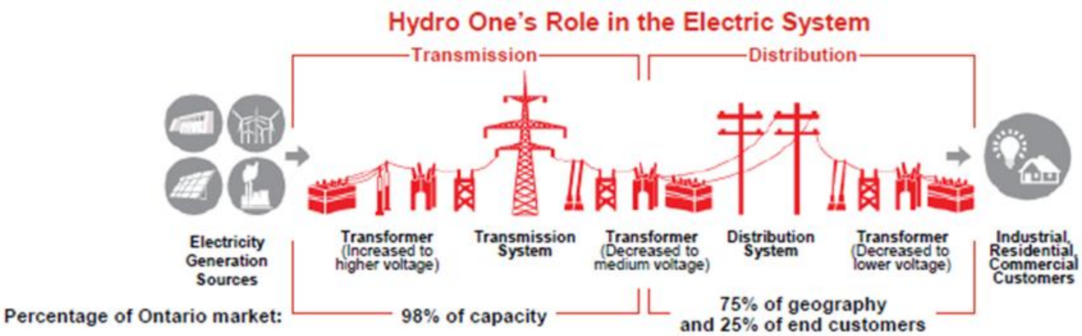
- "A utility is accountable for identifying specific outcomes valued by its customers and explaining how the utility's plans and proposed expenditures deliver those outcomes."
- "Outcomes are not activities such as the rebuilding of a pole line, but rather the qualitative expression of the utility's goals and objectives."
- "The outcomes should demonstrate the value proposition for customers and/or public policy goals."
- "Effective outcomes, in combination with the materiality thresholds, will allow the OEB to focus its assessment on results that drive value for customers."
- "The OEB has set four categories of outcomes through the RRF: customer focus, operational effectiveness, public policy responsiveness, and financial performance. Utility outcomes should link directly to one or more of these categories and be chosen to illustrate the benefits expected from key programs the utility is proposing."

All transmission-connected customers will have an opportunity to provide input that will support the development of the investment plan. Customers can provide their input by completing this online survey, or they may request an interview to be conducted in-person or by telephone.

Hydro One System Overview

Hydro One owns and operates an over 30,000 circuit km high-voltage transmission network, including 306 transmission stations, transmitting 98 percent of Ontario's electric capacity based upon revenue approved by the OEB, and an approximately 123,000 circuit km low voltage distribution network. It serves 75 percent of the geography of the province and more than 1.3 million residential and business customers.

Hydro One transmits high-voltage electricity from nuclear, hydroelectric, natural gas, wind and solar generation sources to local distribution companies and to directly connected industrial customers across Ontario.



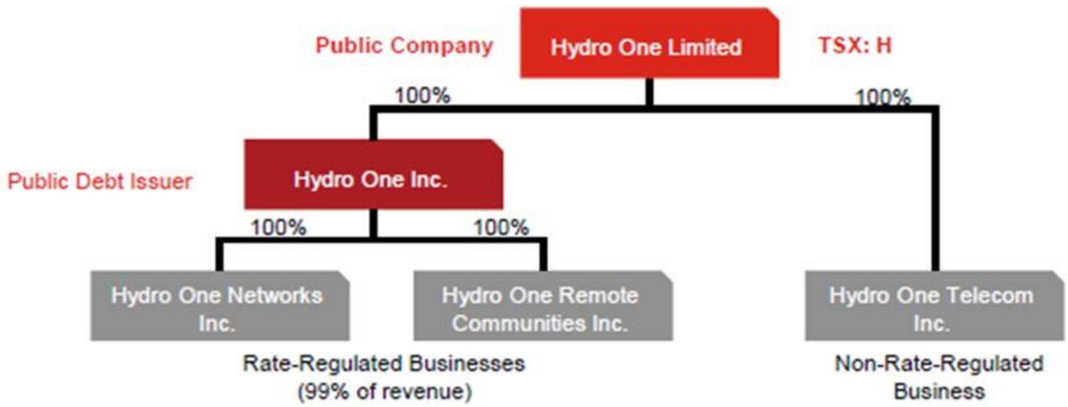
Hydro One's transmission assets can be divided into three main categories:

- Transmission stations: Used for the delivery of power, voltage transformation and switching, the stations serve as connection points for both customers and generators.
- Transmission lines: Bulk transmission lines deliver power from generating stations or connections to receiving terminal stations. Area supply lines take power from the network and transmit it to customer supply transmission stations at customer load centres.
- Network operations: The Ontario Grid Control Centre manages all of Hydro One's transmission and sub-transmission operations through a network of control, monitoring and communications equipment.

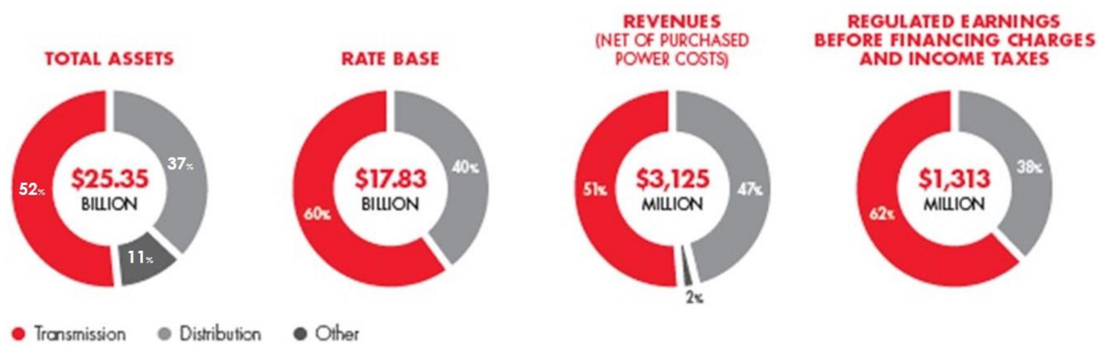
Hydro One's transmission business serves 44 Local Distribution Company (LDC) customer accounts, 87 large directly connected industrial customer accounts, and 126 generator customer accounts.

The assets in the Hydro One transmission system alone represent about $13 billion in net book value. Hydro One Limited became a public company coincident with its initial public offering in November 2015, and its common shares are listed on the Toronto Stock Exchange (TSX: H).

Hydro One's ownership structure:



Hydro One Limited's Financial Details:



Regulatory Stakeholders

Hydro One must meet the compliance requirements of six regulatory stakeholders: the Ontario Ministry of Energy, the Ontario Energy Board (OEB), the Independent Electricity System Operator (IESO), the National Energy Board, the North American Electric Reliability Corporation (NERC), and the Northeast Power Coordinating Council.

Organization	Who / What
Ontario	**Who:** Provincial Government, Ministry of Energy **What:** Policy, legislation, regulations
Ontario	**Who:** Ontario Energy Board (OEB) **What:** Independent electric utility price and service quality regulation
ieso Power to Ontario. On Demand.	**Who:** Independent Electricity System Operator **What:** Wholesale power market rules, intermediary, North American reliability standards
Canada	**Who:** National Energy Board **What:** Federal regulator, international power lines and substations
NERC North American Electric Reliability Corporation	**Who:** North American Electric Reliability Corporation **What:** Continent-wide bulk power reliability standards, certification, monitoring
Northeast Power Coordinating Council	**Who:** Northeast Power Coordinating Council **What:** Northeastern North American grid reliability, standards, compliance

Hydro One's Investment Planning Process

Hydro One must decide what comes first among specific investments. While Hydro One operates within standards that are dictated by various regulators, including the Ontario Energy Board and the North American Electric Reliability Corporation (NERC), Hydro One still has a range of choices in setting priorities among investments.

During Hydro One's planning process, candidate investments are identified by Hydro One's engineers and business planners. They take a variety of factors into account including asset needs, compliance, customer requests, regional needs, productivity and safety.

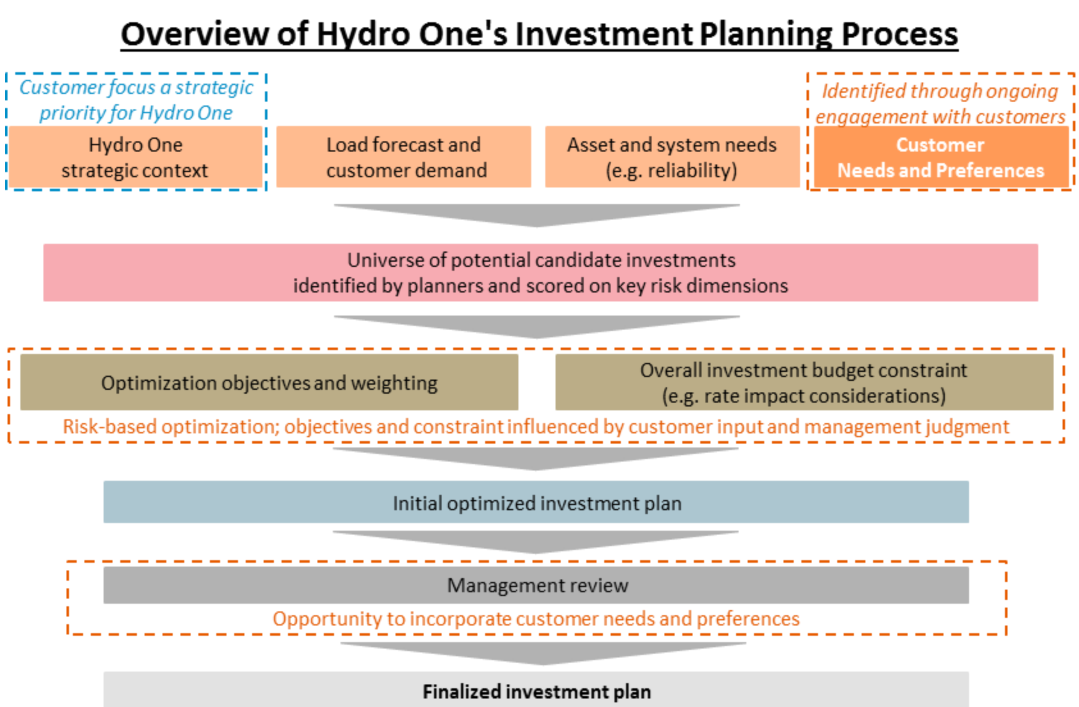
When submitted, each potential investment is scored according to a number of key criteria including the outcomes reviewed with you in this survey.

The total pool of candidate investments is then prioritized using an optimization tool that evaluates the scores assigned to all investments and compiled in to an initial investment plan.

This initial plan is then reviewed by management who evaluate the outcome of the optimization tool to ensure the plan is appropriately addressing the needs of Hydro One's assets along with the needs and preferences identified by Hydro One's customers, including the impact on rates.

Any concerns identified by this review are then incorporated in to the final plan that is approved for execution. The investment planning process is illustrated below.

Hydro One's has invested $4.3B in capital for its transmission system over the past 5 years (2012-2016).



How Hydro One's Rates Are Set

Hydro One is a rate-regulated company. Hydro One must apply to the Ontario Energy Board (OEB) for approval of its revenue requirement and the rates it charges customers. Rates are designed such that Hydro One recovers the costs allowed by the OEB and also allow Hydro One to earn a formula-based annual rate of return on its equity invested in the regulated businesses. This allowed Return on Equity is set by the OEB by applying a specified equity risk premium to forecasted interest rates on long-term bonds.

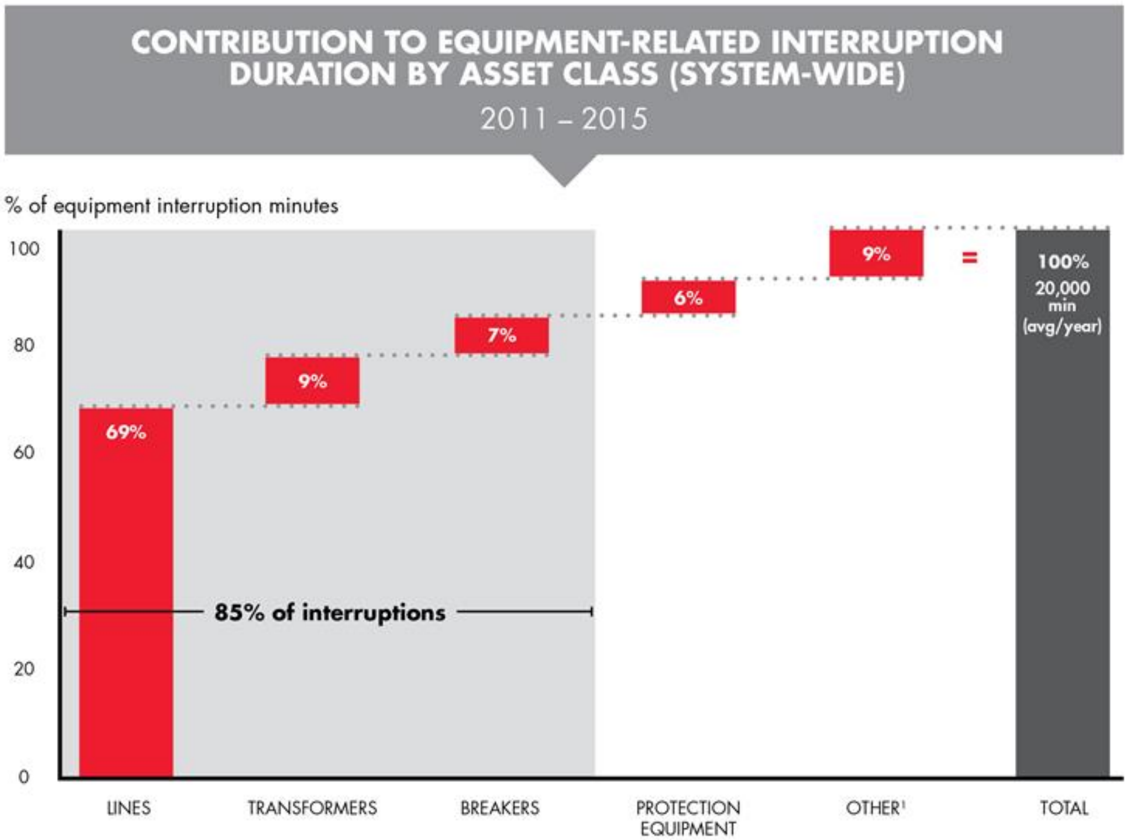
The table below summarizes the OEB-approved Transmission revenue requirement and the associated change over the prior year's revenue requirement for the 2012-2016 period.

	2012	2013	2014	2015	2016	5 Year Average
Revenue Requirement	1,418.4	1,437.7	1,535.3	1,527.2	1,567.6	
Change YoY (%)	5.1%	1.3%	6.4%	-0.5%	2.6%	3.0%

Hydro One System's Asset Health

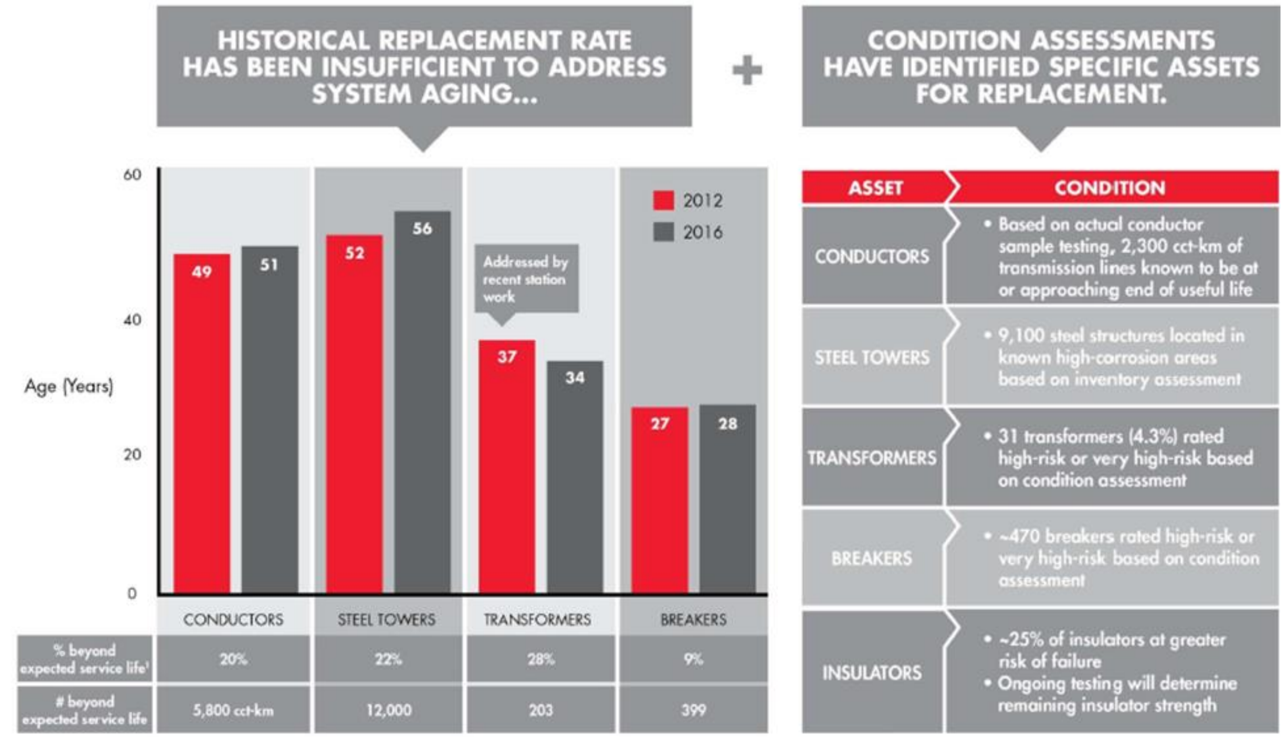
As the system ages, so do critical assets, resulting in equipment failures and sometimes in power interruptions.

While transmission lines are the primary cause of equipment-related interruptions, transmission lines, transformers and breakers combined accounted for 85% of system interruptions between 2011 and 2015.



1. Other includes switches, instrument transformers, surge arrestors, system auxiliaries

As of 2016, at least one-in-five conductors (19%), steel towers (22%) and transformers (28%) are beyond their expected service life. This translates into 5,800 circuit-kilometers of lines, 12,000 steel towers and 203 transformers. Many of these assets are already planned for replacement, but other assets continue to age beyond their expected service life.



1. The average time in years that an asset can be expected to operate under normal system conditions.

Asset Demographics

Hydro One only replaces assets that are in poor condition. The condition is determined through inspection and testing. However, a driving factor of equipment condition is age and equipment is more likely to require replacement as it ages.

The figures below show the number of units of each key asset (transformers, breakers and conductors) that has been put in to service since the 1930s. The figures show that a large number of key assets were put in to service between the mid-60s through to the mid-70s. In the next 10 years, those assets, representing a significant portion of Hydro One's total assets, will likely require replacement.

A sizable portion of each critical asset class is operating beyond expected service life.

Specifically, 28% of transformers, 9% of breakers and 19% of conductors are currently operating beyond their normal expected service lives.

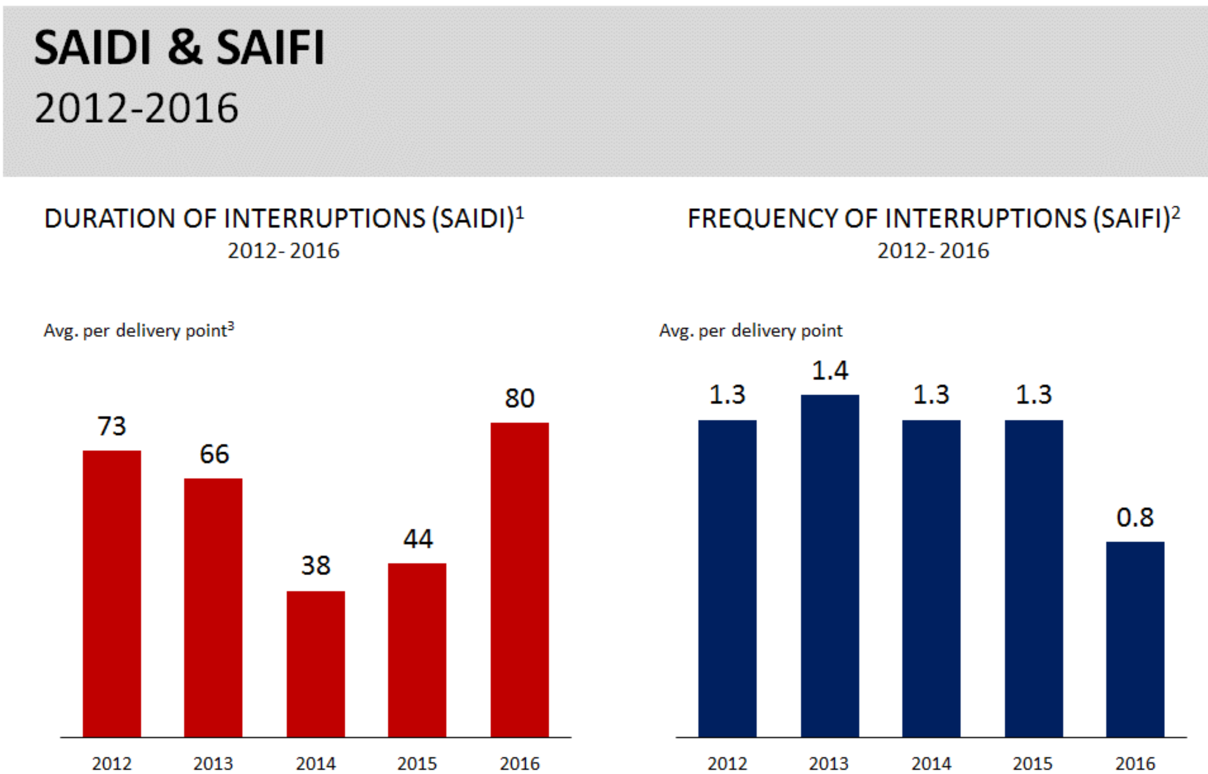
Reliability

Service reliability is typically measured by the average number, or frequency, of interruptions (SAIFI) and by the average duration of interruptions (SAIFI). The figures below show Hydro One's reliability performance from 2012-2016. The number of interruptions (SAIDI) was relatively stable over that period, with an improvement in 2016. The average length of interruptions showed some variability over the last five years but appears to be trending upwards in recent years.

When it comes to Transmission reliability, Hydro One has performed well compared to its Canadian peers.



Note: Includes both sustained and momentary interruptions. Excludes planned interruptions and interruptions due to customer activity. Excludes 2013 GTA flood (extreme Force Majeure event - a natural consequence of external forces that are beyond reasonable control).
1. System Average Interruption Duration Index
2. System Average Interruption Frequency Index
3. Interface between the Hydro One transmission system and its load customers. Delivery points consist of: (a) all Hydro One owned step-down transformer stations' low-voltage buses, and (b) stations owned by end-use transmission customers, including LDCs and other transmitters operating at 115kV or higher.

Reliability: Issues Driving Performance

A significant driver of the reliability performance experienced by a customer is whether or not that customer is connected to a circuit with redundancy. Customers on a circuit without redundancy experience 10x the average length of outages as those that are connected to delivery point with redundancy. About 30% of Hydro One's delivery points do not have redundancy.

Aside from redundancy, equipment performance is the largest controllable factor when it comes to system reliability, contributing 42% of system *interruption*[1] minutes. Asset continue to age (e.g., 19% of conductors are now beyond *expected service life*[2] of 70 years) increasing the number of equipment related reliability issues.

Condition assessments have identified critical replacement needs, for example:

• 2,300 cct-km of conductors identified for priority replacement due to being at or near end of useful life[3].

• 9,100 steel towers at heightened failure risk due to depletion of their corrosion protection layer.

Hydro One continues to take action to mitigate reliability risk by:

• Managing equipment performance through robust, condition-based asset replacement programs.

• Reducing customer exposure to single-supply through improved planning and work processes.

1. Outages on the transmission system that interrupt the supply of energy to transmission customers.
2. The average time in years that an asset can be expected to operate under normal system conditions.
3. As asset-specific determination based on an asset's condition, criticality, performance, demographics, utilization and economics.

Reliability Risk Model

System reliability is often measured by the frequency and duration of power interruptions. These are historical measures or lagging indicators of performance because they are indicators of past asset investment decisions. While we can measure the historical contribution of equipment failures to system reliability, not every equipment failure leads to an interruption due to the redundancy of Hydro One's system. As a result, Hydro One cannot predict the impact of investments in equipment on SAIFI and SAIDI for the parts of its system that benefit from redundancy.

Reliability risk is a forward looking or leading indicator of system reliability performance. It is calculated using a model which forecasts the risk or probability of asset failure (or needed replacement), based on the historical relationship between asset age and retirement.

It is an outcome measure used to indicate the potential improvement or decline in system reliability as the result of an investment plan. This measure also serves as a directional indicator to inform the appropriate level of pacing of sustainment investments to avoid future decline in reliability. The reliability model is not used to identify specific asset needs and investments. Hydro One chooses the assets it replaces based on detailed assessments of their actual condition.

Delaying capital spending will, in time, result in more and more equipment outages. While redundancy ensures these outages do not immediately lead to customer interruptions, the outages will leave multi-circuit customers at risk of experiencing single-circuit reliability. Reliability risk helps to capture the expected risk customers face under these conditions.

Primary Causes Contributing to SAIDI

Configuration: Interruptions due to system configuration issues where there may have been no direct transmission system equipment outage involved. This includes, loss of system issues originating in adjoining systems including other utilities and customers.

Environment: Interruptions due to adverse environment condition that existed at the time of the outage including pollution, humidity, flooding, and smoke.

Equipment: Interruptions due to defective equipment that has suffered deterioration, faulty design or materials, or lack of maintenance.

Foreign: Interruptions caused by incursions by articles or events that would not normally part of the electricity system. These include such things as vandalism, animals, solar induction, and aircraft.

Human: Interruptions caused by human error including incorrect use of equipment, incorrect documentation or labelling leading to misoperation, faulty settings, damage caused by employees or contractors during a work activity.

Weather: Interruptions caused by adverse weather conditions such as lightning, freezing rain or hail, high winds, and extreme temperature.

Outcome Definitions

Customer Service

Enhancements to the transmission customer experience such as outage planning and operational communications, timely estimates and project execution for transmission connected customers.

Environmental Stewardship

Identifying potential risks to the environment as a result of emissions from Hydro One's own operations, and investing in mitigation strategies to ensure compliance with all applicable environmental regulations consistent with the Government of Ontario and the Government of Canada.

Outage Restoration

Provisions to ensure timely and efficient response to failures, unplanned outages, or imminent risks to the transmission system to minimize customer interruption and prompt restoration to normal operating conditions.

Power Quality

Delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform. Assessing customer concerns and working together to implement mitigation plans to address and rectify power quality issues for transmission connected customers.

Productivity

Hydro One understands that customers expect it to look first for internal savings before asking customers to pay through increased rates. Implementation of new technologies and processes to enable operational efficiencies in the planning and execution of work programs aimed at reducing costs and more efficient use of resources.

Reliability

Maintaining the uninterrupted operation of the transmission system for all customers by sustaining the existing assets, replacing assets that are in poor condition and addressing transmission system performance outliers.

Safety

Eliminating and mitigating risk to public and employee safety in the operation of the transmission system.

Customer Outcomes: Performance

Reliability

Reliability performance is typically measured by the average number of outages experienced by its customers (SAIFI) and the average length of outages (SAIDI). Hydro One's SAIDI and SAIFI performance has been relatively steady of the 2012-2016 period, as shown in the Reliability section of this background material.

Safety

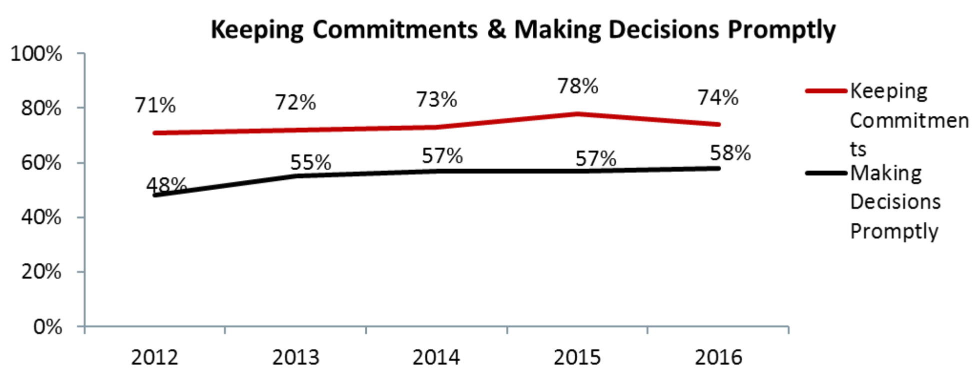
Public and employee safety are one of Hydro One's key strategic objectives. Hydro One's ultimate goal is strive towards zero safety-related incidents. The table below shows the number of serious work-related injuries/illnesses per 200,000 hours worked that have occurred from 2012-2016 along with the targets set by Hydro One. As shown in the table Hydro One has been outperforming its targets over the last five years.

Year	2012	2013	2014	2015	2016
Actual	2.3	2.5	1.8	1.7	1.1
Target	2.2	1.9	1.9	1.7	1.6

Customer Service

Every year, Hydro One conducts a survey of its large transmission customers. Among other things, Hydro One asks it's customers whether they feel Hydro One keeps its commitments to them and whether they feel Hydro One's staff makes decision promptly.

Results from 2012-2016 are shown below. The number of customers that believe Hydro One staff makes decisions promptly has increased by 10% over that period. The number of customers that believe Hydro One staff keeps its commitments has been consistent over that same period. Hydro One is committed to being more customer-focused and improving its customer service.



Detailed Scenario Summary

	Illustrative Scenarios			
	A: Limited investment	**B: Decrease in current level of investment**	**C: Maintain current level of investment**	**D: Increase beyond the current level of investment**
5 Year Capital Investment	$1.8 B	$4.3 B	$6.6 B	$7.4 B
Reliability Risk	Increase in risk ~30%	Increase in risk ~10%	Decrease in risk ~10%	Decrease in risk ~15%
Long-term Reliability Impact	↓	↓	↑	↑*
Average Percentage of Key Assets Beyond Expected Service Life by end of 2023 (21% in 2019)	29%	26%	19%	17%
Number of Key Assets With a High Probability of Failure by end 2023 †				
Transformers (12 in 2019)	14	12	9	9
Breakers (121 in 2019)	174	144	125	121
Conductors (329 circuit-km in 2019)	419 circuit-km	362 circuit-km	285 circuit-km	273 circuit-km
Impact on Future rates	Significantly higher future rate increases	Higher future rate increases	Level future rate increases.	Slightly lower future rate increases.
Average Annual Total Bill Impact – Distribution Connected Customer	0.09%	0.23%	0.35%	0.38%
Average Annual Total Bill Impact – Transmission Connected Customer	0.11%	0.27%	0.42%	0.46%
Average Annual Transmission Rate Increase	1.30%	3.30%	5.10%	5.60%

* Improvement in overall long term reliability and significant performance improvement for small number of customers connected to the worst performing circuits

† As predicted by the reliability risk model. Hydro One only replaces assets in end of life condition, as determined by detailed asset condition assessments.

NOTE: Transmission charges assumed to represent 8.3% of total bill for Transmission connected customers and 6.8% for Distribution Connected customers.

Glossary

Capital Investment: Money used by a business to purchase fixed assets, such as land, machinery, or buildings.

Circuit: An electrical connection involving metallic conductors that transmits electricity between 2 points.

Circuit Breaker: A switching device for that stops or allows the flow of electricity between electrical equipment.

Conductors: A metallic wire that conducts electricity.

Connection Capacity: Hydro One's ability to add new customers and/or additional load to the transmission system.

Customer Service: Enhancements to the transmission customer experience such as outage planning and operational communications, timely estimates and project execution for transmission connected customers.

Delivery Point: The point of supply where the energy from the system is transferred to customers. This point is generally taken as the interface between utility-owned equipment and the customer-owned equipment.

Expected Service Life: The average time in years that an asset can be expected to operate under normal system conditions.

End of Life: the likelihood of failure, or loss of an asset's ability to provide the intended functionality, wherein the failure or loss of functionality would cause unacceptable consequences.

Frequency Deviations: Fluctuations beyond the normal operating frequency range.

High-Voltage Transmission Network: Interconnected circuits that operate at 115kV and higher voltage.

Interruption: A stop in the flow of electricity to a customer.

Key Assets: Major types of transmission assets defined as transformers, circuit breakers and conductors.

Long-Term Reliability: Reliability performance beyond the 5 year rate filing period.

Multi-Circuit Systems: Systems where power delivery points are supplied by more than one circuit.

Outage: Unavailability of electrical equipment due to disturbances, equipment maintenance, or equipment malfunction. Outages do not necessarily lead to interruptions for customers if there are backup or redundant facilities to maintain electrical supply.

Outage Restoration: Provisions to ensure timely and efficient response to failures, unplanned outages, or imminent risks to the transmission system to minimize customer interruption and prompt restoration to normal operating conditions.

Outliers: Individual assets or sets of assets whose performance is significantly different than the average performance of the system as a whole.

Power Quality: Delivering electricity within established voltage and frequency tolerances with a smooth voltage curve waveform. Assessing customer concerns and implementing mitigation plans to address and rectify power quality issues for transmission connected customers.

Productivity: Implementation of new technologies and processes to enable operational efficiencies in the planning and execution of work programs aimed at reducing costs and enabling more efficient use of resources.

Redundancy: The inclusion of duplicate components to the system so that delivery points have multiple simultaneous connections. The purpose is to reduce the possibility of interruption in case of component failure.

Reliability: Maintaining the uninterrupted operation of the transmission system for all customers by sustaining the existing assets, replacing assets that are in poor condition and addressing transmission system performance outliers.

Reliability Risk: An index that provides leading directional indication of overall system reliability performance based on probabilistic risk of asset failures.

Safety: Eliminating and mitigating risk to public and employee safety in the operation of the transmission system.

Short-Term Reliability: Reliability performance within the 5 year rate filing period.

Single Circuit Systems: Delivery points that rely upon one circuit for the delivery of power. If that circuit fails then power is interrupted.

Sustainment Capital: Capital Investments made in order to maintain the current expected level of functionality and capability of system.

System Average Interruption Duration Index (SAIDI): The average outage duration for each customer served.

Transformer: An electric power equipment that changes the electricity voltage level. In Ontario, the transmission level voltage are typically transformed from 500kV to 230kV and 230kV to 115kV. To supply customers, 115kV and 230kV transmission voltages are transformed to distribution level voltages.

Transmission Stations: An electrical facility that connects a number or transmission circuits and transformers and performs a “hub” function for the flow of electricity across a region.

Transmission System Performance Outliers: Individual assets or sets of assets whose performance is significantly different than the average performance of the system as a whole.

Voltage Waveform: The shape of the 60Hz voltage curve observed at the supply point.

Stakeholder Session

Transmission Customer Engagement

In preparation for Hydro One's 2019-2023 Tx Application

March 29, 2017

Purpose of Stakeholder Session

Obtain input from Stakeholders as to the form and substance of Hydro One's upcoming Transmission Customer Engagement Process.

Why Customer Engagement

- Consistent with Hydro One's evolution to becoming a commercial entity: focus on customers, greater accountability for performance outcomes, and driving continuous improvements in efficiency and productivity company-wide.

- Inform the development of Hydro One's Transmission System Plan and Transmission Rates Application for 2019-2023 (to be filed Spring 2018)

- Meet or exceed the OEB's expectations pursuant to the Renewed Regulatory Framework (RRF) and meet the filing requirements relating to customer engagement from Chapters 2 and 5 of the Filing Requirements and the Handbook to Utility Rate Applications.

OEB Customer Engagement Filing Requirements

- Chapters 2 and Chapter 5 of the Filing Requirements and the Handbook require:
  - Engagement process be **designed** to identify customer needs and preferences;
  - Customer needs and preferences be **identified** as a result of the engagement process; and
  - Outcomes of the engagement process **inform** the asset planning process; specifically, how customer needs and preferences are **integrated** into an investment plan and how the **trade-off** between outcomes and costs has been made.

Customer Engagement – Hydro One Experience

- Hydro One has conducted two full customer engagement processes to support its
  - 2017 - 2018 Transmission Revenue Requirement Application, and
  - 2018 - 2022 Custom Incentive Distribution Rates Application.
- In both applications, the customer engagement process informed Hydro One's judgment on where customer needs and preferences, customer rates, and asset needs are aligned in the respective TSP and DSP.

Transmission: What We Heard

- Timing: engagement did not take place early enough to have impacted business decisions;
- Participation Rates were low
- Did not engage with all customers who will be impacted by the proposed rate increases (i.e., end-users of LDCs);
- Reliability Performance: top quartile status not adequately communicated;
- Information confusion;
- Investment Scenarios: not enough options, no zero rate option;
- Outcomes: reliability risk model not accepted as sole outcome measure; risks exaggerated;
- First Nations and Métis not represented; and
- Purpose of Engagement: customers may not have understood what was being asked of them.

Your Thoughts and Input

- Number of scenarios and how scenarios should be differentiated: rate impact, outcomes valued by customers, or size of 5-year capital envelope;
- Identification of outcome measures;
- How to capture needs and preferences of Distribution-connected end-use customers (i.e. end users of transmission services who are not transmission-connected customers per the Transmission System Code);
- How to capture needs and preferences of First Nations and Métis customers;
- Minimizing information Confusion;
- Timing;
- Participation Rates; and
- Clarity of Purpose
- What other issues should we be aware of?

Recall the “scenarios” we previously used?

hydro one

OVERVIEW OF THREE POTENTIAL SCENARIOS

hydro one

2016 – 2020 Transmission System Net CapEx ($B)

		SCENARIO 1	SCENARIO 2	SCENARIO 3
Capital Spend	Sustainment ($B)	3.5	4.0	4.6
	Development ($B)	1.1	1.1	1.1
	Other ($B)	0.5	0.5	0.5
Expected Outcomes	Frequency and duration of interruptions	▲ Expected increase in line-related interruptions	▶ Some increase in lines risk offset by limiting unplanned outages and improved station performance	▼ Reduce risk from lines and continue to limit exposure to unplanned outages
	Reliability risk[1]	▲ Risk is expected to increase	▶ Current risk expected to remain essentially unchanged	▼ Risk is expected to decrease
Rates	Transmission rate impact (Compound Annual Growth Rate for 2017 – 2020)[2]	▲ ~5.8%	▲ ~6.3%	▲ ~6.8%

1. Reliability risk is a probabilistic calculation based on asset demographics and the historical relationship between its age and its failure or replacement.
2. Excludes impacts of potential changes in load forecast and any potential change to operations and maintenance spending.

Scenarios

Issue: Number of scenarios and how scenarios are differentiated.

Straw Dog: Four scenarios – Differentiated by size of Rate Increase (%) and resultant Outcomes

Scenario #1: Investment plan resulting in zero percent rate increase

Scenario #2:
Scenario #3:
Moderate rate increases with different investment plans and outcomes

Scenario #4: Investment plan resulting in a higher rate increase.

As in previous engagements – the scenarios are intended to represent a range of alternatives, and are not suggested as discrete choices

Scenario Issues

- Is it appropriate to differentiate based on rate increase or should other differentiators be used?
- Are 4 scenarios the right number to go with?
- Is a 0% rate increase an appropriate starting point for scenarios?

Outcome Measures

Issue: Which outcome measures are appropriate?

Options: Reliability Risk
T-SAIDI
T-SAIFI
Outlier Performance
Safety
Environmental Impact

- Other outcome measures?
- How many measures should be discussed?

Customers Engaged

Issue: How to capture needs and preferences of Distribution-connected end-use customers (i.e. not -transmission-connected)

Straw Dog:

Since LDCs serve these customers, rely on LDCs to represent their customers' needs and preferences to the Transmitter, based on

- their own customer engagement work (including Hydro as well as other LDCs)
- Results of LDC conducted surveys

Alternatives:

- Survey LDC customers directly (potential confusion?)
- Review LDC customer engagement evidence filed with the OEB
- Separately survey LDCs as representatives of their customers

Other approaches?

First Nations and Métis

Issue: First Nations and Métis Engagement

Straw Dog: Rely on the customer engagement work of Hydro One Distribution and other LDCs

» Results of LDC conducted surveys
» LDC customer engagement evidence filed with the OEB
» Survey of LDCs as customer representatives, focusing on First Nations and Metis customers specifically

Alternative: Engage directly with First Nations and Métis

Other approaches?

Information Confusion

Issue: Information Confusion

Specific information to clarify with customers:

- – End of Life
- – Expected Service Life
- – Role of age vs condition
- – Reliability
- – Reliability Risk
- – Service Interruption vs Outage
- – Hydro One's historical reliability performance

Other Issues

Timing: Hydro One plans to conduct its Tx Customer Engagement in April- May 2017, and complete the engagement by the end of May 2017, to allow it to commence development of the investment plan

Participation Rates:

Recognizing customers' time constraints, instead of 3 discrete waves (one-on-one meetings, workshops, and an on-line survey), offer customers a choice of channels to provide their needs and preferences

Purpose: Spend more time explaining the purpose of the engagement, its role in the process, the need to balance competing priorities, and any planning constraints facing Hydro One in preparing an investment plan

What other issues should we be mindful of?

What other input or advice can you offer?

Hydro One Networks Inc.
2019-2023 Transmission Rate Application

Transmission Customer Engagement Stakeholder Session

Summary Report

Delta Chelsea Hotel
Toronto, Ontario

March 29, 2017

Session Overview

The session began with an introduction provided by Jody McEachran, Regulatory Affairs, Hydro One. Mr. McEachran highlighted that the purpose of the session is to engage stakeholders in an interactive discussion about the upcoming Transmission Customer Engagement Process being planned in preparation for the 2019-2013 Transmission Rate Application.

An overview of the agenda was then provided by the session facilitator Tracey Ehl, Ehl Harrison Consulting Inc. All stakeholders introduced themselves, including their names, organization and position. Introductions were followed by a presentation by Oded Hubert, Vice President, Regulatory Affairs, Hydro One Networks.

Participants were encouraged to ask questions and provide feedback throughout the delivery of Mr. Hubert's presentation. This report is a synthesis of the discussion from the session, organized by key question. In each section, stakeholder comments are numbered, with the responses, by either participants or staff, directly following. Comments and questions received after the session are not reflected in this report.

A list of participants can be found in Appendix A.

Stakeholder Discussions

A. **Transmission Customer Engagement** (Oded Hubert)

Summary: Mr. Hubert highlighted the importance of the customer engagement component of the upcoming Transmission Rate Application and emphasized that the session was aimed at gathering the thoughts and insights of stakeholders on the form and substance of the engagement activities. Mr. Hubert recapped that Hydro One has conducted two full customer engagement processes to support recent applications. He reviewed key process-related challenges from these two processes and sought input and discussion about approaches to addressing them. Key topics included scenarios, outcome measures, engagement with distribution-connected end-use customers, First Nation and Métis engagement, information confusion, and other issues.

There were a number of key discussion themes that arose from the conversation, as follows.

- *It is important to identify the purpose of the engagement (build plan or tweak plan) and then identify the approach.*
- *Stakeholders felt strongly that the OEB's decision regarding the current (2017-2018 Transmission) application that is before the Board would be important context to this engagement process, and proceeding prior to the decision is not ideal.*
- *The scenarios may not be the most effective starting point for the engagement, because this quickly narrows stakeholder focus, away from system considerations of the application.*
- *The schedule, as presented, is very aggressive. There may be some benefit to continuing the engagement process while the application preparation is ongoing.*
- *Additional (local/granular) information and context (including about past spending and performance trends) should be provided to customers in order to engage in more meaningful feedback/dialogue. The story has to be linked to customer experience outcomes.*

- *There would be great benefit for this and future applications if focus was given to educating/explaining key terms and business practices.*
- *Any engagement approach has to be balanced with the potential for consultation fatigue.*
- *With respect to understanding the needs and preferences of LDC customers, while it is possible to learn from engagement done by LDCs (through data mining), it is still important that Hydro One conduct an engagement processes to hear from end users.*
- *Industry best practices are not readily available. To overcome this, one approach may be to seek the input of a small sample of customers about the engagement process. This may provide valuable input to how process design could support their engagement and more effectively meet Hydro One's application needs.*

General discussion:

1. Is proposed Rate Application expected to be aligned with the Transmission System Plan that was filed with the 2017-2018 Application?
   - Yes.

2. What was the participation rate of LDCs in the last Tx Engagement? The reason for this question is to discern whether the LDCs represent the interests of their customers.
   - Participation rates are not available at this time.

3. Customers need to understand how reliability is affected by Transmission and Distribution. Where (in which system) should the investment be?
   - This was not explored in the previous engagement efforts.

4. Slide 6, what we heard, should include mention of the feedback related to the difference between multi circuit and single circuit systems.

5. Hydro One should wait for the OEB decision before talking to customers again.
   - This will assist in defining parameters and scenario building.
   - Results from Board decision will provide direction that may point you in a different direction.

6. "I'm not sure how you can go to your customers until the decision is known."

7. It is premature to start working on scenarios at this point. Hydro One should focus on designing the process and this will inform how the scenarios are developed.

8. Hydro One should also seek feedback on the incentive regime.

9. Providing customers with an understanding the historic investment strategy and spending will help to inform a good discussion about the future.
   - An educational component will be very important.

How many scenarios should be utilized? Is this the right approach?

1. While scenarios are important, Hydro One may want to consider a more organic process.

2. I have an issue with scenarios. Customers pick the scenario that will benefit them.

- (Hydro One staff) When we talk to customers, they all bring their own issues and preferences which are focused on the individual customer.
- Responses are diverse among customers.
- Scenarios outcomes should be refined by customer.

3. During the previous engagement, was data presented on different types of circuits?
    - (Hydro One staff) Data was presented at a network level. Greater granularity may be of assistance. We have 10 geographic areas across the province. This will provide information relevant to specific groups. This information base could help inform the engagement process

4. Momentary interruptions are a big issue for some industrial customers.
    - (Hydro One staff) Power quality is a 'fuzzy' issue but we had great feedback from our customers on this. As a result, we are focusing more on this in our business plan.

5. People (customers) want to better understand what investment is being done on 'my network' on 'my supply'.

6. Scenarios should show customers what the outcome is for different levels of spending and for spending the same amount (i.e. the middle scenarios). For the middle scenarios, there are different outcomes depending on where the spending is done. Outcomes need to be refined to demonstrate impact and delineated by region.

7. It is not clear to me how Hydro One incorporates a five-year plan (into two-year scenario) and is able to incorporate the outliers? My sense is that there should be more latitude to respond to outliers. Scenarios are 'grab-bags' with a certain amount of latitude for the opportunity to discuss the trade-offs

8. Customers need to understand the base scenarios (and performance trends over time). Under Scenario 1, customers need to see why a continued level of spending is not adequate given past performance. Why is a further increase needed? Under Scenarios 2 and 3, understanding performance trends historically and the impact moving forward with the spending is important for customers to understand. Consider what a rate reduction scenario (and the associated performance trends) looks like.

9. More clarity on outcomes is needed. Information should be provided about what is needed for a local area vs. system wide needs.
    - Take it to a level that we can see reliability risk.
    - Scenarios 2 and 3 will quickly become the focus.

10. The way that the issue is framed will change the feedback/outcome from stakeholders.
    - Reliability risk is not well understood.

11. Hydro One should start with consideration of who the customers are and what are the outputs that are important to them. This should inform the design of a survey that is most appropriate for them.

12. It is important to start with scenario 1 and to include explanation of the details that are contained within it, such as whether it is based on last five year system wide performance or whether it is disaggregated.

  - What are you going to project for end of life assets? This is an important part of the baseline.
  - More clarity is needed about where we are starting from.

13. There is concern about providing customer with end of life metrics, which can be misleading or misunderstood.

14. Are you still continuing with reliability risk model?
    - Yes, Hydro One is continuing to develop the tool, along with exploring its role. It was developed as an outcome measure.

15. Hydro One should still be using a reliability risk model.

16. What I heard about the last engagement process was that there is a need to understand performance in the past, what spending has been done, and why you need the extra funding. This data/information will help get support.
    - Why don't you demonstrate to customers what a reduction in rate would result in? Customers could then understand outcome.

What outcome measures are appropriate?

1. How can we differentiate reliability? How can we better understand the customer perspective?
    - During consultations, it was suggested more granular information was preferred.
    - Aren't there meetings throughout the year with large customers to discuss the key issues? Do customers want to get additional details?
    - (Hydro One staff) When meetings happen on a monthly basis or ad hoc, the focus of meetings is often about specific events at the customer level, with less focus (if any) at the system level. Customers appreciate understanding the network but then close in on their specific context.

2. Outcome measures that speak to equipment performance, number of customer interruptions, number of customer interruption hours are important and understandable.
    - T-SAIDI and T-SAIFI are not necessarily the most accessible measures to understand in a meaningful way.

3. There were outcome measures discussed (at hearing) that are worth considering, including: Power quality; Number of customer interruption hours/year; Equipment unavailability, failures; Outage versus interruption.

4. The measure should be T-SAIDI and T-SAIFI, but explained in a different way.

5. With respect to geography, what do you do with this information? Will it be used to direct funding? Data on reliability in each geographic area would be very good data to have.
    - (Hydro One Staff) It is a good idea to provide detailed, localized data.

6. Equipment unavailability is an important metric to convey information about equipment failure, how long it is unavailable for and why.

7. When I think of (engagement) slides from last time, slides on T-SAIDI and T-SAIFI showed an average over the last five years. It would have been interesting for customers to see the historic trends, along with looking at five years into the future. This is how you can build up the story for the scenarios.

8. Concern was expressed about showing percentage of outages. There should be an absolute number.

9. If the reliability risk model is not being used to make decisions, it is not that valuable to customers.
   - (Hydro One staff) Hydro One still views Reliability Risk as a meaningful outcome metric.

10. What are the metrics that Hydro One is watching when developing programs? These should be the ones that are also the focus of customer engagement.

11. Hydro One should start by looking at the experience with its own LDC and share this information.

12. It would be very helpful to ask customers to identify meaningful metrics to them. They will ultimately want to understand what they will experience.

How can Hydro One capture needs and preferences of Distribution-connected end-use customers?

1. First, the purpose has to be well understood. Is it to drive the plan development, or to tweak it after the plan has been developed? (Hydro One staff explained that it is the former.) Engage customers where there is material consideration.

2. Concern was expressed about LDCs representing their end-use customers in this type of engagement scenario.
   - They have their own incentives, so care has to be exercised.
   - Mining data from LDCs is challenging, and may not yield useful information for the purpose.
   - Surveying customers directly may be a better approach, however it may lead to confusion.

3. There is a large information gap related to Hydro One business terms and concepts. For example, what is a major event?
   - It is important to get higher level information from customers.
   - You do need to talk to end users but don’t ask how money should be spent.
   - Need to think about what we want to know from end users.

4. If you talk to customers about reliability and rates, input will be contextualized by local inputs/outcomes. This could assist to get sense of the level of satisfaction and then this can inform planning.

5. The customer data collection by LDCs has been fairly rudimentary and self-serving.
   - It is important to understand what the LDCs are saying and their perceptions of inputs.
   - As we move forward, discussion should be more organic.

6. Depending on who you talk to you, there will be different perspectives.

7. What do you want to do with the customer data? If it is to drive the plan we have an issue because we are not talking to the right people. If it is to tweak then maybe it is not as big of an issue
    - Not sure where the Board is going with engagement, as they seem to want engagement but it doesn't seem to impact decisions.
    - (Hydro One staff) For clarification, the purpose of engagement is to inform the plan prior to its development.
8. What is the different between informing and tweaking
    - (Hydro One staff) "Tweaking" is presenting the plan to customers and gathering feedback. Informing is to get input into the development of the Plan

How can Hydro One effectively engage First Nation and Métis?

1. Why does Hydro One not use process defined in the 2007/2008 hearing? That was a robust process and should be utilized again.
    - (Hydro One staff) Hydro One did engage with First Nation and Metis at that time. That was a very large development plan for the entire province with impact on both t on and off-reserve land, but now we are in a sustainment' approach, so a different engagement approach was taken.

2. What do you think would be different in this customer group?
    - (Hydro One staff) Issues are wide ranging. Reliability is important, as are land rights, arrears, affordability, the proposed First Nation rate, past grievances, and past issues with Hydro One.
    - Other than these issues, what would inform a transmission plan in particular for this customer group?
    - (Hydro One staff) Hydro One would need to be clear on what the scope is of a Transmission-focused First Nations and Metis engagement.
    - Certain types of spending already involve engagement with these communities (i.e. Section 92).
    - (Hydro One staff) If we included First Nations in the Customer Engagement, this would not be the only forum, but we would be adding another level of discussion with First Nations.
    - How are First Nations and Métis engaged in regional planning? The IESO has set up local advisory committees for regional planning.
    -
3. This customer group should be engaged differently, through a lens of developing economic and social opportunity through the power system.

4. Best practices have been previously shared at a hearing and should be implemented here as well.

How can information confusion be addressed?

1. There needs to be an information/educational component to this engagement process, if the discussion is to be meaningful. For example, people don't understand the difference between end of life and expected service life.

2. The difference between service interruption and outage is confusing. Hydro One may not even need to speak about outages. Customers are most interested in service interruptions.
   - (Hydro One staff) When we talked to transmission customers, they do seem to understand this difference, as they interact with Hydro One on both equipment outages and interruptions.

3. Whatever information you convey to tell the story should include outcomes. The story has to flow into the outcomes.
   - (Hydro One staff) We are planning on informing the customer engagement process with new data but not any new concepts, such as reliability risk, which was introduced in the last engagement process.

Timing

1. Participants emphasized the importance of waiting for the (Board) decision before starting this engagement process, as one will inform the other.

2. Has the engagement consultant already been chosen?
   - (Hydro One staff) A vendor has not been chosen. It is anticipated that the engagement will include a number of channels, giving choice to customers on how they can provide their input.

3. A market research approach is more appropriate than opinion polling for this process.

4. How does the information that is collected get blended together?
   - (Hydro One staff) This is a real challenge. Education/framing is a huge undertaking, requiring time spent with customers. How much time can we actually get people to spend with us?
   - (Hydro One staff) We will be thinking about how can we segment our customers and provide the information that they need so they can provide input to better inform our plan.

5. Won't the anticipated decision impact plan going forward?
   - (Hydro One staff) Definitely. Customer Engagement is to inform the plan but we will also be informed by the Board Decision. There is a risk both to engaging early and to waiting.

6. (Hydro One staff) Should we continue engagement process into plan development phase?
   - An iterative process would be great, as long as all of the information gathered is incorporated back into the plan. An end date will be needed in this regard. Consider June timing or after the changes from the Fair Hydro Plan.

Participation Rates

1. The consultant hired will be able to assist with identifying and achieving good participation rates.

Purpose

1. Whatever you do will be more meaningful if you are able to provide them more information.

2. How are you framing the purpose? Inform plan or define spending?
    - (Hydro One staff) This engagement will inform the development of the plan.

What other issues should we be mindful of? What other advice do you have?

1. Is it Hydro One's position that you have to do a five-year application?
    - (OEB staff) Yes, this is the minimum period for a Custom IR.

2. Does anyone in North America do Transmission Customer Engagement? Can we look at best practices?
    - Staff and participants were not aware of current best practices. It was indicated by a participant that a lot of research was carried out in the past prior to the break-up of Ontario Hydro.

3. Make sure the engagement is meaningful to Hydro One and to customers.

4. What future Stakeholder engagement activities do you anticipate for this Application?
    - (Hydro One staff) This is still in planning stages, but information will be sent to you once it is known.

5. Is there an opportunity for Hydro One to meet with a small number of large industrial customers, LDCs and explore what approach to engagement might be meaningful to them?
    - (Hydro One staff) Yes. Also, LDCs were included in the invitation to participate in today's discussion, but due to schedule conflicts, none were able to attend.

Session Wrap-up

All stakeholders were thanked for their participation. Additional questions and/or comments were invited following the session.

Appendix A: List of Participants

Andrew Blair – Power Workers' Union
Bill Harper – VECC
Bohdan Dumka – SEP
Cary Ferguson – Anwaatin Inc.
Chris Codd – OEB Staff
Frederick Belanger – HQEM
Hanna Smith – IESO
Harold Thiessen – OEB Staff
Julie Girvan - CCC
Marion Fraser - BOMA
Mark Rubenstien - SEC
Megan Lunh - IESO
Roger Higgin – Energy Probe
Shelley Grice – AMPCO
Vicki Power – SEP

Hydro One
CK Ng – (Planning) Hydro One Networks
Erin Henderson – (Regulatory Affairs) Hydro One Networks
Jeffrey Smith – (Planning) Hydro One Networks
Jody McEachran – (Regulatory Affairs) Hydro One Networks
Oded Hubert – (Regulatory Affairs) Hydro One Networks
Scott McLachlan – (Planning) Hydro One Networks
Spencer Gill – (Customer Service) Hydro One Networks
Steven Vetsis – (Regulatory Affairs) Hydro One Networks
Warren Lister – (Customer Service) Hydro One Networks

Tracey Ehl – Facilitator
Jodi Ball – Note taker

ATTACHMENT 4: RELIABILITY RISK SUMMARY

The reliability risk model was introduced by Hydro One in 2016 to provide a method for demonstrating the value of sustaining investments to customers and to provide a directional indicator to assess the effect of an investment portfolio on reliability.

It is a simplified method to communicate risk to customers and stakeholders. It is not used to identify specific asset needs or justify investments. Asset needs are anchored by asset condition assessments and investments are justified by asset needs and prioritized in accordance with Hydro One's investment planning approach described in TSP Section 2.1, Investment Planning Process.

In order to solicit impact from customers the reliability risk model was one of several measures used in the 2017 Customer Engagement Survey to quantify and communicate the outcomes associated with various investment scenarios. Customer input was a key factor that informed Hydro One's overall investment plan, which underpins this rate application. During customer engagement, there was no preferred investment plan. The risk prioritization investment planning methodology which was used to prioritize the investments underpinning the TSP[1] was under development and not available as an alternative communication tool. As such, the reliability risk model was the method used to communicate risk to customers.

In its Decision in Hydro One's last Transmission Rate Application (EB-2016-0160) the Ontario Energy Board ("OEB") found that the model needs further refinement and testing if it is to be used to convey to customers information about the value of capital investments in terms of system reliability. A third party assessment completed by Metsco

[1] Detailed in TSP Section 2.1.

Energy Solutions Inc. has led to a similar conclusion and recommendations as discussed in TSP Section 1.4, section 1.4.2.14.

Hydro One is aware of reliability forecasting models however comprehensive assessment and testing of these models are not complete. Hydro One has completed substantial work in developing and refining hazard functions of its assets as discussed in TSP Section 1.4 which form a good baseline for forecasting investment requirements. Hydro One will continue to explore and assess other reliability forecasting models to quantify the outcome of its investment plan in the future.

2018 Large Tx Customer Satisfaction

Understanding Dimensions of Satisfaction and Dissatisfaction

Hydro One
483 Bay Street
Toronto, ON M5G 2P5

hydro one

October 2018 :: Review Draft

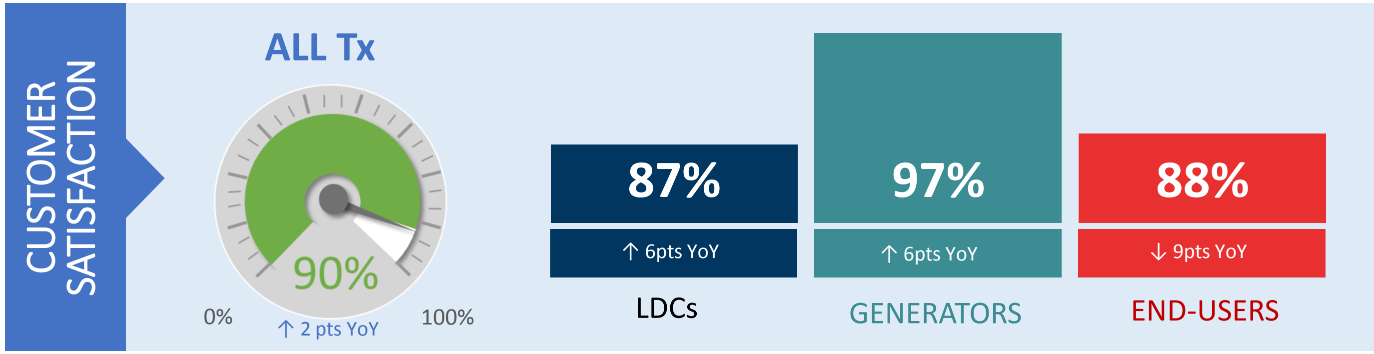
Summary: *2018 LTX Report*

1. **Hydro One's CSAT continues its upward trend and reaches an all-time high, with marginal improvement among Generators and LDCs effectively neutralizing a significant decrease among End-Users.**

2. ***Customer Service*** **is the dimension on which Hydro One has the highest levels of satisfaction.**

3. ***Product Quality & Reliability*** **shows room for improvement, particularly on customers' experience of unplanned outages.**

4. **Environmental controls were introduced in 2018 to gauge the impact of economic and political factors that are outside of Hydro One's influence.**



HIGHEST PERFORMING ATTRIBUTES

- Overall customer service (93%)
- Communication methods (93%)
- Service received from account executive (90%)
- Accessibility (87%)
- Understanding business needs (85%)

OPPORTUNITIES FOR IMPROVEMENT

- Duration of unplanned outages (48%)
- Number of unplanned outages (50%)
- Good value for money (58%)
- Communication during outages (62%)
- Time to restore power (66%)

Insights: Drivers of CSAT

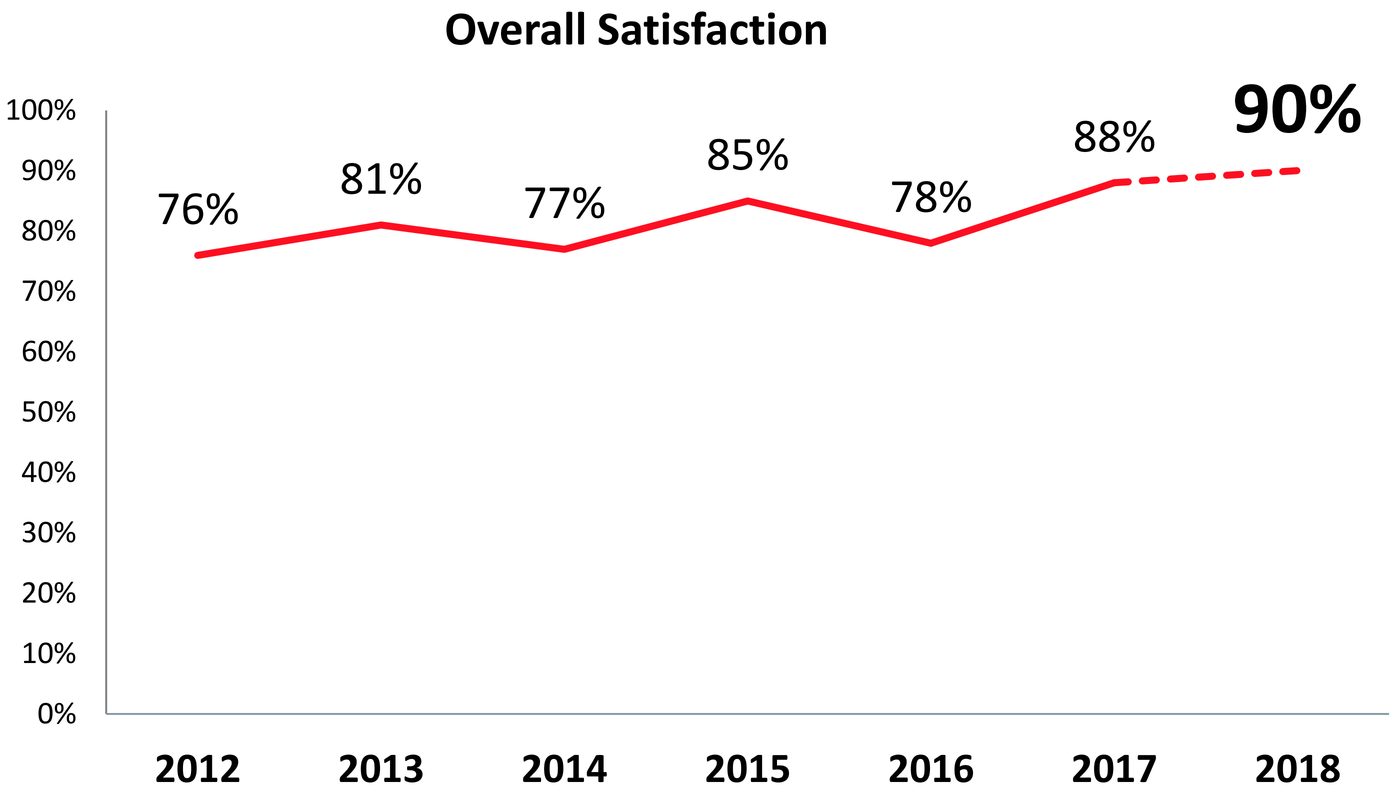
- *Customer Service* is the strongest driver of CSAT. This factor has an emphasis on communication:
  - communication methods
  - overall communication
  - service from Key Account Executive
- Being able to recall an unplanned outage has a negative effect on CSAT, which highlights the need to improve customers' experience of unplanned events.

Key Metrics of Satisfaction

Overall Satisfaction (All Tx): Overall satisfaction continues to trend upwards from 2016, landing at an all-time high of 90%

Q

C2. Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One?
[Asked of all respondents, n=112; valid responses n=112]



Key Insights

- Overall satisfaction continues to trend upwards from 2016, landing at an all-time high of 90%.
- Because there were no respondents who said “don’t know” to this question in 2017 and 2018, the results are reliably trackable. Therefore, we know that there has not been a significant change since 2017.

NOTE: Response "Don't know" (0% in 2017 & 2018) was excluded from this analysis. Statistically significant changes compared to the results from 2017 are indicated by ↑↓.

INNOVATIVE RESEARCH GROUP | hydro one

Overall Satisfaction (By Customer Type): Satisfaction among Generators and LDCs hits all-time high in 2018; End-Users down 9pts from 2017

Q

C2. Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One?

	2012	2013	2014	2015	2016	2017	2018
LDCs	80%	78%	74%	78%	64%	81%	87%
Gens	80%	89%	84%	81%	88%	91%	97%
EUs	66%	80%	76%	97%	88%	97%	88%

Key Insights

- Upwards trend of Generator satisfaction continues from 2015, surpassing both other customer groups in 2018.
- LDCs continue to increase from their record low in 2016, albeit less sharply than in 2017.
- End-Users down 9 points from 2017. Due to the small sample size (n=34), this is not a statistically significant change.
- The increase among LDCs and decrease among End-Users has closed the gap between those two groups.

LTX Customer Type	Total Population	Sample Size
LDCs	66	45
Generators	63	33
End-Users	72	34

NOTE: Response "Don't know" (0% in 2017 & 2018) was excluded from this analysis. Statistically significant changes compared to the results from 2017 are indicated by ↑↓. Differences between customer type that are statistically significant at a 95% confidence interval are indicated.

INNOVATIVE RESEARCH GROUP

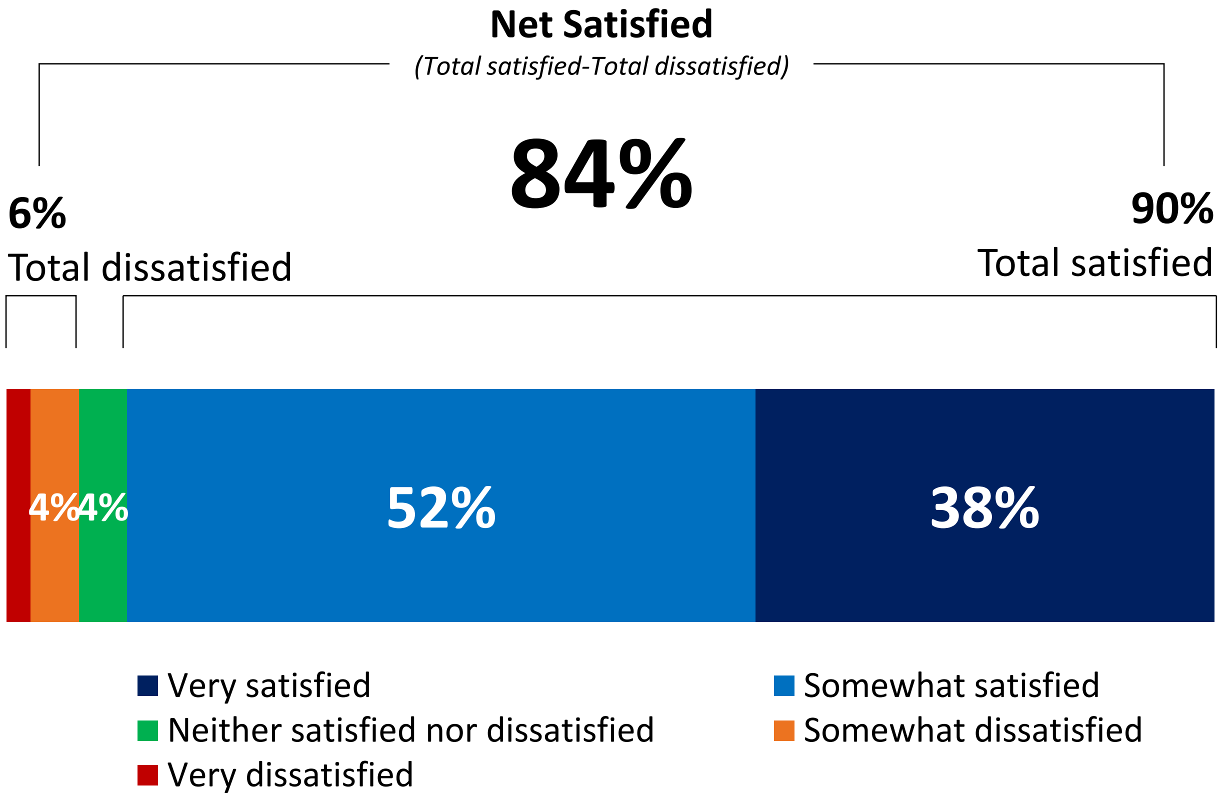
hydro one

A Closer Look:
Overall Customer Satisfaction

INNOVATIVE
RESEARCH GROUP

Overall Satisfaction: 9-in-10 (90%) LTX customers are satisfied with the service they receive from Hydro One

Q **C2.** Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One?
[Asked of all respondents, n=112]



Key Insights

- Overall satisfaction with Hydro One among LTX customers is verging on universal, but there is room for improvement on intensity. Currently, half (52%) are *somewhat* satisfied, while 38% are *very* satisfied.

NOTE: Response "Don't know" (0%) was included in this analysis

Overall Satisfaction (By Customer Type): Nearly 9-in-10 customers are satisfied across all customer groups; satisfaction highest among Generators

Q

C2. Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One?
[Asked of all respondents]

LDCs
[n=45; valid responses n=45]

Generators
[n=33; valid responses n=33]

End-Users
[n=34; valid responses n=34]

	Total Dissatisfied	Total Satisfied	Net Satisfaction
LDCs	11%	87%	+76%
Generators	-	97% > LDC	+97%
End-Users	6%	88%	+82%

■ Very satisfied ■ Somewhat satisfied
■ Neither satisfied nor dissatisfied ■ Somewhat dissatisfied
■ Very dissatisfied

Key Insights

- The level of intense satisfaction is virtually identical across all three customer segments.
- The higher proportion of somewhat satisfied and complete absence of dissatisfied Generators results in universal satisfaction among that customer group.
- The proportions are small, but there are some dissatisfied LDC (11%) and End-User (6%) customers.

INNOVATIVE RESEARCH GROUP | hydro one

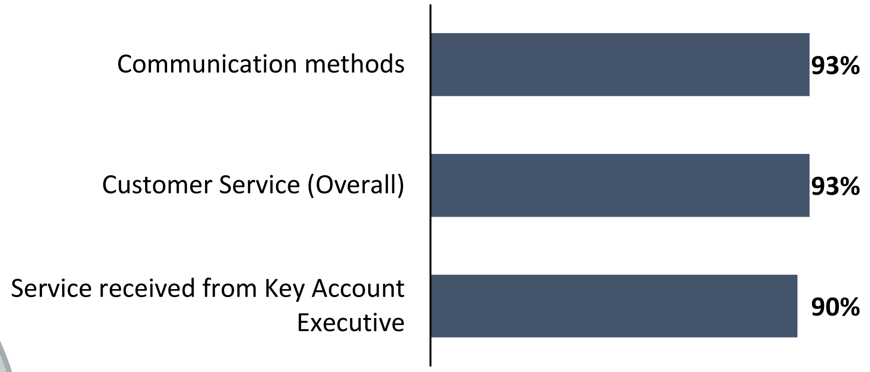
NOTE: Response "Don't know“ (0%) was included in this analysis
Differences between customer type that are statistically significant at a 95% confidence interval are indicated

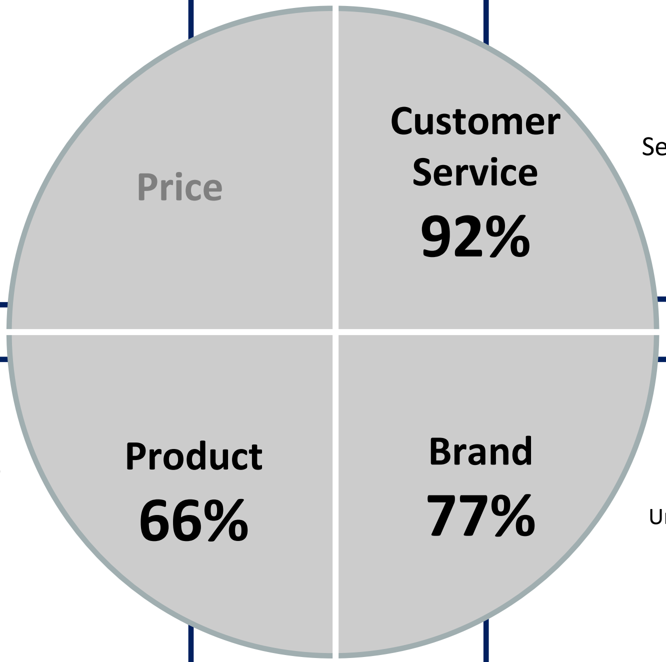
Survey Findings: Dimensions of Satisfaction (LTX – All Segments)

Price/Billing

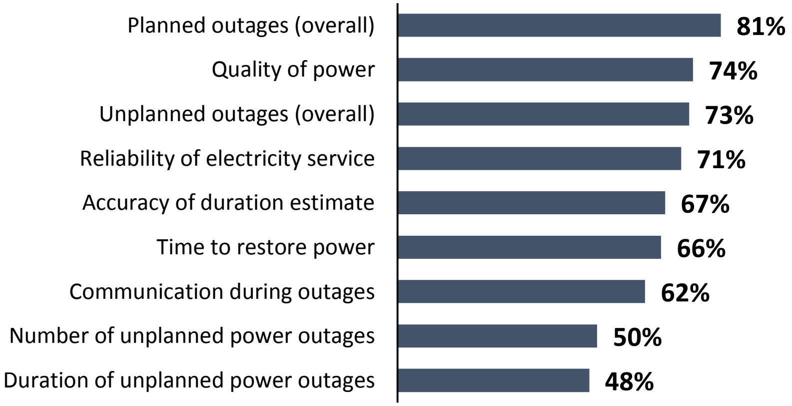
No price/billing questions pertaining to experience with Hydro One were asked of LTX customers

Customer Service





Product Quality/Reliability



Brand

NOTE: Percentages represent total satisfied (very and somewhat satisfied)
Response "Don't know" was included in this analysis.

Survey Findings: Dimensions of Satisfaction (LTX Segments)

Key Insights

- Generators are the most satisfied customer group across all dimensions.
- LDCs are the least satisfied, but just marginally.
- Customer service is the highest-scoring dimension across all LTX customer groups, whereas Product Quality/Reliability is the lowest,

Customer Service – 92%

LDCs	Generators	End-Users
2018	2018	2018
90%	96%	92%

Product Quality/Reliability = 66%

LDCs	Generators	End-Users
2018	2018	2018
62%	77%	64%

Brand – 77%

LDCs	Generators	End-Users
2018	2018	2018
73%	88%	73%

NOTE: Percentages represent total satisfied (very and somewhat satisfied).
No pricing questions were asked of LTX customers.
Response "Don't know" was included in this analysis.

Survey Findings: Dimensions of Dissatisfaction (LTX Segments)

Key Insights

- Dissatisfaction with customer service is nearly non-existent within these customer groups.
- Overall, Generators seem less dissatisfied than other customer groups, which aligns with their overall increase in overall customer satisfaction.
- 1-in-5 LDC and End-Users are dissatisfied with product quality and reliability in 2018. This is five times higher than dissatisfaction among Generators.

Customer Service – 1%

	LDCs	Generators	End-Users
2018	1%	1%	1%

Product Quality/Reliability – 15%

	LDCs	Generators	End-Users
2018	19%	4%	19%

Brand – 9%

	LDCs	Generators	End-Users
2018	10%	4%	11%

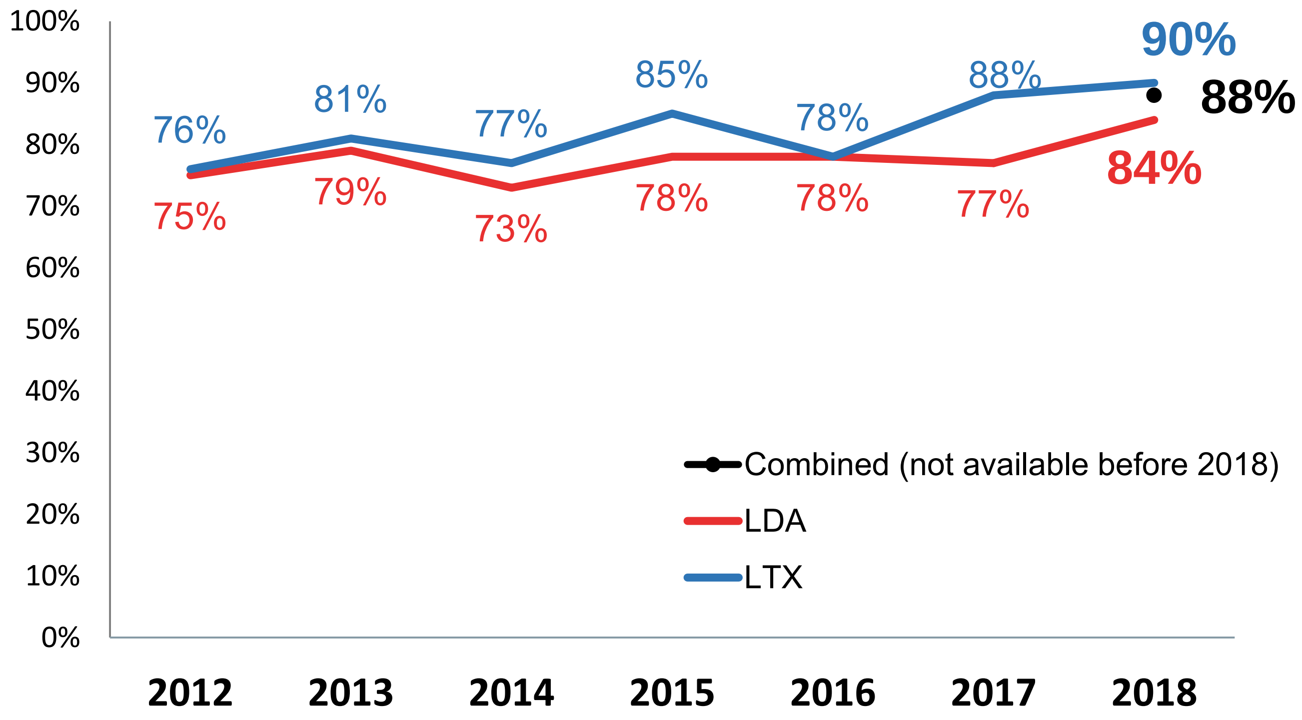
NOTE: Percentages represent total dissatisfied (very and somewhat dissatisfied) or total disagreement (strongly and somewhat disagree).
No Price/Billing dimension exists for LTX customers.
Response "Don't know" was included in this analysis.

Combined LTX and LDA Results

Overall Satisfaction: LTX customers give a marginally higher satisfaction rating than LDA customers

Q **C2.** Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One?

Overall Satisfaction



Key Insight

- Combining LTX and LDA customer results does not have a significant impact on overall satisfaction, but there are marginal differences across the three dimensions.

Average **Customer Service** Satisfaction Scores	Average **Product** Satisfaction Scores	Average **Brand** Satisfaction Scores
Combined **90%**	Combined **67%**	Combined **76%**
LDA **86%**	LDA **70%**	LDA **72%**
LTX **92%**	LTX **66%**	LTX **77%**

INNOVATIVE RESEARCH GROUP | hydro one

Regression Analysis: Identifying Drivers

Using Regression Analysis: Identifying drivers of customer satisfaction

What is Regression Analysis?

Regressions are another means of determining importance.

- A regression allows us to take all the questions that may explain a key question we are interested in and see which of these is the most important.
- Regressions do this by holding all the likely suspects constant and varying one question at a time to see which questions (explanatory variables) have the greatest impact on the key question (dependent variable).
- In this study, we use regression to understand **why some respondents rate their satisfaction with or likelihood to recommend Hydro One higher than others.**

We use ***Factor Analysis*** to explore underlying dimensions and structure the regression analysis.

- A factor analysis finds the true underlying dimensions of customer satisfaction that explain the pattern of responses to the larger set of attributes.
- Factor analysis allows us to find which attributes mean similar things to customers. The use of factor analysis allows us to determine which attributes should be grouped together in order to conduct meaningful analysis.

Identifying drivers of CSAT

CSAT
*“Overall, how **satisfied** are you with Hydro One?”*
Measures **overall attitude** towards Hydro One.

What drives each of these measures?

The Regression Model: Identifying drivers of customer satisfaction

Price/Billing

Fairness of the Global Adjustment (GA)
Fairness of the Hourly Ontario Energy Price

Customer Service

Communication methods
Customer service (overall)
Service received from Key Account Executive

Participation in CDM programs
Provision of information on CDM tools and programs by the IESO

Product Quality/Reliability

Planned outages (overall)
Quality of power
Unplanned outages (overall)
Reliability of the electricity service
~~Accuracy of duration estimate~~
Time to restore power
~~Communication during outages~~
~~Number of unplanned power outages~~
~~Duration of unplanned outages~~
Recall of planned outage
Recall of unplanned outage

Brand

Accessibility

New to LTX :: *Environmental Controls*
Potential drivers of CSAT outside of Hydro One's control

It is important to distinguish between what is within, and what is outside of Hydro One's influence or control when it comes to drivers of customer satisfaction.

Perceptions of electric companies often tend to move with general perceptions of ***provincial government management in the sector*** rather than in response to the local utility.

In addition, perceptions of utilities are also strongly correlated with **financial circumstances**. In tough times perception and preference can change because customers are struggling with their bills, not because of anything the company has, or has not, done.

Control questions help distributors distinguish between:

a) utility driven programs that impact CSAT; and

b) uncontrollable external drivers that impact CSAT.

When conducting **brand research** in the energy sector, INNOVATIVE often tests multiple environmental control to assess what role predispositions (customer values and beliefs – which can be difficult and costly to change) play in the formation of a utility's brand health and reputation.

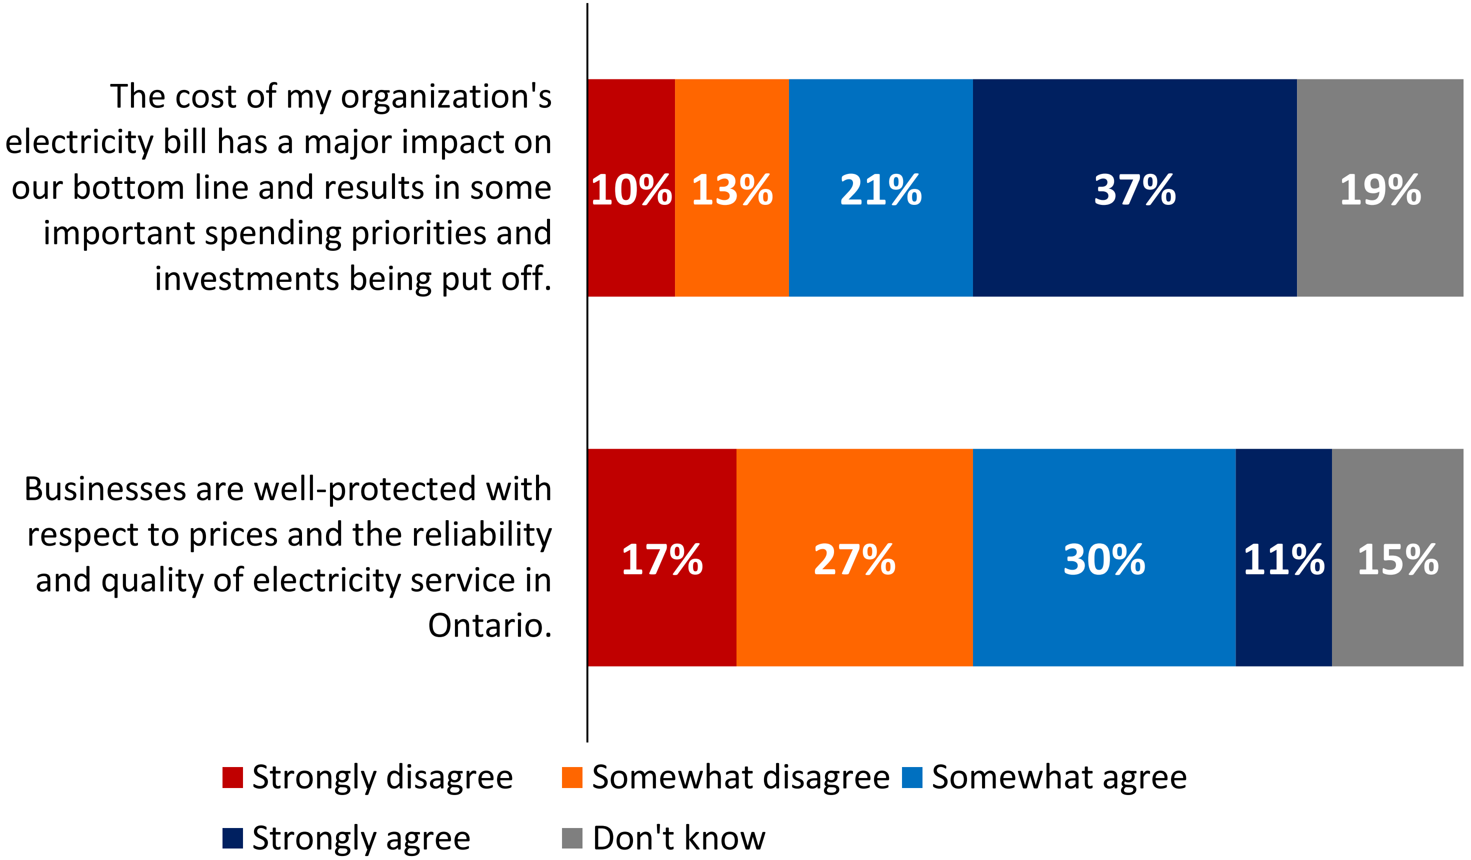
However, in **CSAT research**, we usually limit our environmental controls to two key questions to help capture external phenomena:

Government Management of the Electricity System: *Businesses are well-protected with respect to prices and the reliability and quality of electricity service in Ontario.*

Financial Circumstances: *The cost of my organization's electricity bill has a major impact on our bottom line and results in some important spending priorities and investments being put off.*

Environmental Controls: Most (58%) LTX customers say their electricity bill is impacting their bottom line; opinion is divided on government protection

Q **H55 & H56.** For each statement please tell me if you would strongly agree, somewhat agree, somewhat disagree or strongly disagree.
[Asked of all respondents, n=112]



Key Insights

- A majority (58%) of LTX customers say their bottom line is being impacted by their electricity bill. Almost two-in-five (37%) *strongly* agree that this is the case.
    - LDCs: 36% agree
    - Generators: 55% agree **LDC**
    - End-Users: 91% agree **LDC, GEN**
- Opinion on whether or not businesses are protected in terms of prices, reliability ad quality of electricity service in Ontario is divided: 41% agree, and 44% disagree. However, the level of *strong* disagreement (17%) is marginally higher than the level of *strong* agreement (11%).
    - LDCs: 40% agree
    - Generators: 52% agree **EU**
    - End-Users: 32% agree

NOTE: Response "Don't know" was included in this analysis
Differences between customer type that are statistically significant at a 95% confidence interval are indicated.

The Regression Model: Identifying Drivers

Factors

- **Customer Service**
- **Reliability**
- **Help & Commitment**
- **Valued Partner**
- **Accessibility & Responsiveness**

Standalones

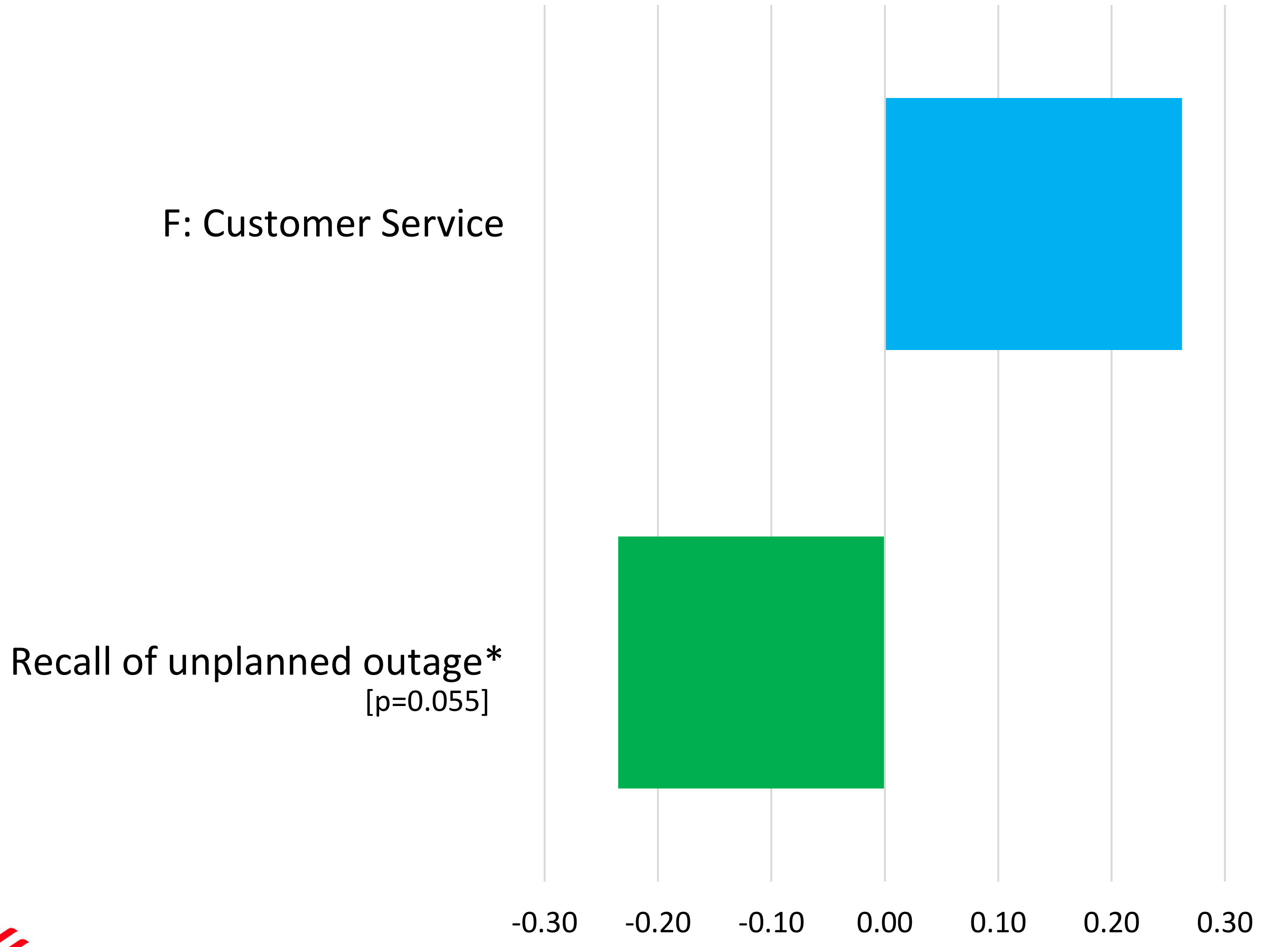
- Fairness of GA
- Fairness of HOEP
- Participation in CDM programs
- Provision of information on CDM tools and programs by the IESO
- Recall of planned outage
- Recall of unplanned outage
- Planned outages (overall)
- Unplanned outages (overall)

Controls

- Customer type
- Environmental controls

Regression Analysis: Identifying drivers of customer satisfaction

Customer service is the only factor that has a positive and statistically significant impact on customer satisfaction. Recall of an unplanned outage has a negative effect.



Adjusted R^2 = 0.289

Notes:
- Factor ***Customer Service*** combines “communication methods”, “customer service (overall)”, “service received from Key Account Executive”.

NOTE: Chart shows standardized beta scores. All drivers significant at a 95% confidence interval unless indicated otherwise.

INNOVATIVE
RESEARCH GROUP

2018 OGCC Customer Satisfaction

Understanding Dimensions of Satisfaction and Dissatisfaction

Hydro One
483 Bay Street
Toronto, ON M5G 2P5

hydro one

December 2018 :: Review Draft

Methodology

The findings presented in this report are based on an online survey carried out by Innovative Research Group (INNOVATIVE) for Hydro One.

The online survey was conducted from October 17th to November 2nd, 2018 among Hydro One LTX customers who had contacted the Ontario Grid Control Centre (OGCC) within the past year. A breakdown of LTX customer segments is included in the table below. In total, 107 participants completed the survey.

The below table shows the surveyed customer segments and their sample sizes:

Segment Size	TOTAL	LDC	Generator	End-User
Total Population Size	218	65	78	74
Surveyed	107	42	31	34
% Captured	49%	65%	40%	46%

Analysis Notation:

Throughout this report “Don’t know” was **included** as a valid response.

NOTE: *Graphs may not always total 100% due to rounding values rather than any error in data. Sums are added before rounding numbers.*

Executive Summary

Summary: *2018 OGCC Report*

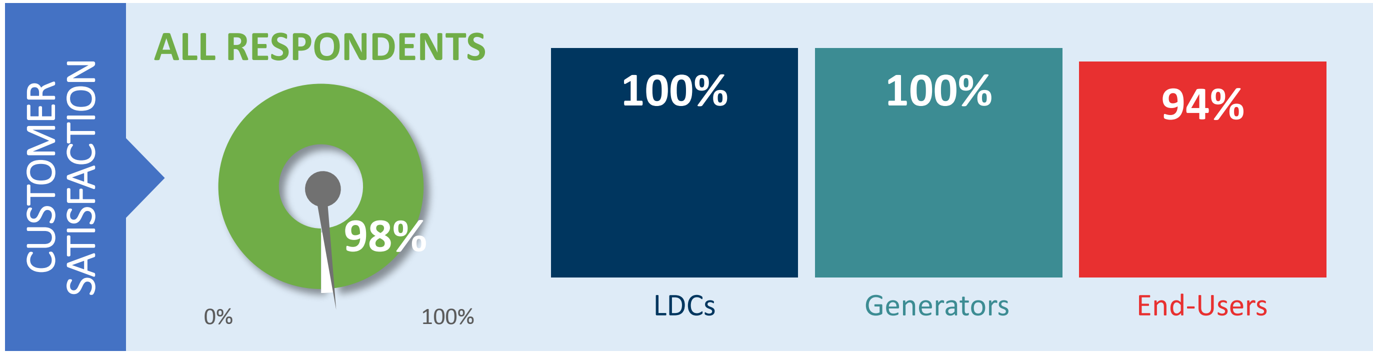
1. **At 98%, customer satisfaction with the OGCC overall is almost universal.**

2. **With the exception of the number of outages and management of <u>unplanned</u> outages, at least half are *"very satisfied"* with every performance metric they were asked about in the survey.**

3. **On a departmental basis, the intensity of satisfaction is highest for the Customer & Operating Support Department (74% *"very satisfied"*).**

4. **Intensity of satisfaction is lowest for the Operating Planning Department (60% *"very satisfied"*).**

5. **The number of <u>unplanned</u> outages has the highest level of dissatisfaction at 31%.**



HIGHEST PERFORMING ATTRIBUTES *("very satisfied")*

- **OGCC**: Relationship with OGCC (96%)
- **Outages**: Planned outage management (57%)
- **Operating Planning**: Proactive communication (65%)
- **Control Room**: Responsiveness (61%)
- **Customer & Operating Support**: Relationship with Network Management Representative (76%)

OPPORTUNITIES FOR IMPROVEMENT *(total dissatisfied)*

- **OGCC**: Sensitivity to operational impact of outages (8%)
- **Outages**: Number of unplanned outages (31%)
- **Operating Planning**: Handling of impactful outages (8%)
- **Control Room**: Prompt updates (3%)
- **Customer & Operating Support**: Effective communication (2%)

Insights: *Drivers of CSAT*

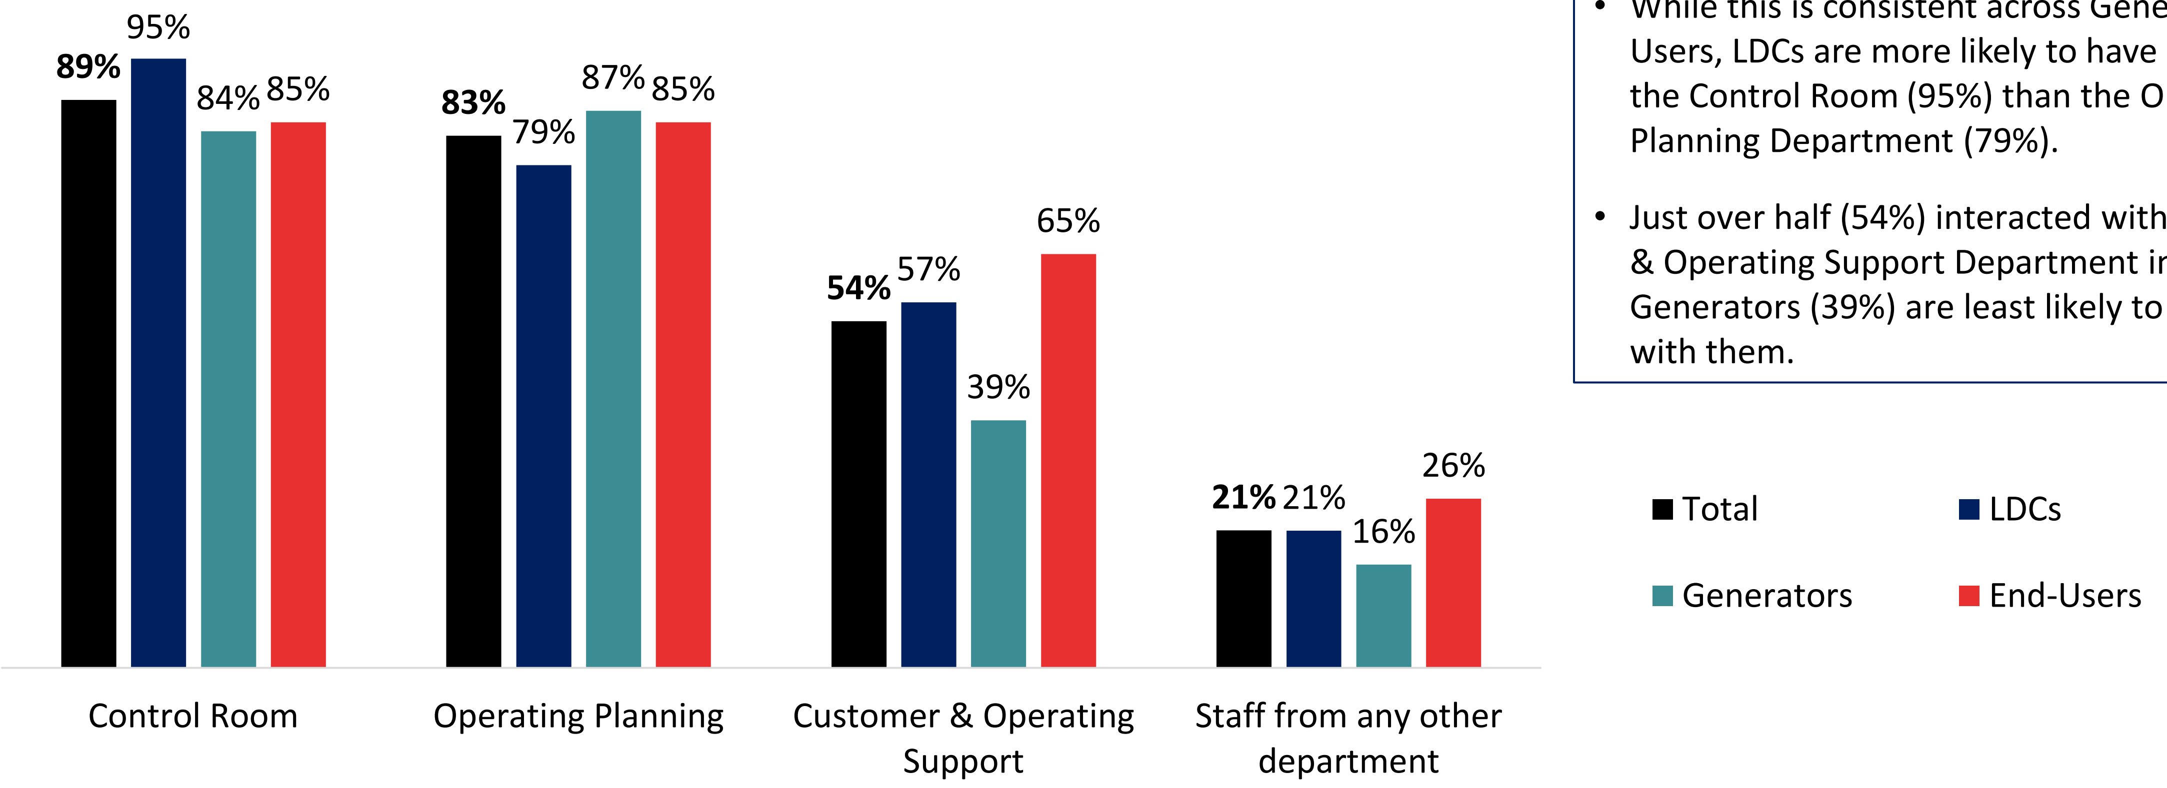
CSAT

- *Communication and Responsiveness* is the strongest driver of overall satisfaction with the service of the OGCC. This factor is a combination of day-to-day communications and responding in a timely manner.
- The level of knowledge of OGCC staff is almost as strong a driver as *Communication and Responsiveness*.
- The third driver is how easy it is to reach the correct contact at the OGCC.
- Being an End-User has a negative impact on overall satisfaction with the OGCC.

OGCC: Department Contact

Q

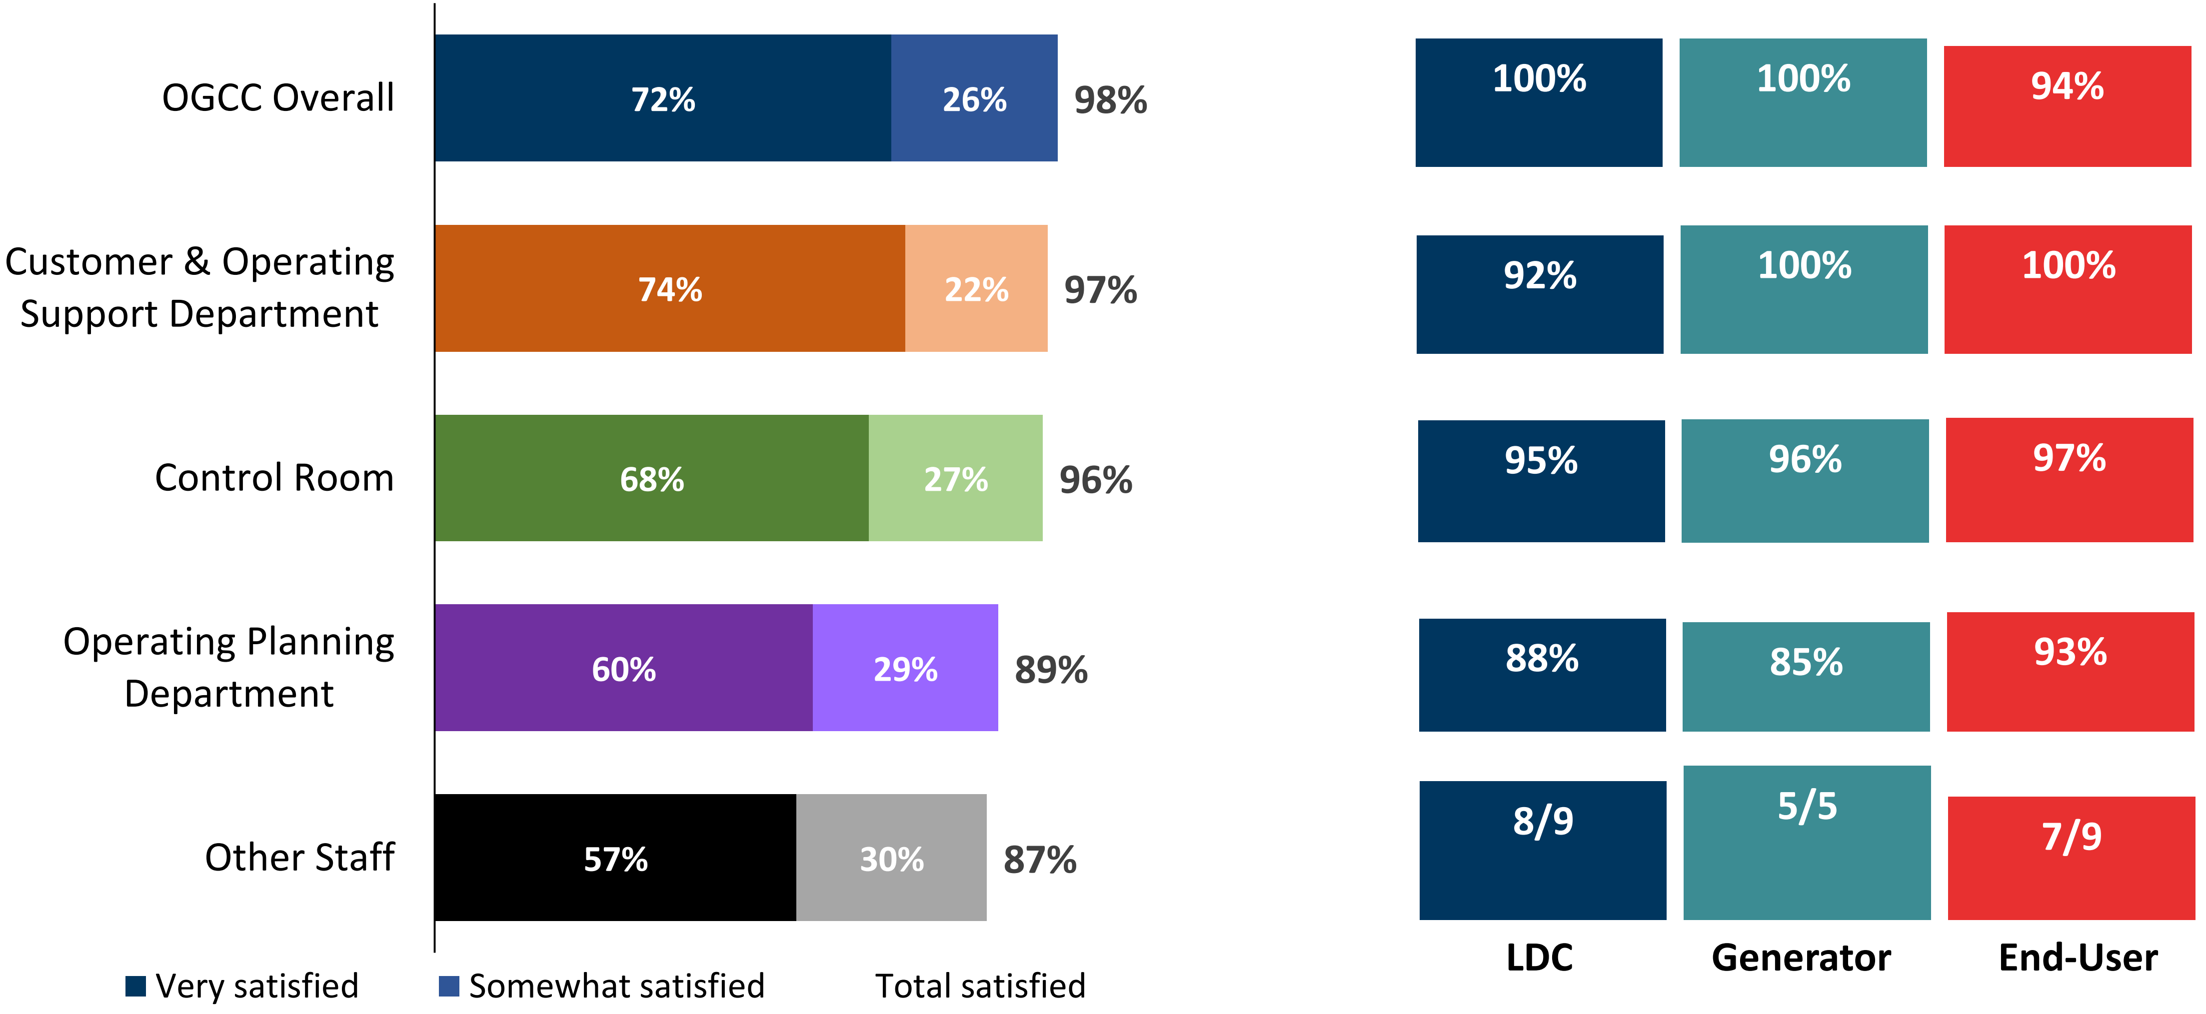
B1. Thinking about the past year, please indicate which of the following Departments at Hydro One's Ontario Grid Control Centre (OGCC) you have had contact with. This contact may have been initiated either by you or by someone at the OGCC.
[Asked of all respondents, multiple-mention, n=107]



Key Insights

- Over 8-in-10 interacted with the Control Room (89%) and/or the Operating Planning Department (83%) in the past year.
- While this is consistent across Generators and End-Users, LDCs are more likely to have interacted with the Control Room (95%) than the Operating Planning Department (79%).
- Just over half (54%) interacted with the Customer & Operating Support Department in the past year. Generators (39%) are least likely to have interacted with them.

Satisfaction: Overall satisfaction is highest for the OGCC overall and the Customer & Operating Support Department



Overall OGCC Customer Satisfaction

INNOVATIVE RESEARCH GROUP

OGCC Summary

Overall Satisfaction

Metrics Included:

Relationship with OGCC (96%)
Day-to-Day Communications (91%)
Knowledge of Staff (91%)
Responds in Timely Manner (89%)
Ease of Reaching Correct Contact (87%)
Understanding Business Needs (85%)
Sensitivity to Outage Impact (82%)

Overall Satisfaction	Overall Dissatisfaction
98%	1%

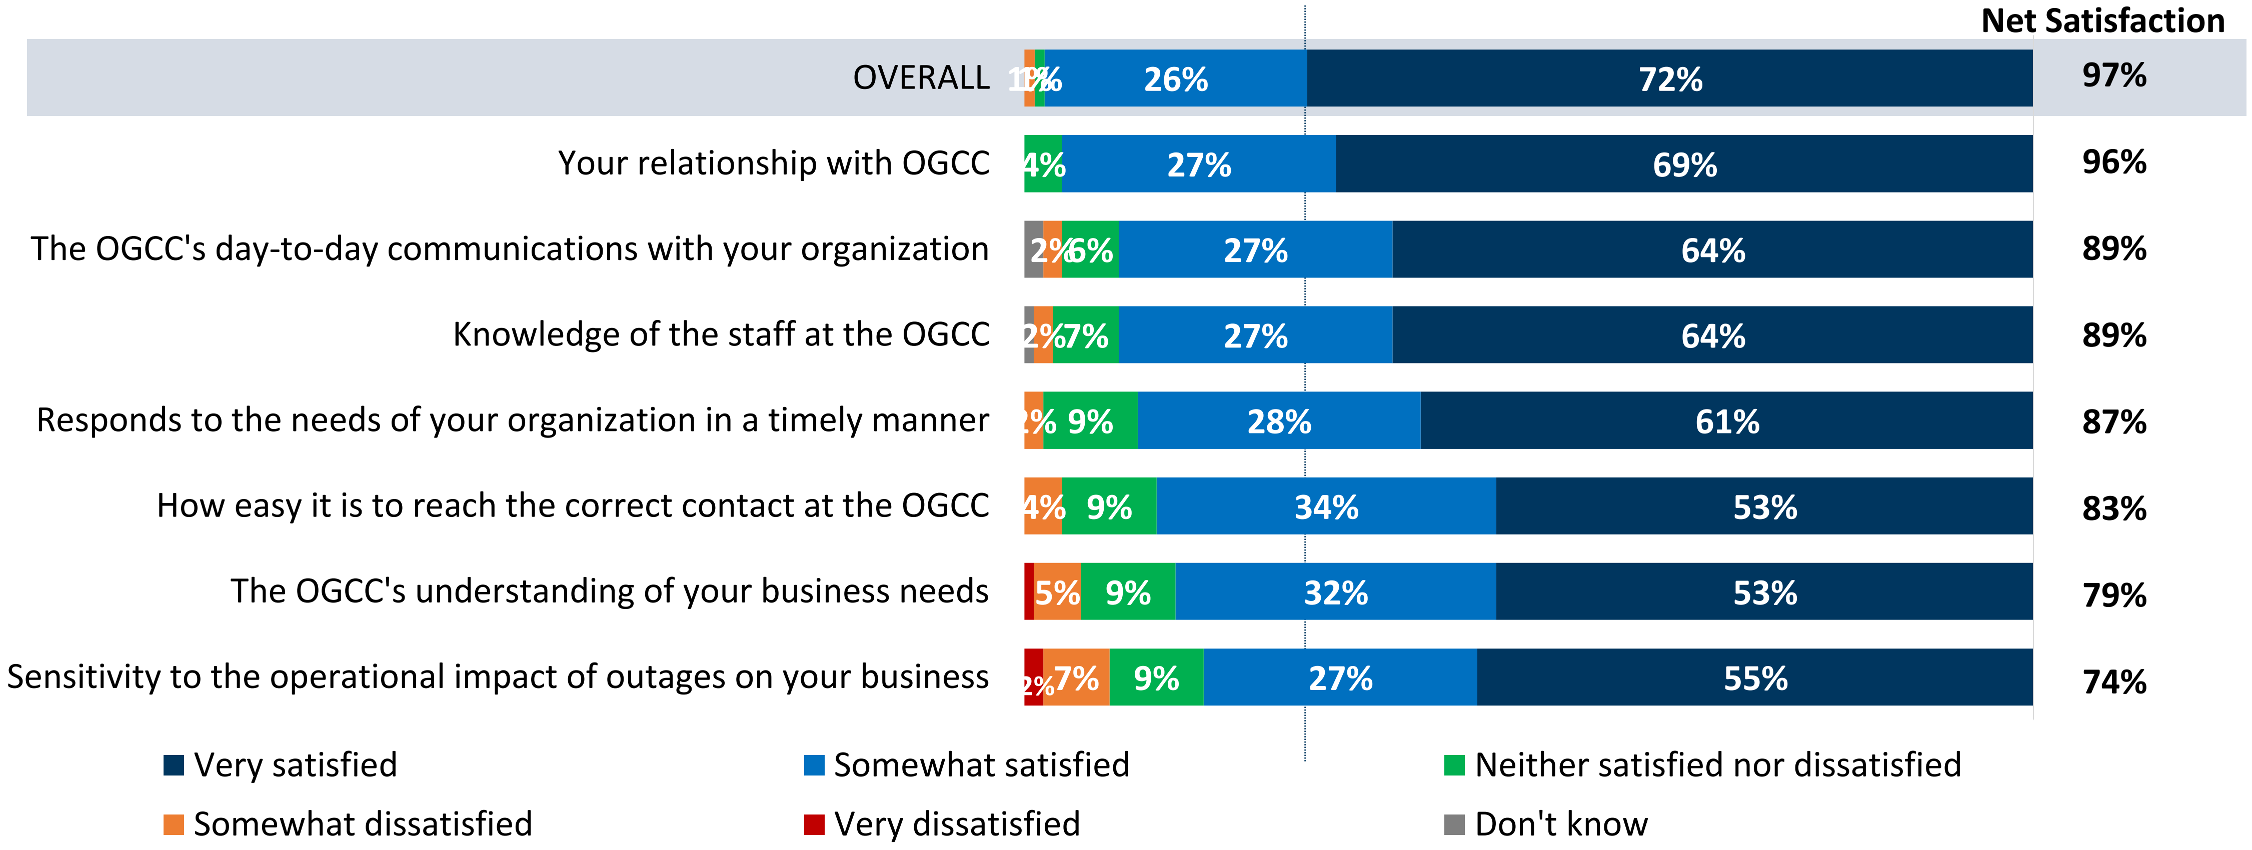
The following questions were asked of all respondents. [n=107]

Key Insights

- Almost all customers who have had contact in the past year are satisfied with the OGCC overall.
- More than three-in-five are *"very satisfied"* with their relationship with OGCC, day-to-day communications, staff knowledge and timeliness of response.
- End-Users are the only group to report being anything less than satisfied with the OGCC overall, but they are at least marginally satisfied than the other two customer groups on most of the individual metrics.
- There is some variation on which metric each customer type reports their lowest level of satisfaction:
  - LDCs: sensitivity to outage impact (81%)
  - Generators: understanding business needs and sensitivity to outage impact (both 77%)
  - End-Users: ease of reaching the correct contact (82%)

OGCC Performance Metrics: A majority are *“very satisfied”* with the OGCC’s performance on all aspects

Q In general, how satisfied or dissatisfied are you with the following aspects of Hydro One’s OGCC?
[Asked of all respondents, n=107]



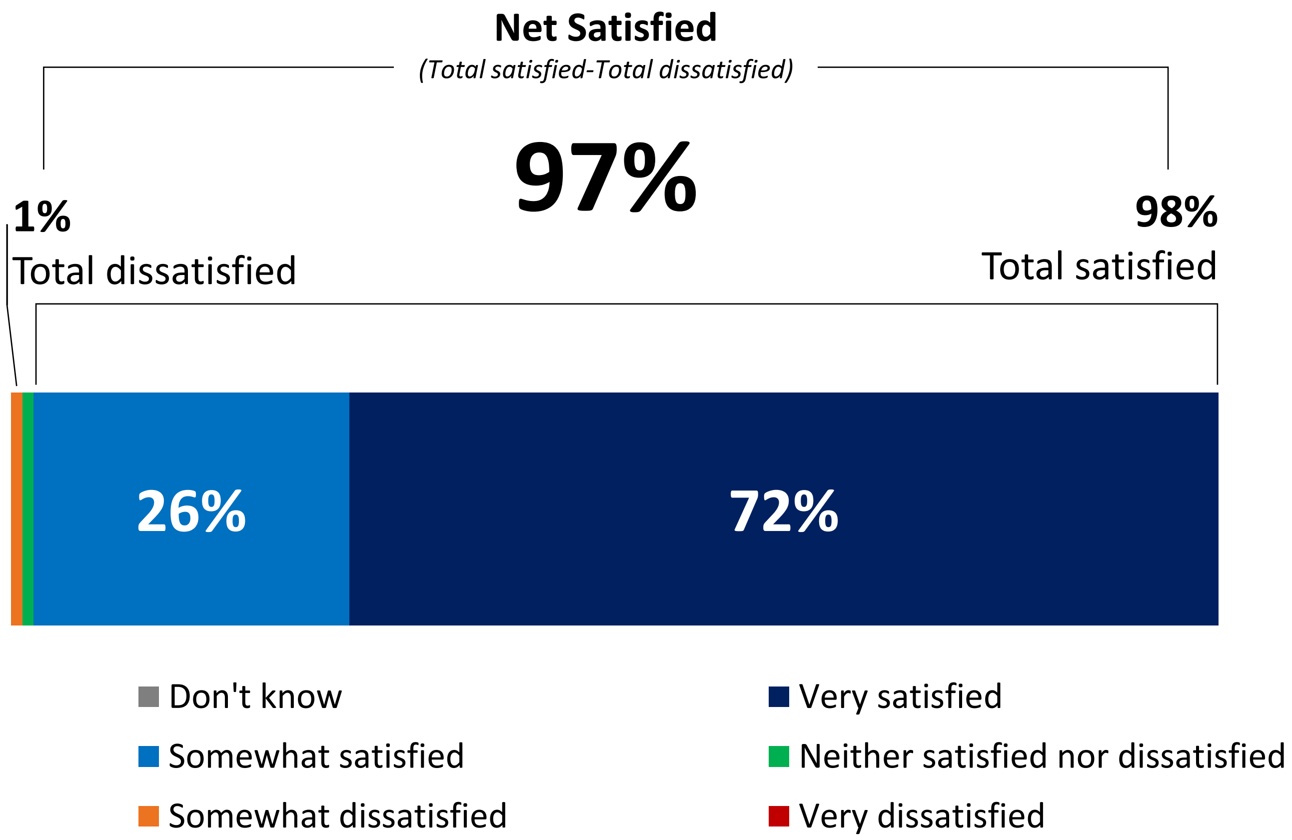
Key Insights

- All performance metrics have strong levels of satisfaction.
- Relationship with OGCC and day-to-day communications have highest net satisfaction.

Overall OGCC Satisfaction: Nearly three quarters (72%) are *"very satisfied"* with the OGCC; only 1% are *"somewhat dissatisfied"*

Q

C2. Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One's Ontario Grid Control Centre (OGCC)?
[Asked of all respondents, n=107]



Key Insights

- The level of satisfaction with OGCC is overwhelmingly positive, with three quarters (72%) saying they are "very satisfied".

Overall Satisfaction | By Customer Type: 3-in-4 LDCs and End-Users are "*very satisfied*" with OGCC, about 10 points higher than Generators

Q **C2.** Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One's Ontario Grid Control Centre (OGCC)?
[Asked of all respondents, n=107]

	Total Dissatisfied	Total Satisfied	Net Satisfaction
LDCs	-	100%	+100%
Generators	-	100%	+100%
End-Users	3%	94%	+91%

Key Insights

- LDCs and End-Users are more intensely satisfied with OGCC overall than Generators, but there is a little bit (3%) of dissatisfaction among End-Users.

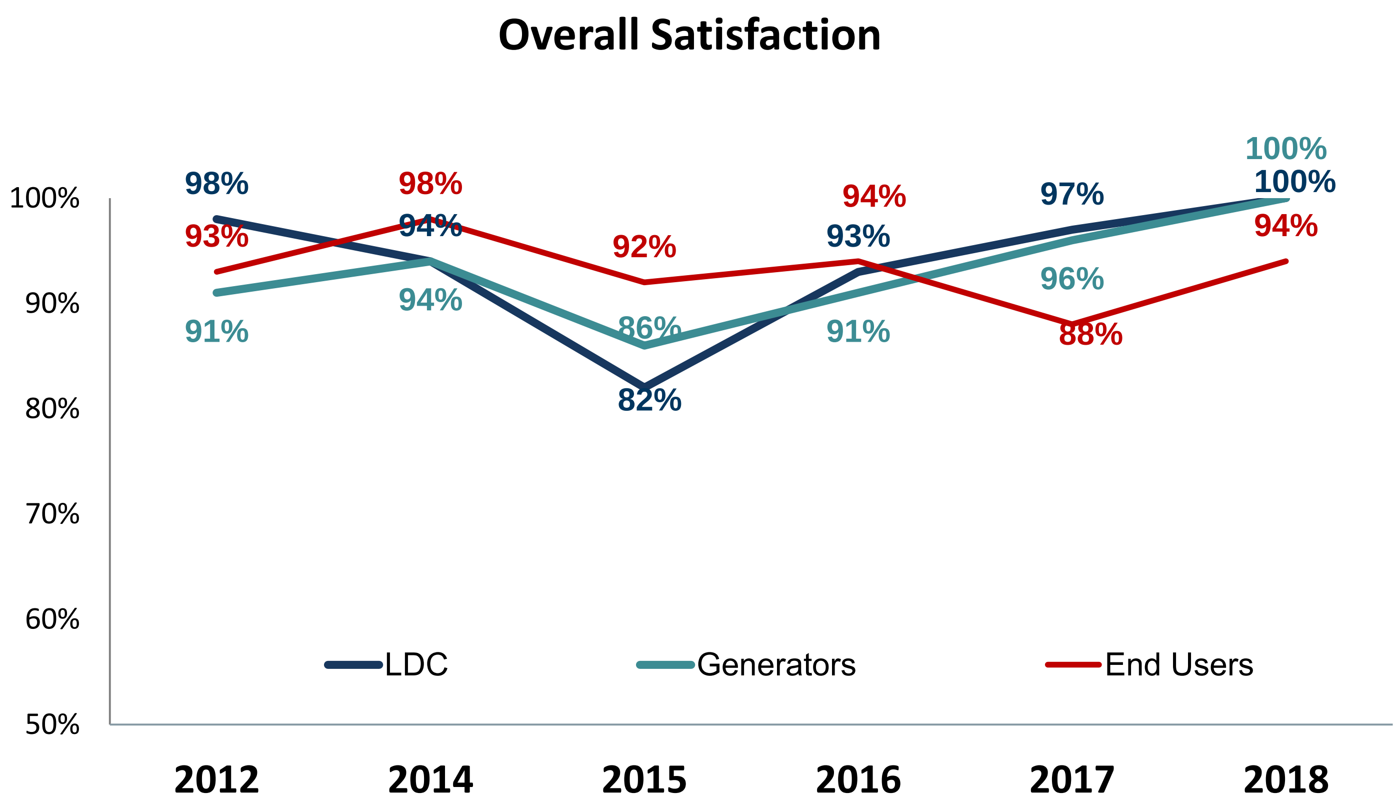
INNOVATIVE RESEARCH GROUP | hydro one

OGCC OVERALL

Overall Satisfaction | Tracking by Customer Type: At least marginal gains in overall satisfaction with OGCC across all customer types

Q **C2.** Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One's Ontario Grid Control Centre (OGCC)?

[Asked of all respondents, n=107]



Key Insights

- LDCs and Generators hit universal satisfaction for the first time since tracking began in 2012.
- The customer types have both been trending upward since 2015.
- End-Users have recovered from dip in satisfaction last year.

LTX Customer Type	Total Population	2018 Sample Size
LDCs	65	42
Generators	78	31
End-Users	74	34

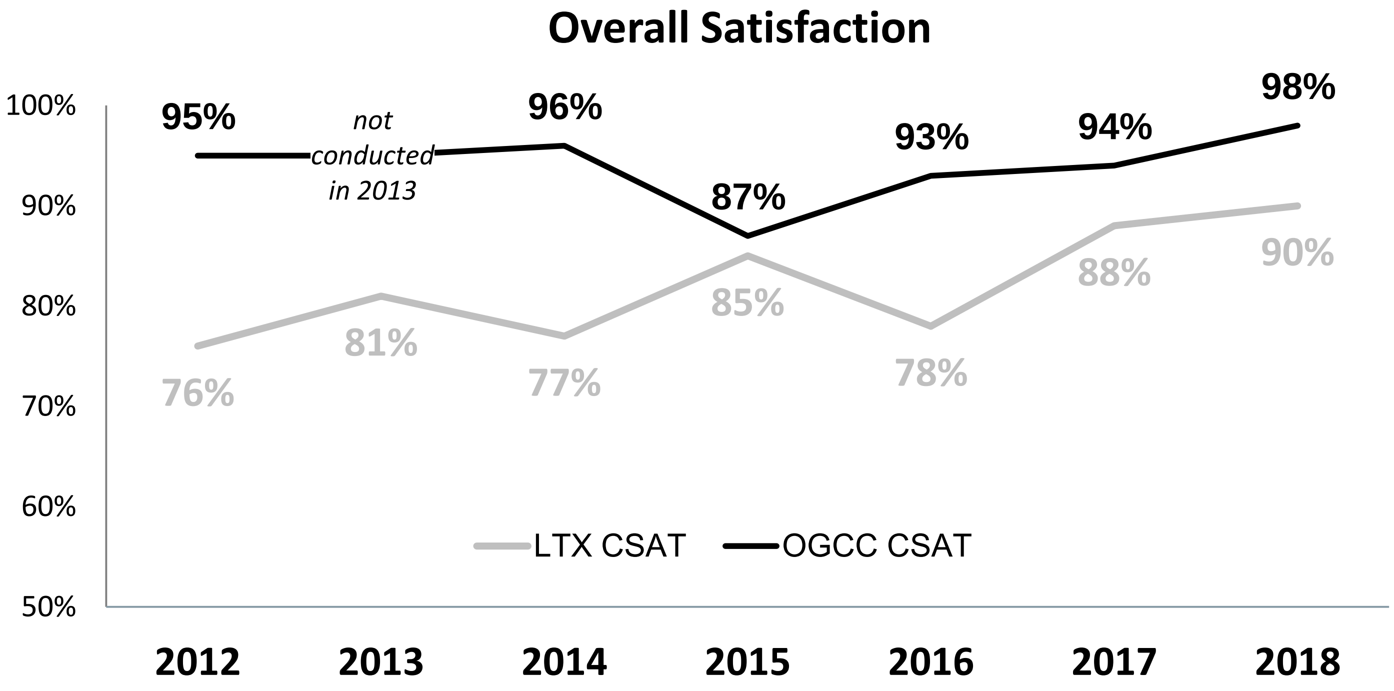
INNOVATIVE RESEARCH GROUP | hydro one

NOTE: Response "Don't know" (0% 2018) was excluded from this analysis in order to be consistent with previous methodology.
Survey not conducted in 2013.

Overall Satisfaction | LTX CSAT vs OGCC CSAT: Marginal widening of the gap between utility and OGCC satisfaction levels

Q **C2.** Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One's Ontario Grid Control Centre (OGCC)?
[Asked of all respondents, n=107]

Q **C2.** Overall, how satisfied or dissatisfied are you with the service your organization receives from Hydro One?
[Asked of all respondents, n=112; valid responses n=112]



Key Insights

- After narrowing the gap in 2015, satisfaction with the utility increased and has continued to trend upward since 2016.
- OGCC satisfaction dropped in 2016, bounced back in 2017 and improved marginally in 2018.

INNOVATIVE RESEARCH GROUP | hydro one

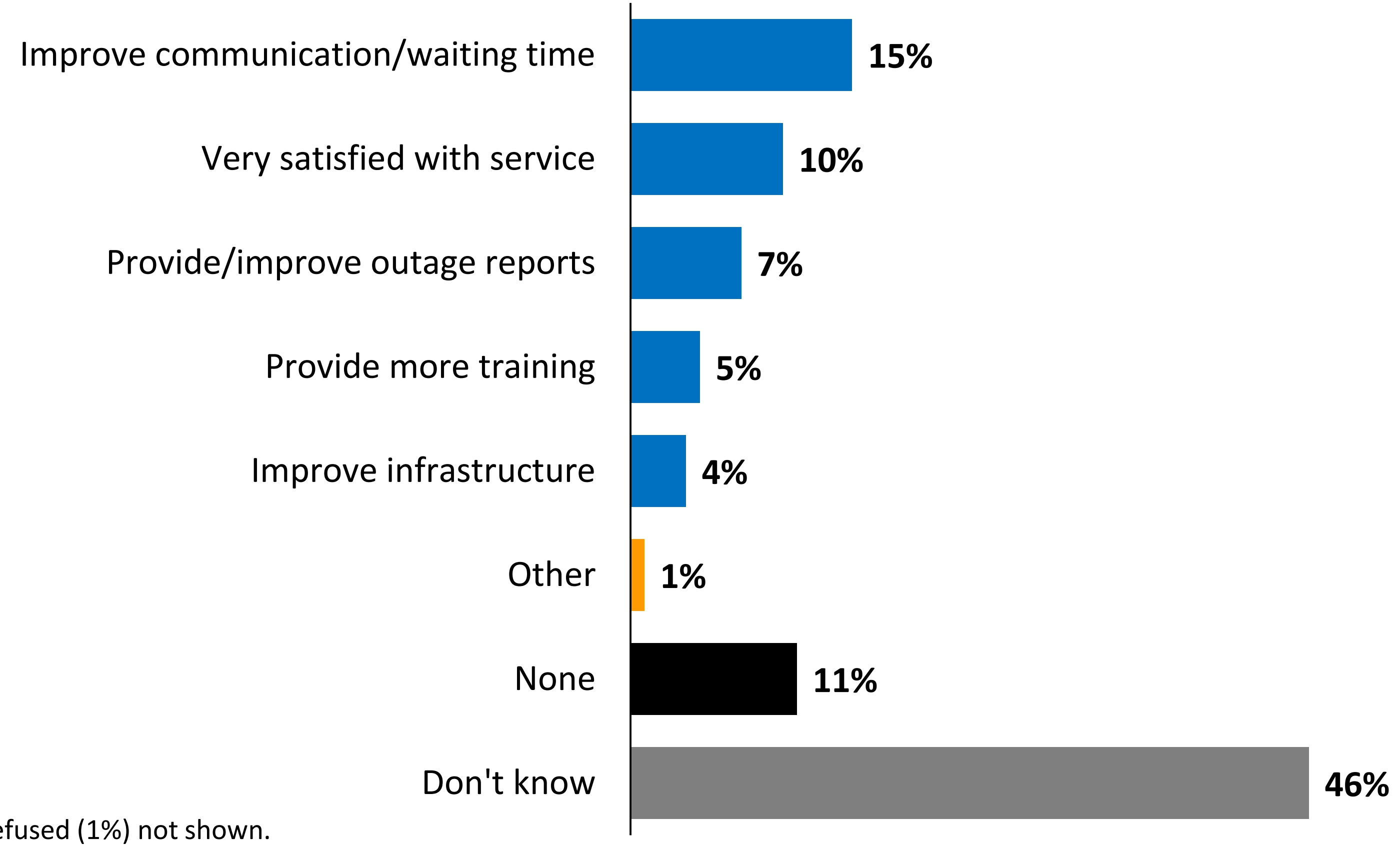
NOTE: Response "Don't know" (0% in 2018) was excluded from this analysis in order to be consistent with previous methodology.

Overall Areas of Improvement: Communication and waiting time lead suggested improvements; over half (57%) say nothing or don't know

Q

C3. Is there anything in particular that Hydro One's Ontario Grid Control Centre (OGCC) can do to improve its services to your organization?

[Asked of all respondents, open-ended, n=107]



NOTE: Refused (1%) not shown.

Key Insights

- More than half do not have any specific suggestions for improvements at OGCC.
- The most common suggestions are to improve communication/waiting time. Others would like improvements on outage reports, and for more training.

Relationship With OGCC: 7-in-10 (69%) are "*very satisfied*" with relationship; Generators (65%) are marginally less intensely satisfied

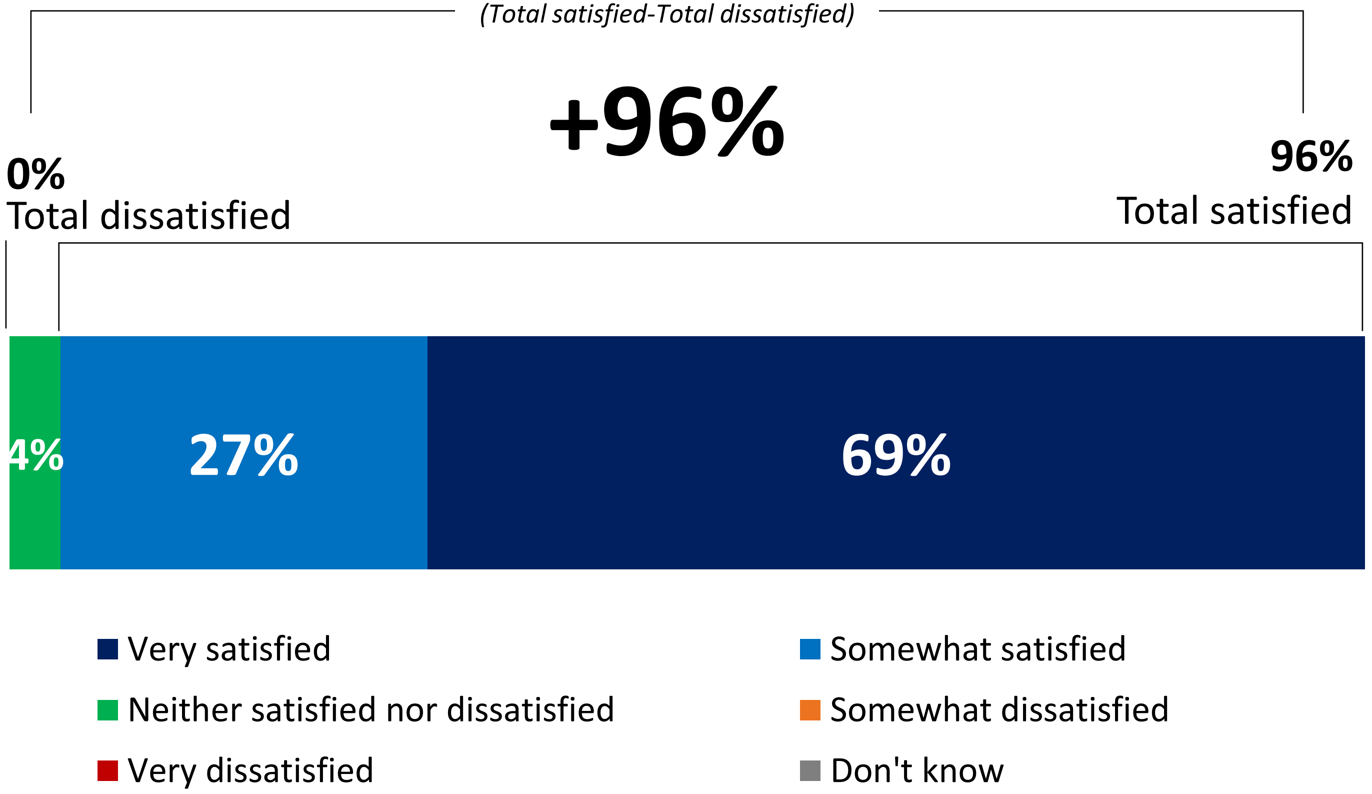
Q In general, how satisfied or dissatisfied are you with the following aspects of Hydro One's OGCC?

C4. Your relationship with OGCC

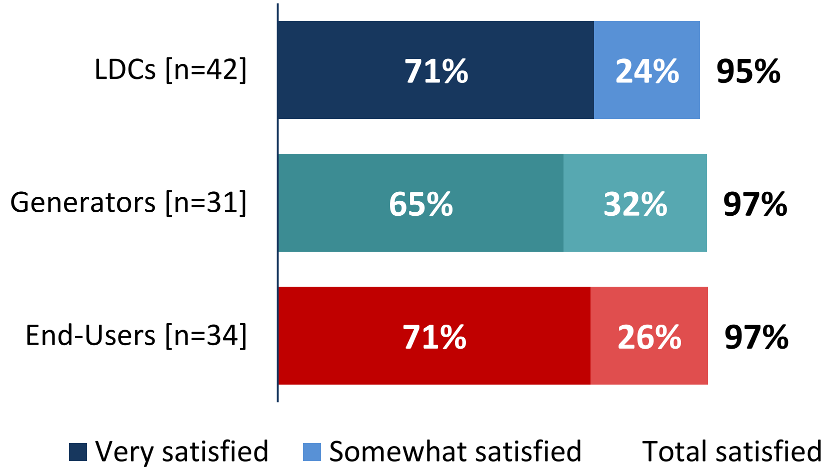
[Asked of all respondents, n=107]

Net Satisfied

(Total satisfied-Total dissatisfied)



Total Satisfaction ▶▶ By Customer Type



Key Insights

- While the total satisfaction levels with their relationship with OGCC are consistent across the customer segments, LDCs (71%) and End-Users (71%) are 6 points more likely to say they "very satisfied" than Generators (65%).

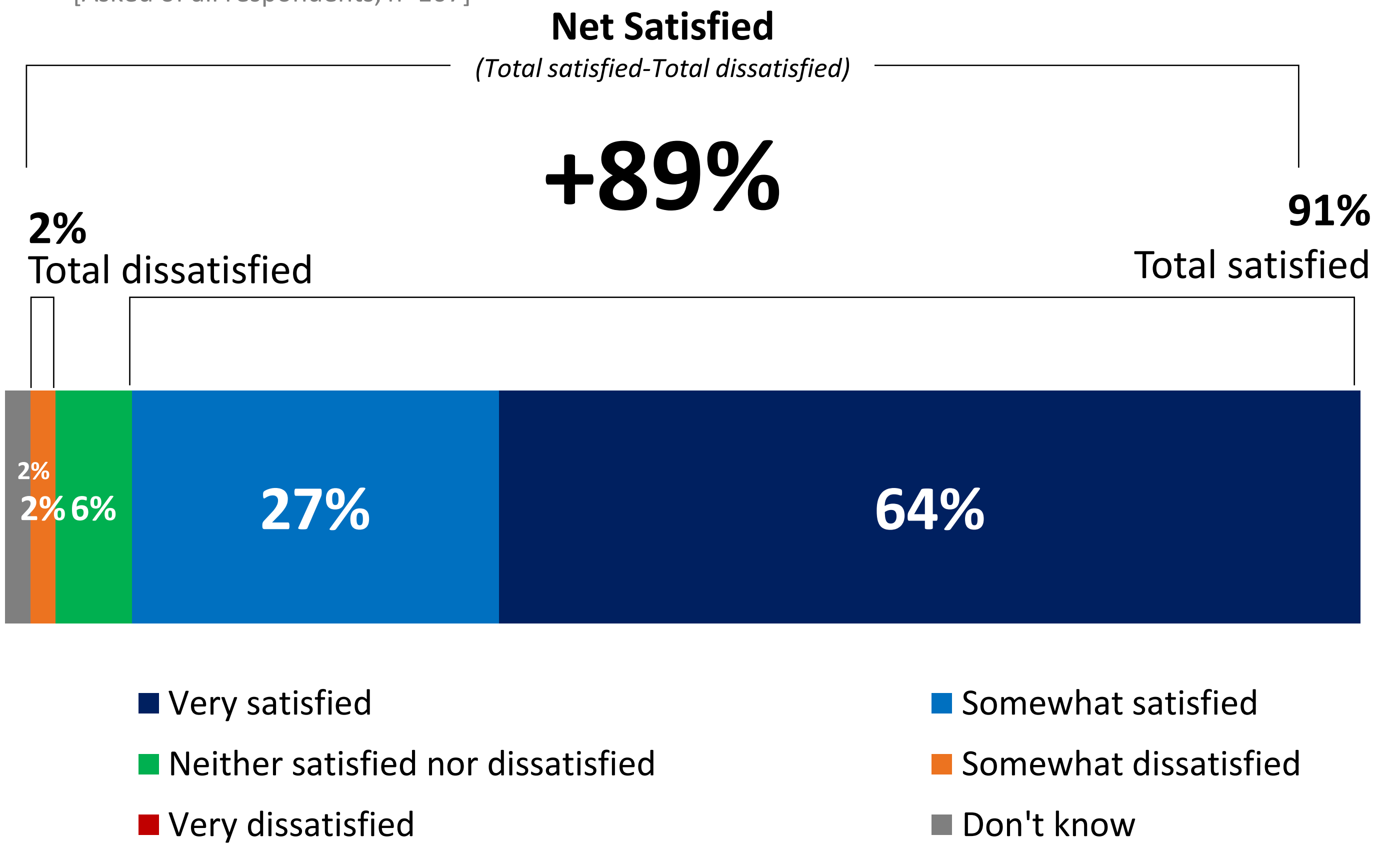
Day-to-Day Communications: Two-thirds (64%) are "*very satisfied*" with communications; higher among End-Users (71%)

Q

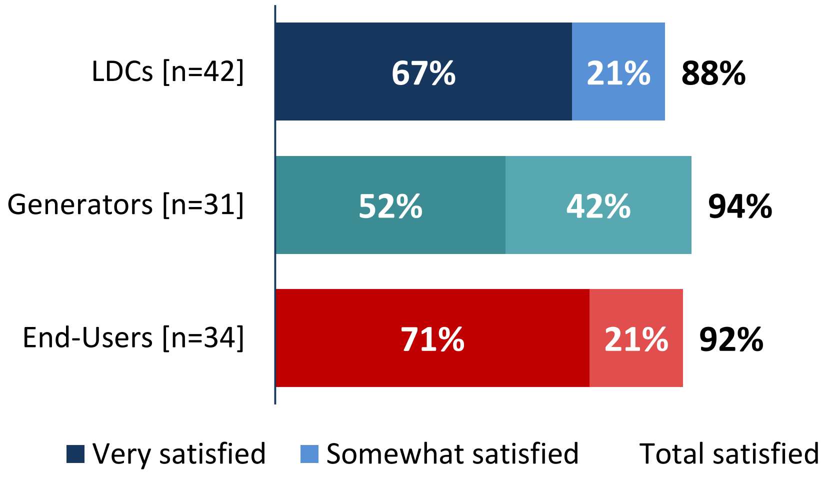
In general, how satisfied or dissatisfied are you with the following aspects of Hydro One's OGCC?

C5. The OGCC's day-to-day communications with your organization

[Asked of all respondents, n=107]



Total Satisfaction ▶▶ By Customer Type



Key Insights

- The proportion of LDCs (67%) and End-Users (71%) saying they are "very satisfied" with OGCC's day-to-day communications is 15+ points higher than among Generators (52%).

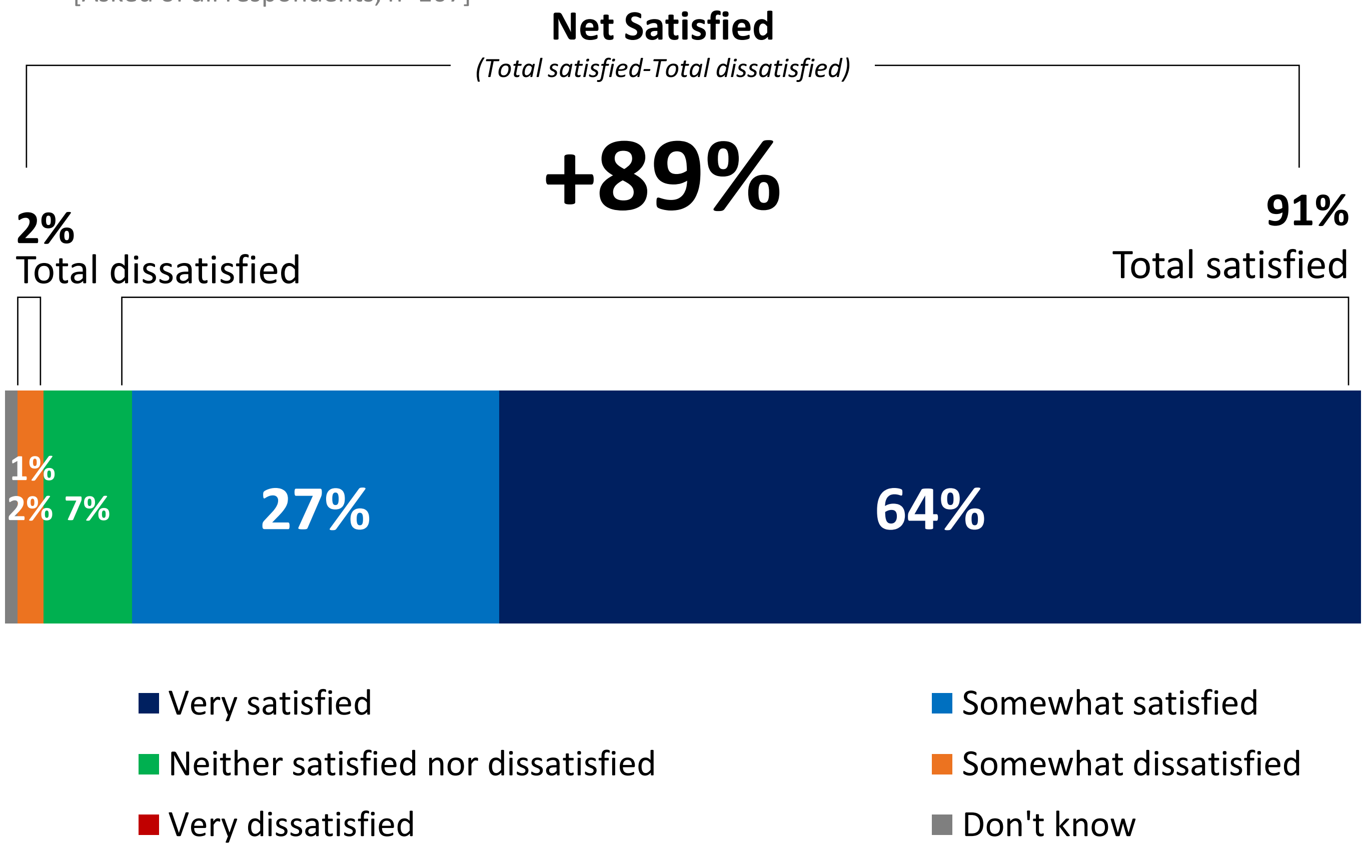
INNOVATIVE RESEARCH GROUP | hydro one

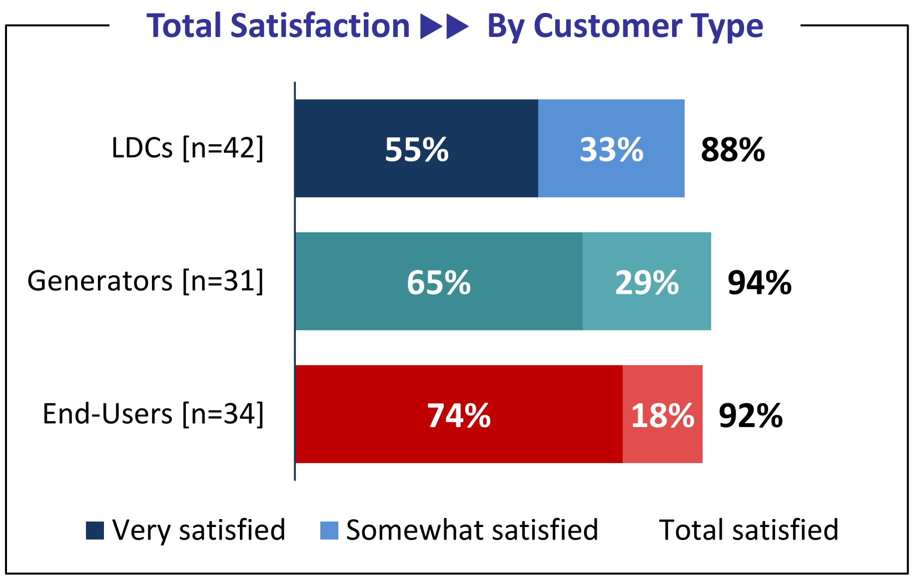
Staff Knowledge: Two-thirds (64%) respondents are "*very satisfied*" with knowledge of staff at the OGCC; highest among End-Users (74%)

Q In general, how satisfied or dissatisfied are you with the following aspects of Hydro One's OGCC?

C6. Knowledge of staff at the OGCC

[Asked of all respondents, n=107]



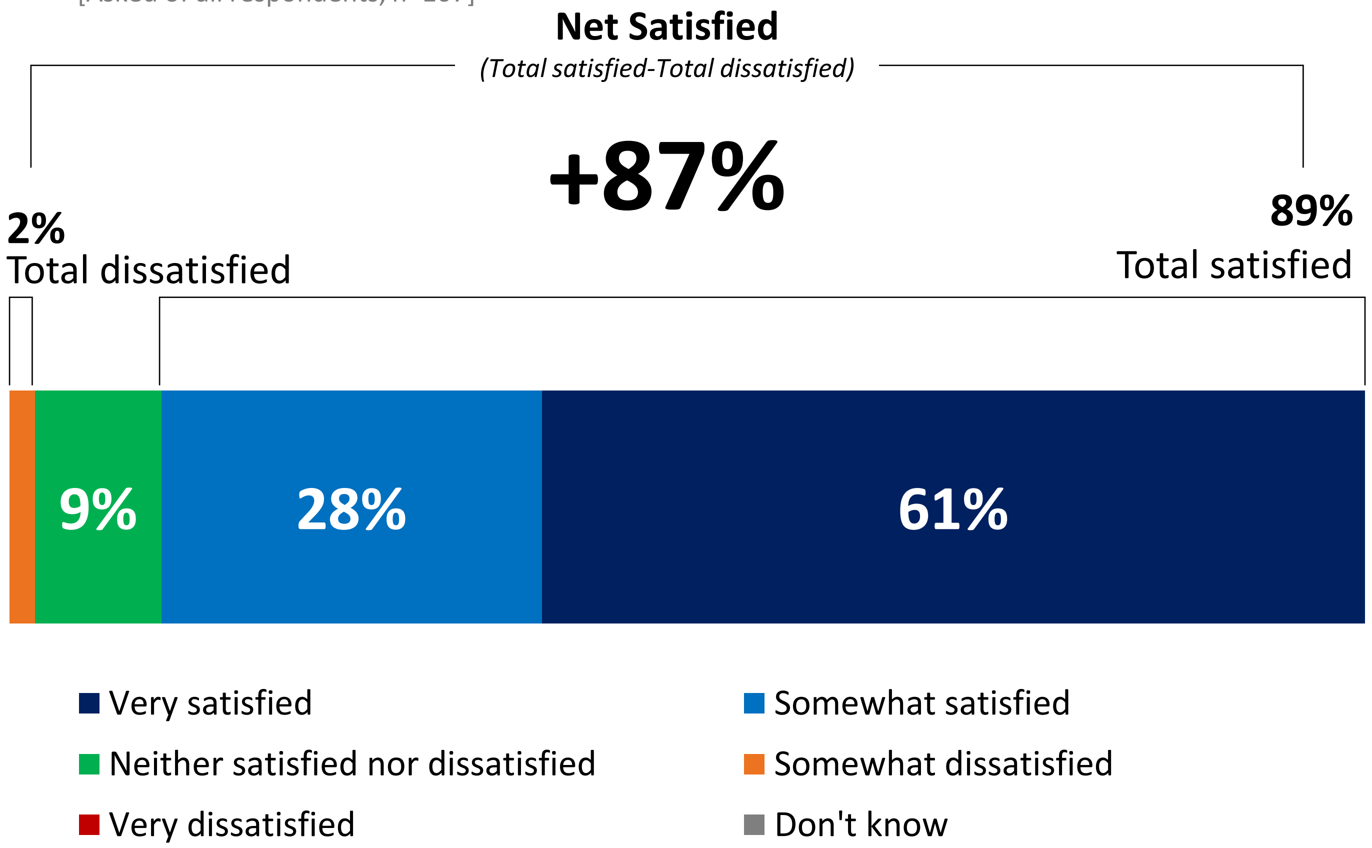


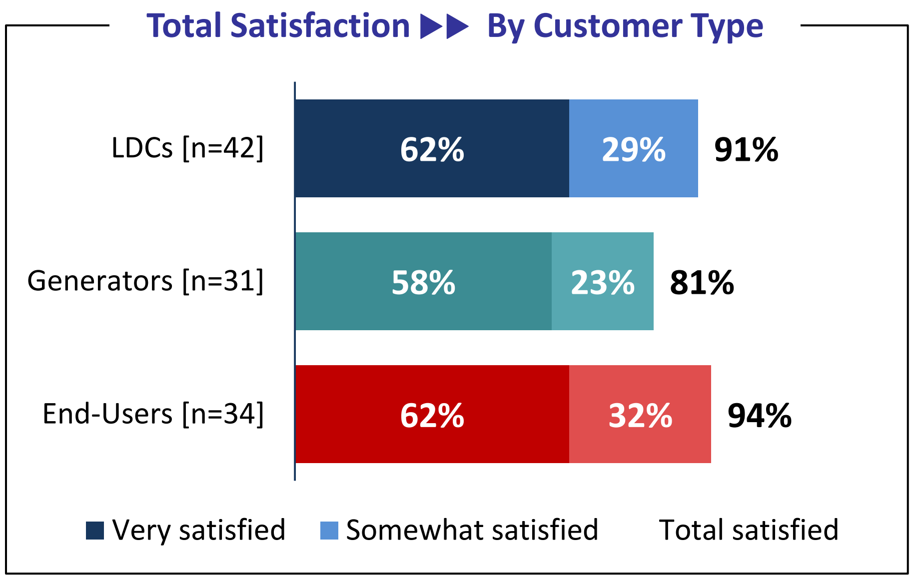
Key Insights

- The proportion of End-Users (74%) saying they are "very satisfied" with the knowledge of OGCC's staff is nearly 20 points higher than among LDCs (55%).
- The total level of satisfaction is marginally higher among Generators and End-Users than among LDCs.

Timely Response to Needs: 3-in-5 (61%) are "*very satisfied*" with the timeliness of response; Generators (58%) marginally lower than average

Q In general, how satisfied or dissatisfied are you with the following aspects of Hydro One's OGCC?
C10. The OGCC responds to the needs of your organization in a timely manner
[Asked of all respondents, n=107]





Key Insights

- About 3-in-5 are "very satisfied" with OGCC's timely responses to their needs. This is largely consistent across the three customer types.

INNOVATIVE RESEARCH GROUP | hydro one

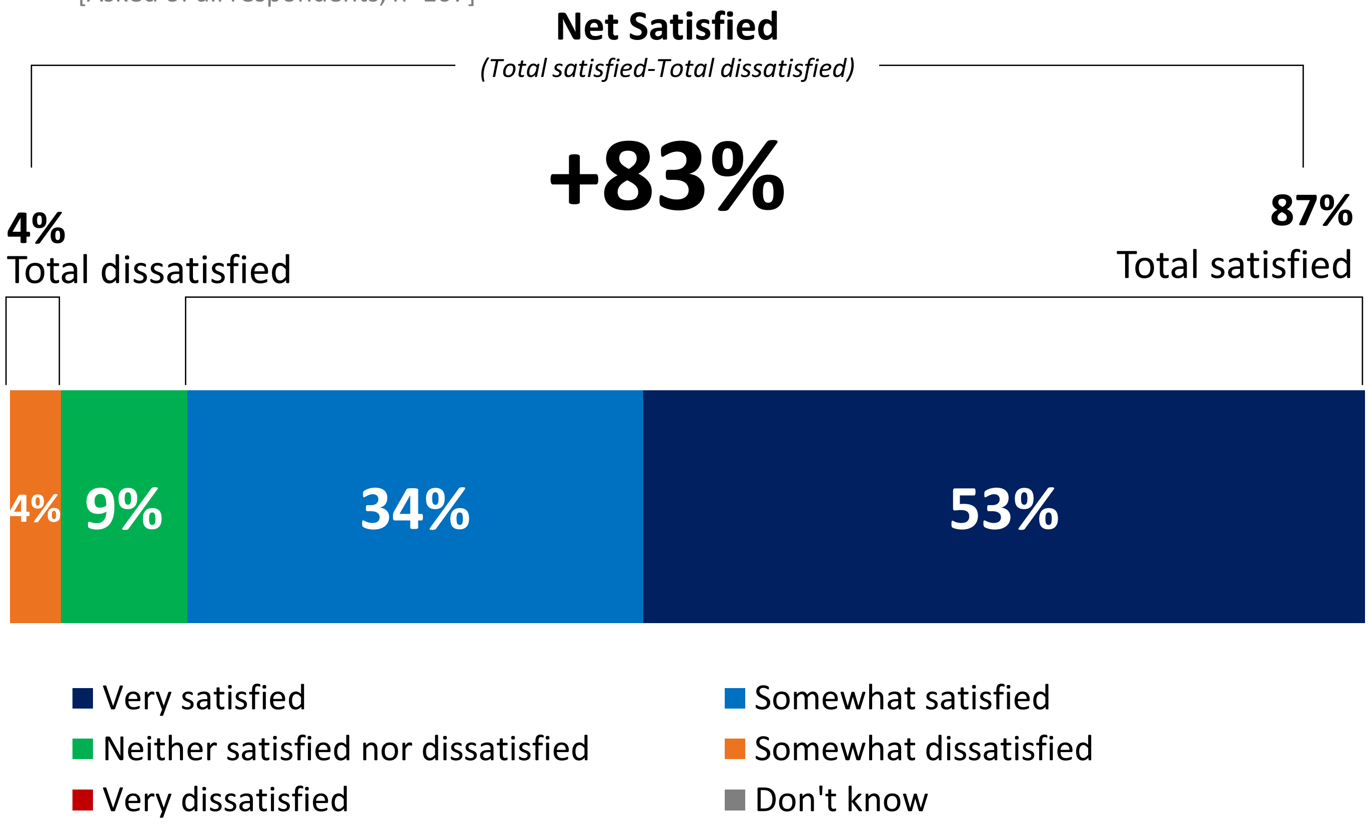
Reaching the Correct Contact: Over half (53%) are "*very satisfied*"; highest among LDCs (62%) and lowest among Generators (45%)

Q

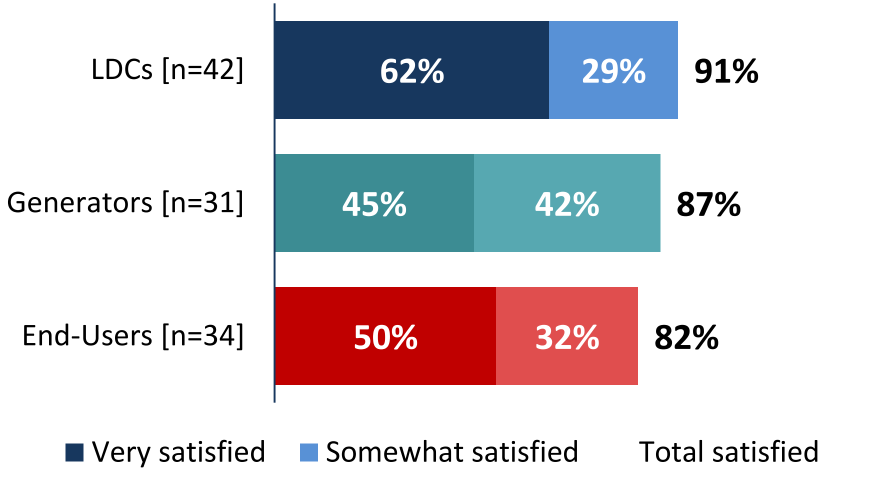
In general, how satisfied or dissatisfied are you with the following aspects of Hydro One's OGCC?

C8. How easy it is to reach the correct contact at the OGCC

[Asked of all respondents, n=107]



Total Satisfaction ▶▶ By Customer Type

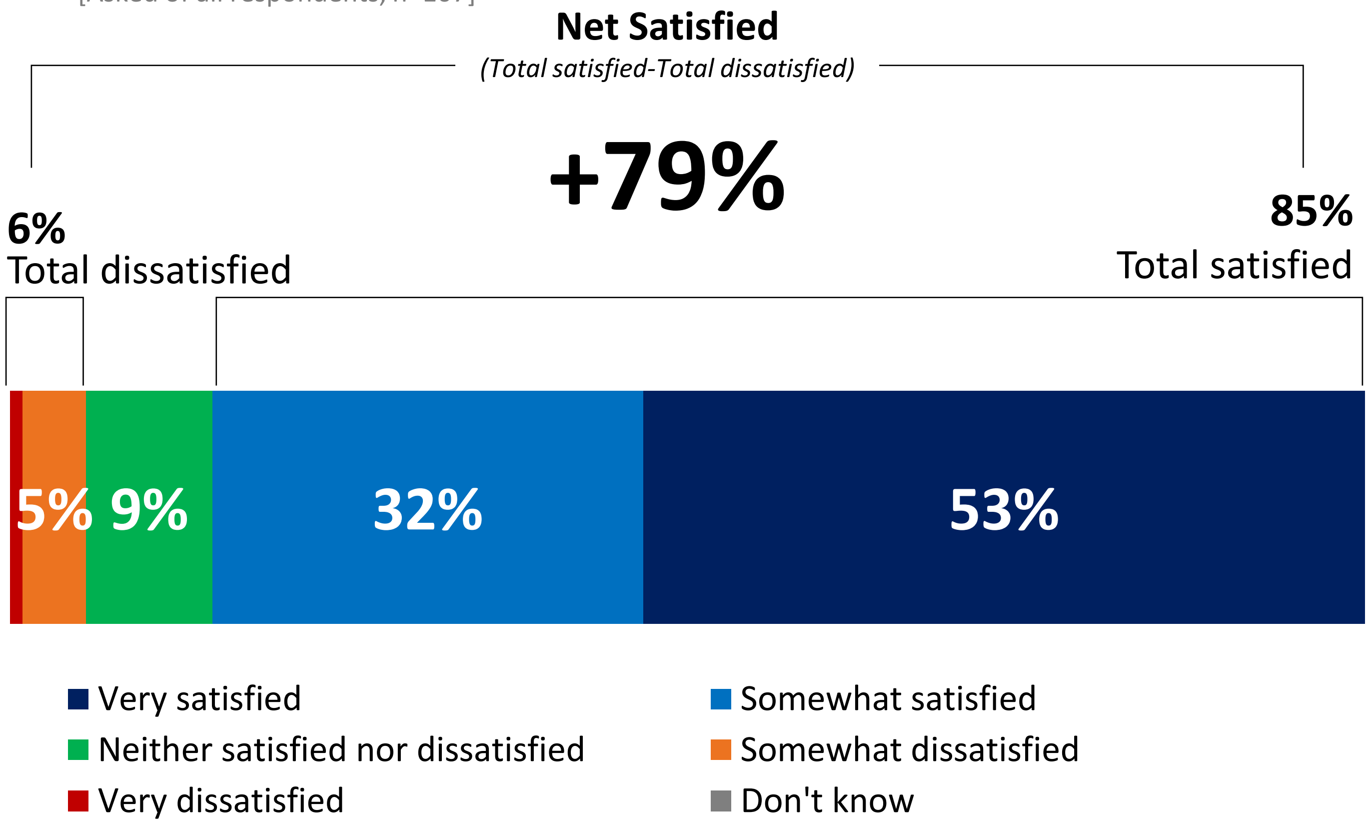


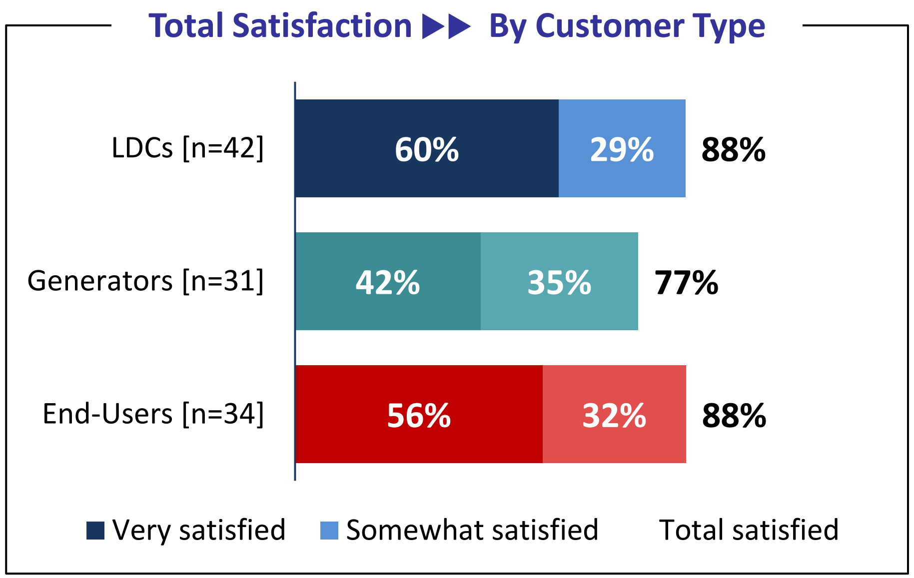
Key Insights

- The proportion of LDCs (62%) saying they are "very satisfied" with the ease of reaching the correct contact is 17 points higher than among Generators (45%).
- The level of intense satisfaction among End-Users (50%) on par with the average (53%).

Understanding Business Needs: Over half (53%) are "*very satisfied*" with OGCC's understanding of their needs; lowest among Generators (42%)

Q In general, how satisfied or dissatisfied are you with the following aspects of Hydro One's OGCC?
C9. The OGCC's understanding of your business needs
[Asked of all respondents, n=107]





Key Insights

- Intense satisfaction among End-Users (56%) and LDCs (60%) is 14 or more points higher than among Generators (31%).

Regression Analysis

Using Regression Analysis: *Identifying drivers of customer satisfaction*

What is Regression Analysis?

Regressions are another means of determining importance.

- A regression allows us to take all the questions that may explain a key question we are interested in and see which of these is the most important.
- Regressions do this by holding all the likely suspects constant and varying one question at a time to see which questions (explanatory variables) have the greatest impact on the key question (dependent variable).
- In this study, we use regression to understand **why some respondents rate their satisfaction with Hydro One's OGCC higher than others.**

We use ***Factor Analysis*** to explore underlying dimensions and structure the regression analysis.

- A factor analysis finds the true underlying dimensions of customer satisfaction that explain the pattern of responses to the larger set of attributes.
- Factor analysis allows us to find which attributes mean similar things to customers. The use of factor analysis allows us to determine which attributes should be grouped together in order to conduct meaningful analysis.

INNOVATIVE RESEARCH GROUP | hydro one

Key Question (Dependent Variable): *OGCC Customer Satisfaction (CSAT)*

	OGCC CSAT
Key Question (Dependent Variable)	*"Overall, how **satisfied or dissatisfied** are you with the service your organization receives from Hydro One's Ontario Grid Control Centre (OGCC)?"*
Purpose of the question	Measures **overall satisfaction** towards the OGCC.

What drives overall satisfaction?

The Regression Model and Factor Analysis: *Identifying drivers of customer satisfaction*

We have identified two factors – "Business needs" and "Communications and Responsiveness". All other drivers are standalone explanatory variables.

Controls

- Customer Type

Interactions with OGCC

- Operating Planning Department
- Control Room
- Customer & Operating Support Department
- Staff from any other department

Unplanned Outage Experience

- Satisfaction with the management
- Satisfaction with the number of unplanned power outages

Planned Outage Experience

- Satisfaction with the management
- Satisfaction with the number of planned power outages

Satisfaction with Various Aspects of OGCC

- Their relationship with OGCC
- The OGCC's sensitivity to the operational impact of outages on their business
- The OGCC's understanding of their business needs

Factor: Business needs

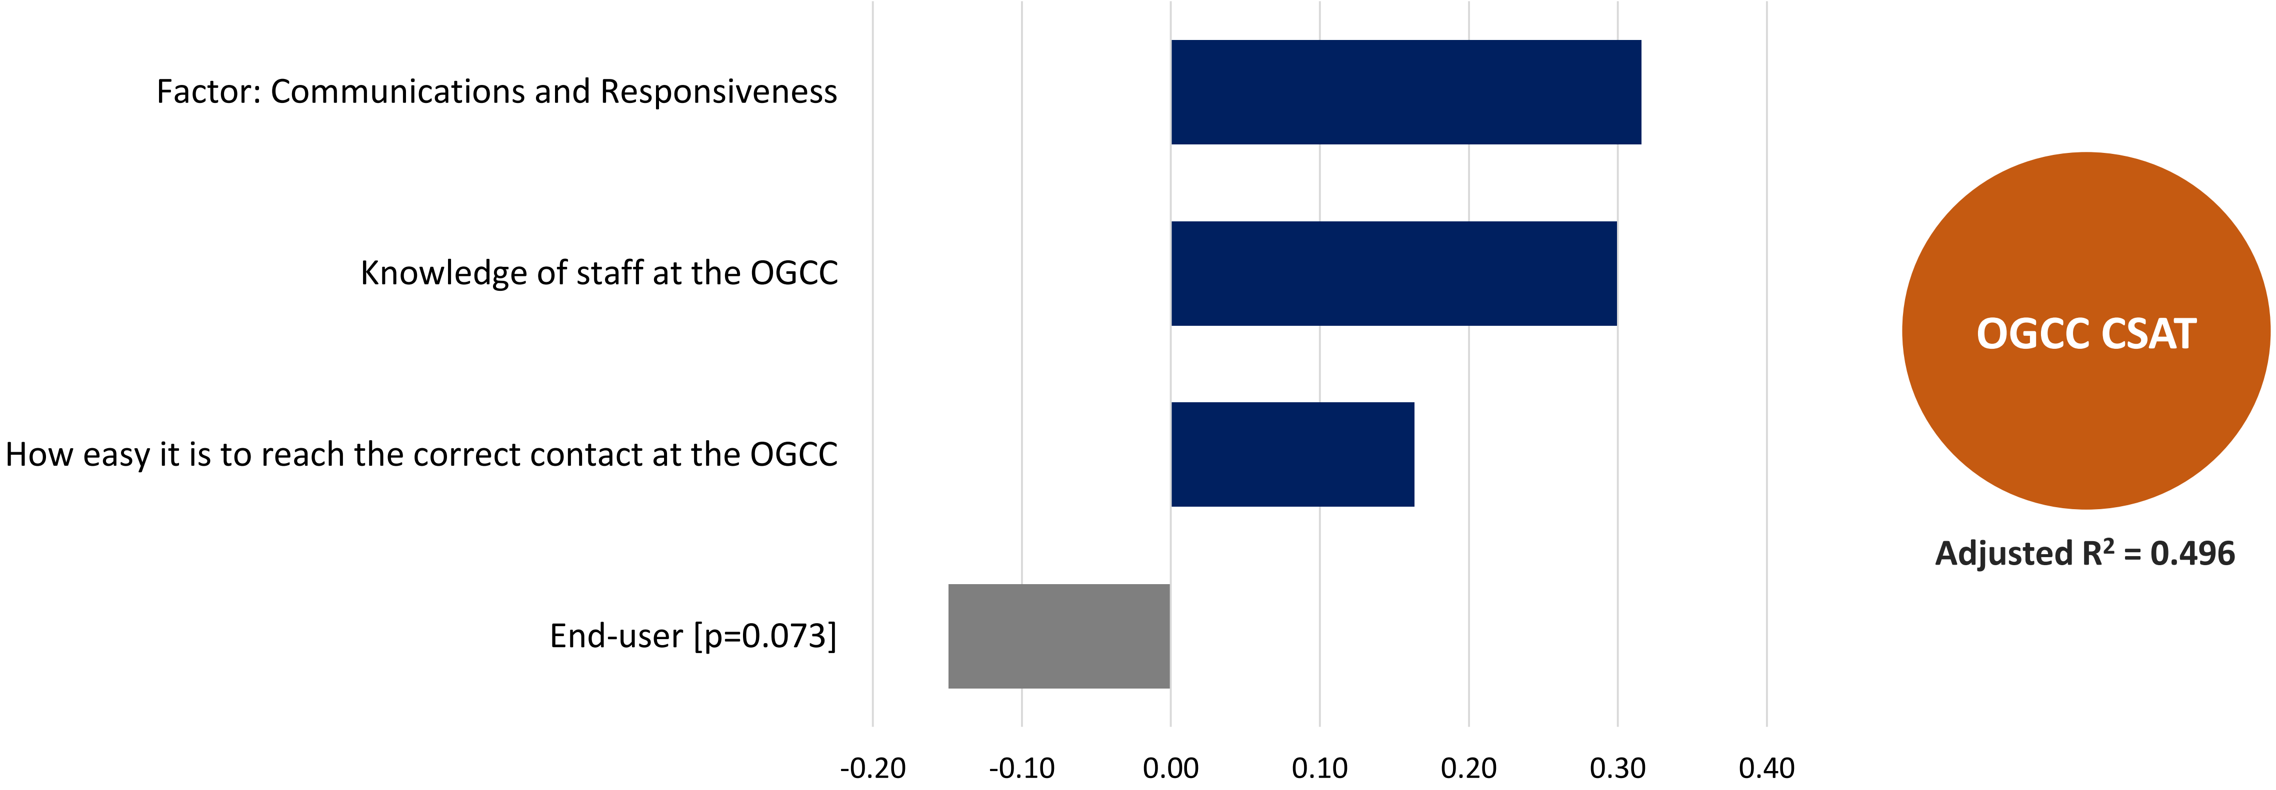
- The OGCC's day-to-day communications with their organization
- The OGCC responds to the needs of their organization in a timely manner

Factor: Communications and Responsiveness

- Knowledge of staff at the OGCC
- How easy it is to reach the correct contact at the OGCC

Regression Analysis: *Identifying drivers of customer satisfaction*

The strongest driver of customer satisfaction is *Communications and Responsiveness*. Many aspects of OGCC, such as knowledge of staff and the ease of reaching the correct contact, also have statistically significant impacts on customer satisfaction.



NOTES: Factor ***Communications and Responsiveness*** combines "the OGCC's day-to-day communications with their organization" and "the OGCC responds to the needs of their organization in a timely manner".
Chart shows standardized beta scores. All drivers significant at a 95% confidence interval unless indicated otherwise.

1.4 (5.2.3, 2.4.3) PERFORMANCE MEASUREMENT FOR CONTINUOUS IMPROVEMENT: BENCHMARKING AND OTHER STUDIES

Benchmarking studies and third party assessments help inform Hydro One of the condition of its assets and how to effectively and efficiently manage those assets. To support this Application, Hydro One has commissioned the following third-party studies:

- Results of PTX Analysis of Hydro One's Transformer Fleet;
- Derivation of Transmission Substation Transformer Hazard Functions;
- Derivation of Circuit Breaker Hazard Functions;
- Derivation of Overhead Conductor Hazard Function;
- Operating Spare Transformers Requirement Assessment;
- Expected Service Life Survey of Transformers and Circuit Breakers;
- Expected Service Life Assessment of Specific Relays;
- Expected Service Life Assessment of Specific Underground Transmission Cables;
- Review of Utilities' Management of Air Blast Circuit Breakers;
- Review of Utilities' Management of Oil Circuit Breakers;
- Degradation Rates of Steel Tower Coating Systems;
- Polymer Insulator Population Assessment;
- Phase 2: Canadian Porcelain/Canadian Ohio Brass Porcelain Insulator Population Assessment;
- Review of Hydro One's Capabilities in Transmission Asset Analytics and Reliability Risk Modelling;
- Investment Planning Process Review;
- Line Loss Assessment;
- Total Factor Productivity and Econometric Total Cost Benchmarking Study; and
- Compensation Cost Benchmarking Study.

The first fifteen of the above-listed third-party studies are discussed in TSP Section 1.4.2, below. The remaining three third party studies correspond to other aspects of the Application and are discussed elsewhere, as indicated below:

- The Line Loss Assessment is discussed in TSP Section 1.8;
- The Total Factor Productivity Study and Econometric Total Cost Benchmarking Study is discussed in Exhibit A, Tab 4, Schedule 1; and
- The Compensation Cost Benchmarking Study is discussed in Exhibit F, Tab 4, Schedule 1.

1.4.1 (5.3.2 C, 2.4.3) BENCHMARKING OVERVIEW

Hydro One's Application and transmission system plan are supported by benchmarking reports prepared by independent consultants. This section provides background on the consultants. Summaries of the studies, including their purpose, methodology, findings and significance for Hydro One's capital expenditure plan and its Application are included in Section 1.4.2 of this Exhibit. Summaries of the technical findings of the studies are provided in Section 1.4.3 and copies of the studies are included as Attachments in Section 1.4.4. The focus is on benchmarking and other studies related to asset condition and asset management.

1.4.1.1 BENCHMARKING AND OTHER STUDY CONSULTANTS

Electric Power Research Institute ("EPRI"), Kinectrics, Metsco Energy Solutions Inc. ("Metsco"), and the Boston Consulting Group ("BCG") assisted with Hydro One's benchmarking and asset condition and management process objectives as described herein.

Electric Power Research Institute

EPRI is an independent, non-profit organization that researches electricity generation, delivery and utilization to enhance quality of life by making electric power safe, reliable, affordable, and environmentally responsible. EPRI was originally created as a result of the Great North Eastern Blackout in November 1965 that left 30 million people in the United States without power. EPRI has established a strong reputation within the energy sector as a leading research and development organization that provides thought leadership, industry expertise, and collaborative value to help the electricity sector identify issues, technology gaps, and broader needs that can be addressed through effective research and development programs for the benefit of society. Its membership represents approximately 90% of the electric utility revenue generated in the United States and extends to participation in more than thirty five countries.

Kinectrics

Kinectrics is an independent testing, inspection, certification and consulting company based in Toronto. Kinectrics focuses on the development and application of advanced technologies for the power industry. Kinectrics serves the energy sectors in Canada, the United States and internationally, with twenty five unique laboratory and testing facilities, expertise built on over 100 years of experience, and over 400 engineers and technical experts.

Metsco Energy Solutions Inc.

Metsco is a Canadian corporation that has provided services to international electric utility clients focused on improving operating efficiency, financial performance and power system asset management since 2006. Metsco has experience in fields such as asset data analysis, failure curves, reliability analysis and reliability projections which has allowed them to become well-versed with the various methodologies, challenges, and strengths that exist in the industry. They have worked on developing health index formulations for the Centre for Energy Advancement through Technological Innovation to connect health indices to failure probabilities and risk assessment to drive investment decisions. Metsco's experts are recognized pioneers in the field of asset management, having been part of the founding committee of the health index methodology for asset risk assessment.

Boston Consulting Group

The Boston Consulting Group ("BCG") provides analysis of process management, capital planning, and the utility industry. BCG is a leading global consulting firm with over 14,000 employees and 90 offices in 50 countries. BCG has completed more than 2,500 energy cases in the past five years and has worked with fifteen of the twenty-five largest global utilities. Senior BCG leadership with extensive experience in utility operations, utility capital planning, and large capital project management globally and in Canada conducted the review of in support of this Application. The team also consisted of executing team members with significant experience in regulated utility operations and regulatory strategy in the US and Canada, including in Ontario.

EPRI, Kinectrics, Metsco, and BCG are reputable organizations with established track records of producing high quality, fact-based, technical deliverables. This is the reason why Hydro One had chosen them to perform the benchmarking and other studies described below.

1.4.2 (5.3.2 C, 2.4.3) SUMMARY OF BENCHMARKING AND OTHER STUDIES

In its Decision and Order in Hydro One's EB-2016-0160 proceeding, the OEB found that "Some of the elements that require more focus include a consistent, comprehensive asset condition assessment process which directly links to the Transmission System Plan ("TSP") and the capital investment plan; an appropriate pacing of capital expenditures that achieves a proper balance of need and rate impact." Hydro One engaged third party experts to perform a series of studies and reviews on specific assets and their treatment to determine whether Hydro One is following industry best practices for condition assessments, asset management and capital expenditure pacing. Hydro One is using the findings and recommendations from these studies to improve its processes.

The benchmarking and other studies described below demonstrate that Hydro One's practices and processes for managing its key transmission assets are aligned with industry best practices. In two areas; underground cables and overhead conductor, the study results recommended Hydro One increase its expected service life ("ESL") for these assets. Hydro One will review its management practices and decision making procedures to minimize life-cycle costs and more effectively manage risk for these assets based on these recommendations. However, as asset replacements in Hydro One's business plan are selected based on end of life of the asset, this has not impacted the current business plan.

BCG's Investment Plan Process Review results confirm that overall, Hydro One has implemented a consistent, thorough planning process that meets or exceeds expectations for a typical utility planning process in all areas. Metsco found that across the categories of their assessment, and in consideration of their utilization relative to other analytical and diagnostic tools comprising Hydro One's process, both Asset Risk Assessment ("ARA") and Asset Analytics ("AA"), are comparable to other asset management frameworks found elsewhere in the industry, and are sufficiently rigorous and robust to accomplish their intended tasks from an analytical perspective. Both ARA and AA are predominantly in line with advanced industry practices, with certain analytical elements approaching best-in-class capabilities.

Metsco reviewed the Reliability Risk Model ("RRM") and found that the analytical underpinnings and functionalities of the RRM trail advanced industry system reliability practices where used in asset management. In making this observation, Mestco found that a number of utilities do not nor have not until recently attempted to formally forecast system reliability in a comprehensive manner and suggests the RRM reflects continuous improvement in this area. However, as Hydro One uses the RRM as a customer communications tool to convey directional changes to reliability risk levels across spend scenarios, Metsco is of the view that the observed gaps pose no meaningful risks from an asset planning perspective. Hydro One must remain clear about the tool's purpose and the implications of its analysis.

The overall results of these studies demonstrate that Hydro One optimizes the life cycles of its assets and selects the appropriate assets for replacement in the Business Plan. This shows that Hydro One is well positioned to provide value to customers.

The technical findings from the studies are provided in Section 1.4.3, below. TSP Section 3.2.4 describes how Hydro One's proposed capital expenditure plan reflects the results of these studies/assessments.

1.4.2.1 RESULTS OF PTX ANALYSIS OF HYDRO ONE'S TRANSFORMER FLEET

Assessing the condition of in-service equipment accurately and efficiently is a critical step in asset management. In the context of a transmission system, there is no equipment for which this is more important than power transformers. Hydro One engaged EPRI to assess the condition of its transformers using the PTX analysis program. EPRI developed the PTX methodology for assessing the condition of transformers by analyzing dissolved gas data from a utility's historical oil data records. PTX identifies transformers with abnormal test results that are then subject to further consideration as to whether more detailed testing or increased monitoring is warranted. The resulting report from EPRI provides an overview of the PTX methodology and presents the results of its analysis for those of Hydro One's transmission system transformers for which data was provided.

In the report, the results are classified by primary voltage class and vintage and have been categorized into five condition risk rankings.

The results obtained by EPRI using its PTX tool are closely aligned with the results of the condition assessment methodology that Hydro One currently uses. This confirms that Hydro One's transformer condition assessment practices are aligned with industry best practices. More particularly, 80.5% of the asset condition assessments for Hydro One's transmission transformer fleet aligned with EPRI's PTX analysis based on dissolved gas in oil content and oil quality data. For the remaining 19.5% of assessments, the results of which were not well aligned, the majority of the differences are attributed to data issues such as oil cross contamination between tap changer and main tank oil. Hydro One depends on the subject matter experts to account for these issues. Therefore, Hydro One will continue its current practices and will track and monitor future test results.

1.4.2.2 DERIVATION OF TRANSMISSION SUBSTATION TRANSFORMER HAZARD FUNCTIONS

While Hydro One focuses on asset health including factors such as condition, criticality, reliability, and cost for asset replacement decisions, the mean life expectancy of equipment fleet is a key requirement for long term planning. It informs resourcing requirements, outage coordination, rate impact, and long term project schedules from planning to execution of work. Insights on fleet mean life expectancy may be derived from careful analysis of historical replacement data. The report arising from this study describes EPRI's efforts to model and develop transformer removal rates from historical replacement records and apply them to forecast the number of transformers expected to require replacement based on past practices. The purpose of the study is to develop transformer removal rates from historical replacement records and apply them to forecast the number of transformers expected to require replacement based on past practices.

Using Hydro One's transformer retirement data, EPRI modeled the transformer removal functions and has forecasted probable transformer replacement rates for the next 5 years.

This study confirms that Hydro One's pacing of transformer replacements is aligned with EPRI's forecast based on industry best practices. Hydro One will therefore continue its current pacing forecast to sustain its transformer fleet.

1.4.2.3 DERIVATION OF CIRCUIT BREAKER HAZARD FUNCTIONS

This report describes EPRI's efforts to model and develop circuit breaker removal rates from historical replacement records and apply them to forecast the number of circuit breakers expected to require replacement based on past practices.

EPRI has developed a methodology using advanced statistical techniques for analyzing circuit breaker (of all types) historical removals and applied it to Hydro One's circuit breaker fleet. Using Hydro One's circuit breaker retirement data, EPRI modeled Hydro One's circuit breaker removals and has forecast probable future removal rates.

This study confirms that Hydro One is replacing younger power circuit breakers at a rate expected from the Weibull model due to failures. However, older vintages of circuit breakers are being replaced at a quicker rate than expected.

Hydro One's volume of replacement over the plan period is higher primarily due replacement criteria that were not included in the EPRI report. These criteria include obsolescence concerns, safety concerns (e.g. lack of or insufficient arc resistance rating), change in system conditions (e.g. short circuit level), polychlorinated biphenyl ("PCB") mitigation per regulatory requirements and integrated investments. Further details on the reasons can be found in Section 3.2.4 of the TSP.

1.4.2.4 DERIVATION OF OVERHEAD CONDUCTOR HAZARD FUNCTION

This report describes EPRI's efforts to develop a conductor hazard curve and its ESL which can be used to project expected replacement needs for planning purposes.

The results of this study based on current condition assessment data and historical overhead conductor replacement data, indicate that ESL for overhead conductors in the Hydro One transmission system should be approximately 90 years. Hydro One's assigned ESL for overhead conductors was set at 70 years before this study. The new ESL resulting from this study does not affect the current business plan as identified replacements are not age based decisions, they are based on verified asset condition..

1.4.2.5 OPERATING SPARE TRANSFORMERS REQUIREMENT ASSESSMENT

The purpose of this study is to verify that Hydro One's spare transformer requirements are appropriate and consistent with industry best practices. Hydro One uses the Markov Model to determine the appropriate number of spare transformers required to ensure continuity of electricity supply to customers, safety and reliability. The Markov Model takes into consideration the probability of failure, carrying costs and procurement lead time to determine the most cost-effective number of spares to be kept in inventory. EPRI has developed analytics to optimize the power transformer spares practice which was compared with Hydro One Markov modeling.

This study confirms that Hydro One’s Operating Spare Transformer Strategy aligns with industry best practices. Hydro One will continue these practices and will continue to monitor the spare transformer inventory periodically to maintain the inventory at an adequate level. Therefore, there is no impact to the current investment plan for the TSP planning period (2020 to 2024).

1.4.2.6 ESL SURVEY OF TRANSFORMERS AND CIRCUIT BREAKERS

Utilities face a growing challenge to reduce operating and maintenance costs without adversely affecting service levels or investment requirements. EPRI designed two surveys to acquire information and insights on industry attitudes and practices related to asset management of transmission circuit breakers and transformers. This survey pools a number of electrical utilities (27 respondents for breakers and 35 respondents for transformers from across North America) to assess whether Hydro One’s current ESLs for transformers and circuit breakers are aligned with industry best practices. Hydro One uses ESL as a screening factor to assess investment need and pacing. The ESL is used as a trigger for a more in depth investigation through detailed asset condition assessment.

Transformers

EPRI’s transformer survey found that the ESL used within Hydro One for transformers is closely aligned with industry consensus. Moving forward, Hydro One will continue to stay current with industry best practices with respect to setting ESL for transformers.

The survey also found that Hydro One’s transformer replacement and assessment practice is similar to the majority of respondents, including target replacements based upon assessment of the asset using test and inspection results. The majority of utilities have a formal process and algorithm for assessing transformer condition with,75% of these utilities use a risk-based approach with condition and system criticality ranking highest for their algorithm inputs. Like Hydro One, most utilities do not allow the algorithm to trigger a replacement but also rely on the input of subject matter expert assessments.

Circuit Breakers

With respect to circuit breakers, EPRI found that Hydro One's ESL for the various types of circuit breakers in the transmission system are aligned with industry best practices as indicated by the survey results. Hydro One will therefore continue to pace the rate of replacements in accordance with its current practice. Hydro One will monitor this pace and adjust as required if information or trending dictates otherwise.

The circuit breaker survey also indicated that Hydro One was one of the few utilities to have a formal circuit breaker condition algorithm and/or process for assessing circuit breaker condition. Like Hydro One, most of the utilities that have such a process do not allow automatic replacement based only on the algorithm but also rely on subject matter expert assessments. The majority of respondent utilities replace circuit breakers by type/family regardless of individual age or condition with decisions highly based on population condition, ownership costs, reliability, safety, and environmental impact.

1.4.2.7 ESL ASSESSMENT OF SPECIFIC RELAYS

Hydro One's protective relay fleet consists of three technologies: electromechanical, solid state, and microprocessor. Electromechanical relays have the longest ESL and have very reliable performance. At the time of the report, solid state relays account for 58% of all relays currently operating beyond ESL, which is a risk to safety and reliability as shown in TSP Section 2.2.1.3. Microprocessor based relays (IEDs) now represent 52% of the total installed base. Specific microprocessor relays have performed poorly, leading Hydro One to question the validity of the 20-year ESL. As a result, Hydro One hired Kinectrics to quantify the risk associated with solid state and microprocessor relays and to advise on the appropriate pacing for replacement.

The Kinectrics report identified that Hydro One's ESL range is above the industry range of 13 to 19 years for solid-state relays and in-line with the range of 13 to 20 years for microprocessor relays. The study identified the possibility of increasing ESL for the examined solid-state and microprocessor relay models, but did not offer further guidance as to the appropriate level.

Relay replacements are selected based on various criteria and not solely dependent on ESL, as described in TSP Section 2.2. Hydro One will review its current practices and decision making process as well as continue to track and monitor the performance of its relays, based on the report's recommendations, to maximize the utilization of the relay fleet while managing its associated risk.

1.4.2.8 ESL ASSESSMENT OF SPECIFIC UNDERGROUND TRANSMISSION CABLES

Hydro One makes asset replacement decisions based on detailed condition assessments that verify whether an asset has reached its end of life. In this context, ESL is used as a screening factor and acts as a population health assessment metric. Based on the original design criteria, Hydro One is using 50 years as the ESL for its underground cables. However, operating experience within Hydro One and other utilities is suggesting an ESL of more than 50 years for low-pressure and high-pressure liquid-filled cables may be more appropriate. This study was carried out to determine the suitable ESL based on technical and engineering principles, condition assessment and operating experience.

EPRI has determined due to the current loading on Hydro One's low-pressure and high-pressure liquid-filled (LPLF and HPLF) cables that the suitable ESL should be increased to 70 years. Hydro One has previously been using 50 years as the ESL for these assets. The ESL is not used to trigger replacement. Replacement is triggered by asset condition. As the cable replacements planned for the 2020 to 2024 planning period of this rate application are based on the end of life condition of these cables, no changes will be made to the current investment plan. Hydro One has incorporated EPRI's recommendation and study findings into its cable asset strategy.

1.4.2.9 REVIEW OF UTILITIES' MANAGEMENT OF AIR BLAST CIRCUIT BREAKERS

This is a survey of industry best practices on the effective management of Air Blast Circuit Breakers ("ABCBs"). The industry in general is phasing out ABCBs due to poor performance, high maintenance costs and technological obsolescence. This survey has reviewed industry experience and assessed attitudes, experience and practices related to ABCBs to assist Hydro One in understanding how peer companies are responding to similar challenges and inform its own strategies for addressing this class of assets.

The data EPRI collected for this survey has demonstrated that Hydro One's approach to managing ABCBs is consistent with the industry norm. Some survey respondents mentioned they no longer had air blast breakers. EPRI's review found that "The higher cost/difficulty associated with maintenance requirements when compared to newer technology, the unavailability of spare parts due to obsolescence, and the lack of dedicated crews to work on the ever-aging population of installed air blast circuit breakers may lead to longer outage times associated with both routine and emergency maintenance. This could become problematic for utilities and customers on both a cost and service-reliability perspective."

This study confirms that other utilities are also replacing or have already replaced their ABCBs due to poor performance and associated high costs for maintenance. The lack of available spare parts to properly maintain these types of breakers has become problematic for utilities due to the age of the technology and obsolescence. These results confirm that Hydro One is aligned with industry best practices to remove the ABCB fleet from service.

1.4.2.10 REVIEW OF UTILITIES' MANAGEMENT OF OIL CIRCUIT BREAKERS

This is a survey of industry best practices on the effective management of Oil Circuit Breakers ("OCBs"). This survey was conducted to review industry experience, assess practices related to OCBs and to understand how peer companies are responding to similar challenges. High voltage OCBs are an older technology that relies on complex mechanical systems for operation and large amounts of oil for insulation. OCB technology has generally performed well over decades of service. However, due to their age, insufficient ratings and environmental concerns about oil, OCBs may be considered less desirable technology. For these reasons, many utilities have decided to reduce the size of their OCB fleets.

The results of this study confirm that other utilities are also replacing their OCBs due to poor performance and associated high costs for any maintenance. The lack of available spare parts to properly maintain these types of breakers has become problematic for utilities due to the age of the technology and obsolescence. These results confirm that Hydro One is aligned with industry best practices to remove the OCB fleet from service. Hydro One intends to remove these breakers at the pace indicated in the business plan for the test years.

1.4.2.11 DEGRADATION RATES OF STEEL TOWER COATING SYSTEMS

The study results will be used to improve the accuracy and resolution of the Ontario Atmospheric Corrosion Map by performing detailed assessments on 100 steel structures. The findings will be used to identify and optimize Hydro One's steel structure maintenance requirements and enhance its service life extension approach.

This study confirms that the majority of Southern Ontario falls under the C4 corrosion rate category, with small pockets of C5[1] corrosion rate zones. The resolution of the atmospheric corrosion map has been refined with more defined boundaries between the various corrosion zones. This information enables Hydro One to use the higher resolution of the Ontario Atmospheric Corrosion Rate Map to optimize the tower coating program and to maximize the steel tower lifecycle. Hydro One accepts EPRI's recommendation to use the updated Ontario Atmospheric Corrosion Map to make more accurate decisions about the degradation of steel structures throughout the province. Hydro One plans to address these recommendations by overlaying the updated atmospheric corrosion map with existing HONI Geographic Information System ("GIS") data, in order to more accurately assign corrosion zones to each structure.

1.4.2.12 POLYMER INSULATOR POPULATION ASSESSMENT

Hydro One has a large population of 230 kV and 115 kV polymer insulators. Some of these insulators are showing signs of deterioration, which has led to several failures in the past years. Two of these failures have resulted in line drops. Hydro One removed 87 in-service polymer insulators from various configurations within the Hydro One transmission service territory to enable sampling and testing. EPRI performed a detailed assessment of these assets and provided insights into the overall population condition to inform Hydro One's replacement needs.

Based on its assessment of 87 insulators, EPRI found that the condition of polymer insulators currently in-service in Hydro One's transmission system varies based on voltage, manufacturer and use of corona rings. The results of this study have shown that Hydro One should plan to remove specific 230 kV insulators from service as soon as

[1] Based on the ISO 9223, typical atmospheric environments are categorized from C1 through to C5, with C1 exhibiting very low in corrosivity, and C5 exhibiting very high corrosivity.

possible due to immediate or high risk of failure. Other types of 230 kV insulators should continue to be assessed periodically for signs and degree of degradation. EPRI further recommends that linemen should check the integrity of these insulators prior to performing any live maintenance procedures due to potential safety issues. Considering the study results, Hydro One will prioritize the removal of specific polymer insulators in its current replacement program.

1.4.2.13 PHASE 2: CP/COB PORCELAIN INSULATOR POPULATION ASSESSMENT

This is Phase 2 of the 1965 to 1982 vintage Canadian Ohio Brass (COB) and Canadian Porcelain (CP) insulator population condition assessment study. Phase 1 was completed in 2016 and was intended to ascertain the urgency for taking action to ensure safety at publicly accessible locations. Phase 2 required the removal of approximately 600 insulators from service and subjected these samples to more detailed laboratory testing (compared to Phase 1) to further assess their long-term condition and assist Hydro One in prioritizing and pacing future replacements of these assets.

After testing 591 samples, EPRI found overwhelming evidence to support the recommendation that Hydro One should remove the fleet of COB and CP porcelain insulators from service as soon as is practically possible to mitigate the risk to safety and reliability. Based on the results of Phase 2 COB/CP testing, insulators posing a higher public safety risk (i.e. insulators in critical locations) will be replaced by 2022 at a rate of approximately 3,700 circuit structures per year.

1.4.2.14 REVIEW OF HYDRO ONE'S CAPABILITIES IN TRANSMISSION ASSET ANALYTICS AND RELIABILITY RISK MODELLING

Hydro One engaged Metsco to perform a third-party assessment of three elements of its transmission system Asset Management ("AM") process, namely the Asset Analytics ("AA"), Asset Risk Assessment ("ARA") and Reliability Risk Model ("RRM") frameworks. The study reviewed Hydro One's AA and decision-making process, the six criteria, methodology, and data inputs utilized to calculate asset scores, and identified areas for improvement and other recommendations.

Metsco's overall conclusion was that across the categories of assessment, and in consideration of their utilization relative to other analytical and diagnostic tools comprising Hydro One's AM process, both ARA and AA are comparable to other asset management frameworks found elsewhere in the industry, and are sufficiently rigorous and robust to accomplish their intended tasks from the analytical perspective.

With respect to the RRM, Metsco found that the tool's analytical underpinnings and functionalities trail advanced industry system reliability practices where these are deployed. In making this observation, it was noted that a number of transmission utilities do not or have not until recently attempted to formally forecast system reliability in a comprehensive manner. This contextual observation suggests that the RRM capability constitutes a bona fide continuous improvement step – one that poses no meaningful system planning risks given the limited role that it currently plays in the AM process.

This study identifies that although Hydro One has a robust and rigorous process, there is always an opportunity to improve. The recommendations from this review will inform Hydro One's efforts to enhance its processes used to manage its major transmission assets, transformers, breakers and conductors. As part of its commitment to continuous improvement, Hydro One has implemented enhancements to its Asset Analytics investment planning decision support tool in 2018. The enhancements updated the existing algorithms and weighting calculations to improve the quality of the asset risk model to better inform decision making.

1.4.2.15 INVESTMENT PLANNING PROCESS REVIEW

Hydro One engaged BCG to prepare this report in response to the OEB's request for Hydro One to review its investment planning process. To conduct the review, BCG identified a set of capabilities typically required to execute an investment planning process competently. These were drawn from two sources – ISO 55000 asset management standards and industry best practices gathered through interviews with experts and through BCG's experience working with leading utilities globally. Recommendations from BCG for improvements to Hydro One's Asset investment planning process will inform future efforts by Hydro One to improve its planning process.

This study confirms that overall, Hydro One has implemented a consistent, thorough planning process that meets or exceeds expectations for a typical utility planning process in all areas. This information supports Hydro One's submission that the Investment Planning Process is robust and previous issues identified have been addressed. The report also includes recommendations that encourage Hydro One to continue to collect relevant condition data, update strategies, and implement forecasting outcome measures. Hydro One's progress regarding the implementation of these recommendations is provided in Attachment 15 to this Exhibit.

1.4.3 (5.3.2 C, 2.4.3) TECHNICAL FINDINGS FROM BENCHMARKING AND OTHER STUDIES

This section provides additional technical details regarding the key technical findings of each study, survey or assessment to support the high-level discussion in Section 1.4.2.

1.4.3.1 RESULTS OF PTX ANALYSIS OF HYDRO ONE'S TRANSFORMER FLEET

Table 1 - Key Study Findings of PTX Analysis of Hydro One's Transformer Fleet

#	Key Study Findings	Study Reference
1	EPRI's PTX methodology has identified 129 transformers with elevated Normal Degradation Index (NDI) within Hydro One's fleet of transformers	Section 3 (Page 3-1)
2	EPRI's PTX methodology has identified 88 transformers with elevated Abnormal Index that could consist of abnormal thermal, electrical and/or core problems within Hydro One's fleet of transformers	Section 3 (Page 3-1)
3	A single transformer can have multiple indices at elevated levels within a single PTX analysis	Section 3 (Page 3-2)

Table 2 - Recommendations of PTX Analysis of Hydro One's Transformer Fleet

#	Recommendations	Study Reference
1	A transformer with a high abnormal index rating should be assessed / re-assessed in the short term.	Section 2 (Page 2-2)
2	A transformer with a high normal degradation index rating should be assessed for long term needs	Section 2 (Page 2-2)

1.4.3.2 DERIVATION OF TRANSMISSION SUBSTATION TRANSFORMER HAZARD FUNCTIONS

Table 3 - Derivation of Transmission Substation Transformer Hazard Functions Key Study Findings

#	Key Study Findings	Study Reference
1	An updated methodology has been provided by EPRI to use a "prior distribution" to forecast probable number of replacements over a five year time period.	Section 3 (Pages 3-8, 3-17, 3-26, 3-35)
2	Hazard curve function analysis suggests that the removal rate of Hydro One's fleet can be categorized in 2 regions, where Region 1 can closely approximate Hydro One failure rate.	Section 2 (Page 2-6)
3	Hazard curve function analysis suggests that the removal rate in Region 2 is largely due to discretionary removal (planned replacement)	Section 2 (Page 2-6)

1.4.3.3 DERIVATION OF CIRCUIT BREAKER HAZARD FUNCTIONS

Table 4- Derivation of Circuit Breaker Hazard Functions Key Study Findings

#	Key Study Findings	Study Reference
1	Methodology is provided for using a "prior distribution" to forecast probable number of replacements over a five year time period.	Section 3 (Pages 3-9, 3-18, 3-27, 3-36, 3-45, 3-54, 3-63, 3-72, 3-81, 3-90, 3-99, 3-108, 3-117, 3-126)
2	Hazard curve function analysis suggests that the removal rate of Hydro One's fleet can be categorized in 2 regions, where Region 1 can closely approximate Hydro One failure rate.	Section 2 (Page 2-3)
3	Hazard curve function analysis suggests that the removal rate in Region 2 is largely due to discretionary removal (planned replacement)	Section 2 (Page 2-3)

1.4.3.4 DERIVATION OF OVERHEAD CONDUCTOR HAZARD FUNCTION

Table 5 - Derivation of Overhead Conductor Hazard Function Key Study Findings

#	Key Study Findings	Study Reference
1	By applying EPRI's Weibull Hazard model, the ACSR conductor fleet median age for reaching EOL based on existing condition assessment data is about 90 years ("91 years").	Section 4 (Pages 4-3 to 4-4)
2	By applying EPRI's Weibull Hazard model, the ACSR conductor fleet median age for reaching EOL, based on historical conductor replacements is about 90 years ("89.5 years").	Section 4 (Pages 4-3 to 4-5)
3	Based on Key Study Finding #1 above, an additional 2,264 km of conductor is expected to be beyond expected service life by 2024.	Section 5 (Page 5-3)

1.4.3.5 OPERATING SPARE TRANSFORMERS REQUIREMENT ASSESSMENT

Table 6 – Operating Spare Transformer Requirement Assessment Key Findings

#	Key Study Findings	Study Reference
1	EPRI's independent analysis to determine the appropriate number of Operating Spare Transformers aligns with Hydro One's inventory.	Table 4-1 (Page 71)

1.4.3.6 ESL SURVEY OF TRANSFORMERS AND CIRCUIT BREAKERS

Table 7 – Transformer Key Survey Findings

#	Key Findings	Report Reference
1	Around three-quarters of respondents used some formal definition of End of Life	Section 8 (Page 8-1)
2	Majority of participants expressed concerns when power transformer operates beyond 50 years.	Section 8 (Page 8-2)
3	Majority of participants target replacements based upon assessment of the asset using test and inspection data.	Section 8 (Page 8-3)
4	Just over 50% of utilities budget for a specified number of replacements per year with the highest weights on condition of individual asset and budgetary constraints	Section 8 (Page 8-3)
5	Half of utilities refurbish transformers to extend life	Section 8 (Page 8-3)

#	Key Findings	Report Reference
6	Majority of utilities do have a formal process or algorithm for assessing transformer condition. Nearly 75% of utilities use a risk-based approach with condition and system criticality ranking highest for their algorithm inputs	Section 8 (Page 8-3)
7	Most utilities that have a formal process or algorithm for assessing transformer condition do not allow the algorithm to automatically trigger a replacement	Section 8 (Page 8-3)

Table 8 – Circuit Breaker Key Survey Findings

#	Key Findings	Report Reference
1	Majority of respondents get concerned about breaker based on age beginning at approximately 44 years of age.	Section 8 (Pages 8-1 to 8-2)
2	Two-thirds of respondents do not run transmission circuit breakers to failure	Section 8 (Page 8-2)
3	Condition and safety are the two highest ranked criteria by respondents for replacing a breaker	Section 8 (Page 8-2)
4	Majority of utilities do not have a formal process or algorithm for assessing circuit breaker condition	Section 8 (Page 8-2)
5	Most utilities that have a formal process or algorithm for assessing circuit breaker condition do not allow the algorithm to automatically trigger a replacement	Section 8 (Page 8-2)
6	Majority of utilities do replace circuit breakers by type/family regardless of individual age or condition with decisions highly based on population condition, population ownership costs, population reliability, safety, and environmental impact.	Section 8 (Page 8-2)

1.4.3.7 ESL ASSESSMENT OF SPECIFIC RELAYS

Table 9 - ESL Assessment of Specific Relays Key Study Findings

#	Key Study Findings	Study Reference
1	MCGG 22 relays: six out of the nine component categories, or 67%, exceeded 25 years by the end of the test. For the remaining three component categories many more months of heat-soaking would be required to age these to 25 years.	Page 25
2	D60 relays: nine out of the 12 component categories, or 75%, exceeded 20 years by the end of the test. For the remaining three component categories, many more months of heat-soaking would be required to age these to 25 years.	Page 27

Table 10 - ESL Assessment of Specific Relays Recommendations

#	Recommendations	Study Reference
1	Review the deemed ESL values of 25 and 20 years respectively for the MCGG 22 and D60 relays.	Page 32
2	Continue heat-soak testing of both MCGG 22 and D60 relays for demonstrating the set reliability target pertaining to resistors, relays (miniature) and inductors/transformers/chokes.	Page 33

1.4.3.8 ESL ASSESSMENT OF SPECIFIC UNDERGROUND TRANSMISSION CABLES

Table 11 – ESL Assessment of Specific Underground Cables Key Study Findings

#	Key Study Findings	Study Reference
1	Both LPLF and HPLF cables have been operated below their thermal limits resulting in minimal thermal insulation degradation.	Section 3 (Page 12 & 15)

Table 12 – ESL Assessment of Specific Underground Transmission Cables Recommendations

#	Recommendations	Study Reference
1	The ESL of both LPLF and HPLF cables can be increased to 70 years.	Section 6 (Page 26)
2	Hydro One should continue its maintenance and testing program.	Section 6 (Page 26)
3	Cable condition will be evaluated in detail five years prior to it reaching its ESL to determine if additional maintenance or replacement is required.	Section 6 (Page 26)

1.4.3.9 REVIEW OF UTILITIES' MANAGEMENT OF AIR BLAST CIRCUIT BREAKERS

Table 13 - Review of Utilities' Management of Air Blast Circuit Breakers Key Findings

#	Key Study Findings	Study Reference
1	Air blast circuit breakers are "more" to "much more costly/difficult" to perform both minor and major maintenance	Section 4 (Page 4-1)
2	ABCBs are "less" to "much less reliable" when compared to single pressure gas breakers.	Section 4 (Page 4-1)
3	Principal drivers behind programmatic replacement were operation and maintenance costs and an unacceptable level of reliability/availability.	Section 4 (Page 4-1)
4	The population of ABCBs for utilities has been reduced by two-thirds over the last decade with no new ABCBs being installed.	Section 4 (Page 4-1)
5	The lack of available spare parts to properly maintain these types of breakers has become problematic for utilities due to the age of the technology and obsolescence.	Section 4 (Page 4-1)

1.4.3.10 REVIEW OF UTILITIES' MANAGEMENT OF OIL CIRCUIT BREAKERS

Table 14 - Review of Utilities' Management of Oil Circuit Breakers Key Findings

#	Key Findings	Report Reference
1	Utility experience with OCBs is that these types of breakers are somewhat "more costly/difficult" on which to perform both minor and major maintenance.	Page 4-1

#	Key Findings	Report Reference
2	OCBs are somewhat "less reliable" when compared to single pressure gas breakers.	Page 4-1
3	Principal drivers behind programmatic replacement are unacceptable reliability/availability and insufficient ratings for below 138 kV and excessive costs, environmental, and other for above 138 kV.	Page 4-1
4	The population of OCBs for utilities has been reduced by approximately 18% over the last decade.	Page 4-1
5	Nearly 85% of OCBs that are currently installed are over 40 years of age.	Page 4-1
6	Utilities have diminished abilities to properly maintain oil circuit breakers. None of the utility respondents have dedicated crews to perform internal inspections/refurbishments or dedicated shops and/or dedicated contractors to maintain/overhaul oil circuit breakers.	Page 4-1
7	The higher cost/difficulty associated with maintenance requirements when compared to newer technology and the lack of dedicated crews to work on the ever-aging population of installed oil circuit breakers may lead to longer outage times associated with both routine and emergency maintenance.	Page 4-1

1.4.3.11 DEGRADATION RATES OF STEEL TOWER COATING SYSTEMS

Table 15 - Steel Tower Coating Systems Key Study Findings

#	Key Study Findings	Study Reference
1	The resolution of the corrosion rate map has been refined using 2017 field survey data and steel coupons.	Section 5 (Pages 25-27)
2	The majority of Southern Ontario falls under the C4 corrosion rate category, with small pockets of C5 corrosion rate zones.	Section 5 (Pages 25-27)

Table 16 - Steel Tower Coating Systems Recommendations

#	Recommendations	Study Reference
1	Use the Ontario Atmospheric Corrosion Map to make more accurate decisions about the degradation of steel structures throughout the province.	Section 5 (Pages 25-27)

#	Recommendations	Study Reference
2	Additional field surveys and deployment of additional steel coupons will increase the resolution of the maps and reduce the margin of error in structure selection.	Section 6 (Page 29)

1.4.3.12 POLYMER INSULATOR POPULATION ASSESSMENT

Table 17 - Polymer Insulator Population Assessment Key Study Findings

#	Key Study Findings	Study Reference
1	The 230 kV K-Line insulators with the 4-inch donut corona ring have an extremely high likelihood of electrical and or mechanical failure due inadequate control of the electric field on the surface of the rubber housing at the line end. The rubber housing at the line end of these insulators has been severely eroded leading to exposure of the fiberglass rod. Such exposure of the rod will result in either mechanical or electrical failure with a high probability of the insulator parting and causing a conductor drop.	Section 5 (Page 5-1)
2	The 230 kV NGK insulators installed without corona rings are showing signs of serious deterioration of the line-end rubber housing and deterioration of the secondary seal. As such, they are considered to have a high risk of failure.	Section 5 (Page 5-1)
3	The 230 kV NGK insulators installed with 8-inch corona rings are undergoing rubber housing damage at the line end due to the poor design of the mounting portion of the ring. Currently this deterioration does not appear overly serious, but it is not known how quickly the housing deterioration will progress. In the EPRI aging chamber and at one EPRI member utility site this deterioration did result in eventual failure.	Section 5 (Page 5-1)
4	The 230 kV Ohio Brass insulators installed without corona rings are showing rubber and seal deterioration at their line-end fittings. However, in EPRI's experience, the risk of failure can be significantly mitigated by retrofitting corona rings.	Section 5 (Page 5-1)
5	The 230 kV Sediver insulators (all equipped with 11-inch corona rings) are not showing any significant external deterioration	Section 5 (Page 5-1)
6	The 230 kV K-Line insulators installed with 8-inch corona rings do not show any significant signs of deterioration.	Section 5 (Page 5-1)
7	The 115 kV K-Line dead-end insulators do not show any significant visually observable ageing even though they have been in service for 27 years,	Section 5 (Page 5-1)
8	The silicone insulators which have not been damaged due to excessive fields on the rubber surface remain hydrophobic.	Section 5 (Page 5-1)
9	The non-silicone insulators show, as expected, a low degree of hydrophobicity.	Section 5 (Page 5-1)

#	Key Study Findings	Study Reference
10	Each of the insulator groups with the exception of the Ohio Brass insulators had a single insulator unable to meet the dye penetration test requirements.	Section 5 (Page 5-1)
11	Seven 230 kV K-Line insulators exhibited low resistance along their length after humidity conditioning. Of these seven, three had damage from power arcs and housing erosion which may explain their failure. The remaining four (all of which had 8-inch corona rings) will be further examined to determine the root cause of failure.	Section 5 (Page 5-2)
12	All but three insulators passed the test. Of the failing three units, two have been in service for 26 and 27 years, and the third had major line-end rubber erosion and rod exposure.	Section 5 (Page 5-2)

1 **Table 18 - Polymer Insulator Population Assessment Recommendations**

#	Recommendations	Study Reference
1	All 230 kV K-Line insulators fitted with 4-inch donut corona rings should be removed from service as soon as possible since they pose a proven risk of immediate failure.	Section 6 (Page 6-1)
2	All the 230 kV NGK insulators installed without corona rings should be removed from service as they are considered to be at high risk of failure.	Section 6 (Page 6-1)
3	All the 230 kV Ohio Brass insulators installed without corona rings should be removed from service.	Section 6 (Page 6-1)
4	The 230 kV NGK insulators fitted with 8-inch corona rings should be monitored for continuing degradation by removing samples periodically for inspection.	Section 6 (Page 6-1)
5	The seven 230 kV K-Line insulators which failed the water vapor ingress test should be subjected to additional testing followed by dissection to quantify the degree of concern which should be associated with their failing the water vapor ingress test. This type of issue is generally associated with poor bonding between the housing and the rod and is often a batch problem. Until the issue is understood, these insulators should not be maintained live without first checking their integrity with the EPRI developed insulator tester.	Section 6 (Page 6-1)

1.4.3.13 PHASE 2: CP/COB PORCELAIN INSULATOR POPULATION ASSESSMENT

Table 19 - Phase 2: CP/COB Porcelain Insulator Population Assessment Key Findings

#	Key Study Findings	Study Reference
1	A large number of the tested insulators at various ratings exhibited porcelain cracking after M&E testing. As an example, 23% of 59 insulator units with 50 kip rating failed M&E test.	Section 3 (Page3-10)
2	54% of 246 insulator units punctured (cracked) during thermo mechanical cycling (TMC) test based on table 3-8	Section 3 (Page 3-12)
3	The fact that the insulators are highly susceptible to electrical puncture under steep transient voltages due to lightning	Section 5 (Page 5-3)
4	The finding that TMC drastically decreases the already weak ability of the insulators to withstand electrical puncture	Section 3 (Page 5-3)
5	The fact that a significant number of insulators separated mechanically during the TMC.	Section 3 (Page 5-3)

Table 20 - Phase 2: CP/COB Porcelain Insulator Population Assessment Recommendations

#	Recommendations	Study Reference
	The analysis of testing performed on the 591 insulators removed from service in 2017 provides overwhelming evidence supporting replacement to mitigate the risk to the safety and reliability of Hydro One's transmission system. The key recommendation of this work is that the identified population of COB and CP insulators be removed from service as soon as practically possible.	Section 6 (Page 6-1)

1.4.3.14 REVIEW OF HYDRO ONE'S CAPABILITIES IN TRANSMISSION ASSET ANALYTICS AND RELIABILITY RISK MODELLING

Table 21 - Review of Asset Analytics Methodology Recommendations

#	Recommendations	Study Reference
1	Consider clearly separating the risk factors/criteria in AA to (a) define probability of failure of a specific asset, and (b) incorporate the impact of asset failure to explicitly assess a broader variety of outage consequence costs, such as utility's and socioeconomic costs, including the costs associated with the environment, safety/collateral damages, environment, customer interruption costs and financial impacts. Given that many of these additional factors proposed for incorporation into AA are already considered in the subsequent ARA analysis, we qualify this recommendation by stating that HONI may wish to consider it at a juncture where a broader AM process reorganization may be contemplated.	Page 98
2	Re-visit the formulation of its present AA framework and consider potential regrouping / renaming of assessment factors components to better align it with commonly understood industry terminology (such as condition assessment/health index, or impact assessment/consequence cost), and take steps to develop more comprehensive explanatory manuals for its AA capabilities.	Page 98
3	Continue ongoing work to rectify data completeness gaps identified across the individual risk sub-categories for each asset class in Section 3.2, aiming for the highest practicable scores within the resource availabilities, and prioritizing the categories seen as most impactful in light of the criteria weightings.	Page 98
4	Consider supplementing the current condition parameters tracked for each major asset class with additional parameters tracked in the industry, as identified in the appropriate subsections of Section 3.2. As with all input enhancements, evaluate the incremental value proposition of additional parameters relative to the implementation costs by way of financial value for money analysis.	Page 98
5	Consider integration socio-economic factors, including costs to the customer (customer interruption costs), as well as environmental and safety-related monetary cost factors, such that the full range of economic costs (including those that go beyond those incurred by a utility or its customers) can be utilized as part of this evaluation procedure.	Page 98
6	Consider supplementing the obsolescence-based intervention assessments for Protection, Control, and Telecom assets by formally incorporating the results of manual SME activities that already occur in a less formalized manner.	Page 99

1 **Table 22 - Review of Reliability Risk Forecasting Methodology Recommendations**

#	Recommendations	Study Reference
1	Prior to investing any incremental resources into potential refinements, we encourage Hydro One's management to fully articulate a vision of the tool's ultimate place within its asset management and capital planning hierarchy, including whether such a tool is ultimately needed in light of all other capabilities. Subject to the outcome of deliberations suggested in the above recommendation, consider further enhancements to reliability forecasting through an RRM, or an alternative solution.	Page 99
2	Enhance reliability forecasting to assess reliability performance of the transmission system through a variety of reliability indices, rather than rely on the reliability risk modeling.	Page 99
3	Integrate the enhanced reliability forecasting solution into the overall asset management process to provide the asset managers with a more robust set of reliability outcome predictions based on a variety of investment scenarios under consideration.	Page 99
4	Include additional asset classes into the reliability forecasting approach (e.g. tower structures, insulators, switches) and sub-classes to improve the precision level of equipment related risk forecasting.	Page 99
5	Develop a capability to provide reliability risk prediction on a sub-system level, such as system regions or large customer groups.	Page 99
6	Expand the overall approach to reliability / reliability risk forecasting to factor in non-equipment related outages (e.g. weather events, adverse environment, human related errors, foreign interference, etc.) to forecast the reliability risks of the transmission system as a whole.	Page 99
7	Assess the reliability impact of the non-renewal projects in the enhanced reliability forecasting solution. If the utility does not have any such projects in the investment plan, than the benefits of this recommendation are not expected to outweigh the costs of developing this capability.	Page 99
8	Extend the reliability forecasting horizon to at least ten years to capture a greater extent of the long-lasting renewal and non-renewal projects within the investment scenarios on the system reliability.	Page 100
9	Enhance the algorithms utilized to calculate the age demographic profile for each asset class, by revisiting the priority of asset replacements and considering both reactive and inspection-determined failure modes of assets reaching their ends of lives.	Page 100
10	Revise asset class weights or the algorithms that calculate the reliability risk of three key asset classes per each investment scenario to incorporate more asset-specific failure considerations.	Page 100
11	Utilize a variety of econometric techniques to establish mathematical relationships between the non-asset and asset-related failure instances or modes, and factors that precipitate them.	Page 100

1.4.3.15 INVESTMENT PLANNING PROCESS REVIEW

Table 23 – Investment Planning Process Review Key Findings

#	Key Study Findings	Study Reference
1	Overall, Hydro One has implemented a consistent, thorough planning process that meets or exceeds expectations for a typical utility planning process in all areas.	Page 1

Table 24 – Investment Planning Process Review Recommendations

#	Recommendations	Study Reference
1	Improve condition data: Hydro One has made significant progress in ensuring its investment plans, and specifically its sustainment investments, are driven by an understanding of system and asset condition, but can continue to focus on developing potential investment projects using a rigorous, data-driven process. Hydro One aims to conduct condition testing on all end of life assets, and has processes in place to test critical stations and lines equipment. However, for some assets where a large share of the asset base is reaching end of life (e.g. conductors, insulators), Hydro One faces a backlog in condition testing. As a result, testing data is not available for all end of life assets, consistent with circumstances faced by many utilities with aging asset bases.	Page 3
2	Update asset strategies: Hydro One conducted a significant effort to update its asset strategies in parallel to its most recent planning cycle. Having updated asset strategies will strengthen Hydro One's asset management capabilities going forward. However, the parallel effort resulted in some asset strategies not yet being in place for the onset of 2017 planning process. Teams were able to leverage legacy asset strategies as they developed the 2017 plan, and the investments included in the plan align with the finalized asset strategies. As a result, the parallel nature of the asset strategy effort had limited impact on the quality of the plan.	Page 4
3	Increased outcome definition: In 2017, Hydro One was able to translate the results of its investment plan into expected customer outcomes with greater specificity than it had in previous years, leading to 5 year targets for key scorecard metrics. As Hydro One tracks actual performance against its forecasted outcomes, there is an opportunity to refine the accuracy of its forecasting methodology for future years, which will help Hydro One more accurately predict the outcomes provided by its investment portfolio. We would also recommend Hydro One leverage the same methodology to forecast 1 year outcomes for its scorecard metrics, in addition to the 5 year forecasts already in place.	Page 4

This report describes research sponsored by EPRI.

This publication is a corporate document that should be cited in the literature in the following manner:

Results of PTX Analysis of Hydro One's Transformer Fleet. EPRI, Palo Alto, CA: 2017. Supplemental Project Report.

ABSTRACT

This report describes the application of EPRI's Power Transformer Expert System (PTX) software to analyze Hydro One Networks Inc.'s fleet of transmission substation transformers to enhance Hydro One Networks Inc.'s ability to manage its transformer fleet.

A critical step in asset management is assessing the condition of in-service equipment accurately and efficiently. In no case is this more important than for substation power transformers. EPRI developed PTX to assess the condition of transformers by analyzing data from utility historical records, test results and name plate information. PTX identifies high-risk units for more detailed testing or increased monitoring which helps utilities to prioritize maintenance and replacements. The report provides an overview of PTX methodology and presents results of the Hydro One Networks Inc. analysis for each of the 729 transmission substation transformers for which data was provided.

INTRODUCTION AND BACKGROUND

Introduction

This report describes Hydro One's application of EPRI's Power Transformer Expert System (PTX) software to analyze its transformer fleet to assess short and long-term risk, determine failure rates and projections, and compare Hydro One's performance with the industry.

Background

Managing fleets of aging assets is a critical challenge for utility companies striving to maintain reliability and control costs in a constrained business environment. Transformer fleet management is an especially important subject for many utilities operating populations of power transformers that have significant numbers of units at or beyond their typically assumed design lives. Because a high percentage of transformers are approaching or even exceeding age forty, existing methods and a reliance on past performance may not be adequate for the effective management of this generation of transformers. Consequently, developing and justifying a repair/refurbish/replace management strategy for such populations and the rational basis for it, is a critical need.

EPRI's PTX integrates decades of expert knowledge and transformer performance data in a rule-based framework to provide a basis for asset management—including optimizing maintenance, increasing reliability, and capital planning decisions.

PTX assesses the present condition of transformers and identifies high risk units to support replacement strategies, monitoring needs and spares requirements. PTX also provides the user with a list of potential degradation or failure modes that may be occurring and the "belief" that PTX has that these conditions are actually in progress.

PTX evaluates the main tank, bushings and dielectric fluid modules and a generic framework for load tap changers.

The approach that the PTX software takes is intended to meet the following three objectives:

- Uses available information
- Incorporates advanced analytical capabilities
- Provides decision support for multiple stakeholders

Report Organization

In addition to this Introduction, the report is organized in the following chapters:

Chapter 2: Power Transformer Expert System (PTX): An Overview

Chapter 3: Results of PTX Analysis at Hydro One

Chapter 4: Hydro One Exploratory Graphics

2

POWER TRANSFORMER EXPERT SYSTEM SOFTWARE (PTX): AN OVERVIEW

This chapter presents a summary overview of PTX software. For this analysis PTX v4.0 was used to analyze Hydro One's fleet. The software is updated every year, with version 4.0 available in December 2017.

PTX Inputs and Outputs

PTX determines the present condition of a transformer using utility historical records and test results, along with each unit's name plate information.

Specific inputs to the software include:

Main Tank
- Dissolved gas in oil
- Furans and oil quality
- Family, make, application, age

Load Tap Changer
- Dissolved gas in oil
- Operations count
- Maintenance history
- Family, make, application, age

Bushings
- Power factor
- Capacitance
- Family, make, application, age

Dielectric Fluid
- Oil quality

PTX Outputs

As output, PTX produces a set of condition indices, as follows:

Main Tank Indices

- Normal Degradation Index
- Abnormal Degradation Indices
    - Core
    - Thermal
    - Electric

PTX also produces a Load Tap Changer Index, a Bushings Index, and a Dielectric Fluid Index. Note that the present analysis did not include assessment of the Load Tap Changers (LTC), as the condition assessment methodology for LTCs in PTX is not yet sufficiently mature for inclusion in this analysis. In addition, assessment of the transformer bushings was not performed.

PTX Condition Index Definitions

"Normal degradation" identifies units that may be approaching end of service life through expected degradation of paper from operation over an extended time.

"Abnormal degradation" identifies units that may be experiencing unexpected problems due to manufacturing defects or operating issues.

These transformers show the existence of some conditions that would not be present or expected in normal operation. This could be excessive temperatures that don't fit the pattern of gas seen with normally operating, heavily loaded transformers, or it could be some indication of partial discharge, arcing or sparking. Units with heating gases and no indication of paper involvement may also show up in the "abnormal core" category. The important difference, however, is that this index is NOT a function of service age. While some vintage-specific type issues may be involved, age does not increase or decrease an abnormal index. These conditions can occur at any point during the service life of a transformer. This index is more like other DGA condition categorizations but with significantly more intelligence and discrimination in the derivation of the indices' values. A high abnormal index value indicates a need to take more immediate action e.g. additional tests or monitoring or inspection. This index is useful for both maintenance and fleet and asset management.

Based on analyses of several transformer fleets, the following thresholds for each index have been established:

- 0.25 for the Normal Degradation Index
- 0.50 for the Abnormal Indices

These thresholds provide a reasonable signal to noise ratio based on experience to date. Transformers with indices above these thresholds should be evaluated by experienced personnel to establish future action.

Time to Action

Normal degradation is a slow process. Units with elevated Normal Degradation Indices are not expected to experience a rapid deterioration in condition in the near term.

Abnormal conditions, as represented by the Abnormal Condition Indices, may or may not evolve to a failure rapidly. The time to failure, should a failure occur, is highly variable. Certain conditions may be more severe, and thus more likely to evolve to failure more rapidly. In general, high Abnormal Condition Indices should be investigated immediately.

Development History and Data Points

The development of PTX had its origins in EPRI's XVisor project in the 1990s. XVisor was an early transformer expert system developed with extensive engagement and input from industry subject matter experts. The PTX development effort began in 2007 with a concept that involved multiple stakeholders and the analysis of readily available data from large transformer fleets. PTX Version 4, released in 2017, has been tested with data from some 32,000 transformers from 22 utility fleets—a total of 400,000-plus test data points. This work is documented in the EPRI technical update report *Analytics Assessment and Comparisons.* EPRI, Palo Alto, CA: 2017. 3002010221.

Normal Degradation Index (NDI) versus Degree of Polymerization (DP) is a much smaller data set. Paper samples are taken from transformers that have been analyzed with PTX, but few opportunities are available to obtain those samples. On occasions when a utility tears down a transformer, samples are taken and sent for laboratory analysis to determine DP to plot against NDI. Figure 2-1 presents a comparison of test results from retired transformers for DP versus NDI.

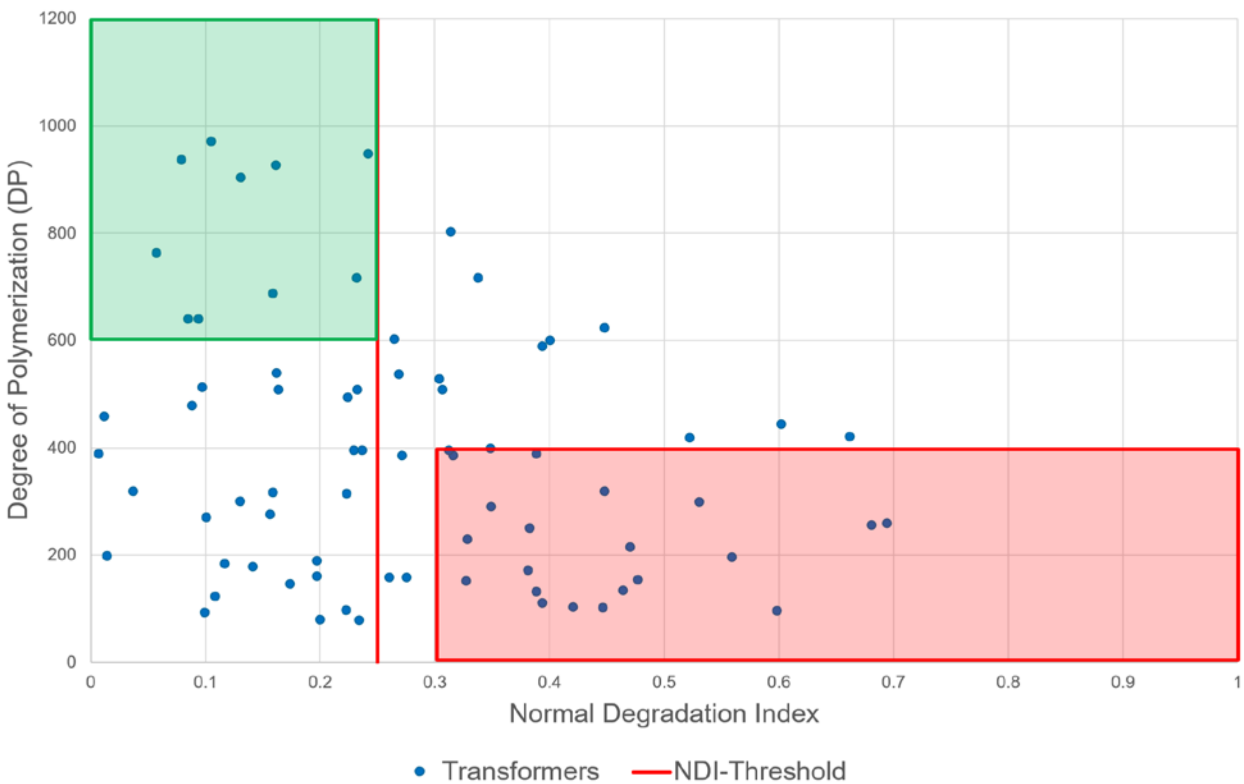

Figure 2-1
Comparison of Test Results from Retired Transformers (DP) and PTX Analysis

The test results show good correlation between NDI and actual paper condition, and the established threshold for concern (0.25) seems appropriate based on the samples obtained thus far. Although more samples are needed to improve confidence, the Normal Degradation Index is a useful indicator of paper condition.

Abnormal Index Validation

Case studies are useful, but do not provide a quantitative means for measuring effectiveness. With historical data on transformers that have failed, transformers removed from service before impending failure, and from healthy transformers, researchers can retroactively assess the performance of both PTX and other methods in blind back-testing.

For example, Figure 2-2 shows a performance evaluation approach for assessing the efficacy of different approaches at detecting faulty transformers using dissolved gas in oil analysis (DGOA). Table 2-1 shows the results of diagnostic methods evaluations.

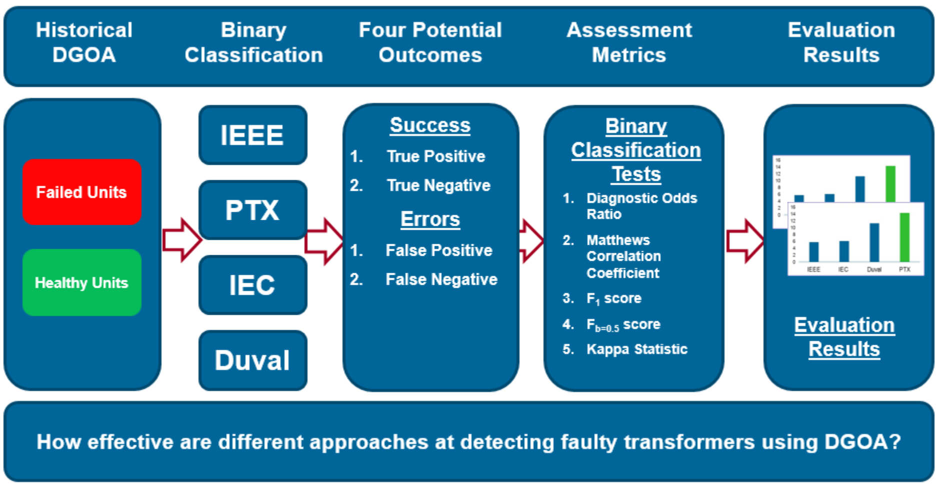

Figure 2-2
Performance Evaluation Approach

Table 2-1
Diagnostic Methods Evaluation

Performance Measure	PTX Rank Versus Other DGA Diagnostic Methodologies
Diagnostics Odds Ratio (with 95% Confidence Interval)	1st
Matthews Correlation Coefficient	1st
F_1 Score	1st
$F_{b=0.5}$ Score	1st
Kappa Statistic	1st

3
RESULTS OF PTX ANALYSIS AT HYDRO ONE

Introduction

EPRI worked with Hydro One to apply PTX version 4 to analyze the company's transformer fleet to:

- Identify transformers at risk
- Determine failure rates and projections
- View and compare performance with the industry

The analysis included 728 transformers and was limited to main tank DGA and Oil Quality samples from 1984 to 2017. The DGA and oil quality sample counts by year are shown in Figure 3-1.

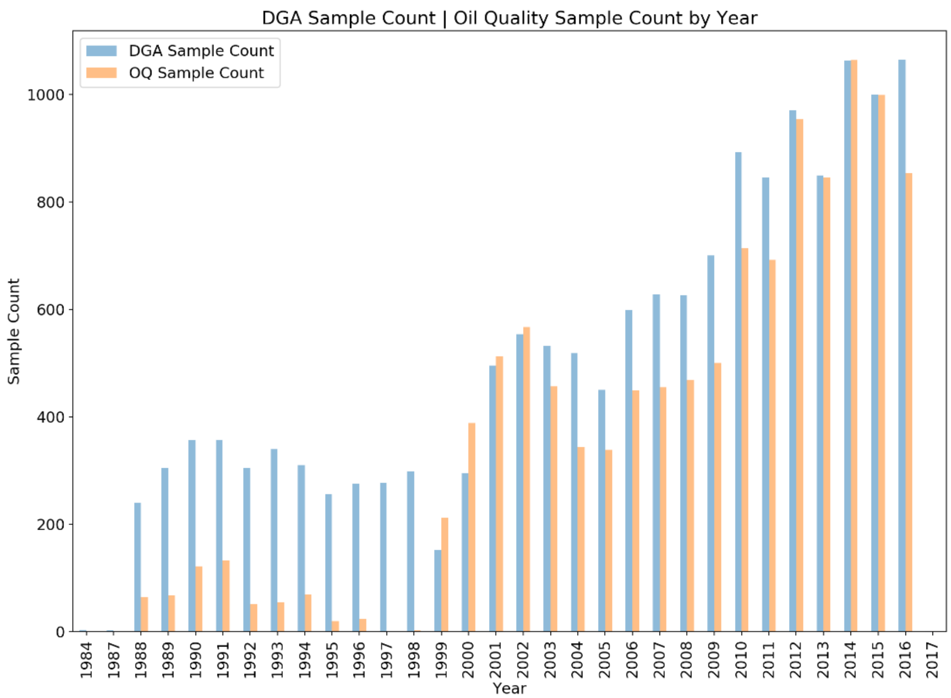

Figure 3-1
DGA and Oil Quality sample counts by year

- 129 transformers were flagged by PTX for elevated Normal Degradation Index (NDI)
- 88 transformers were flagged for elevated Abnormal Indices, as follows:
    - 10 Abnormal Thermal
    - 87 Abnormal Electrical

- 35 Abnormal Core

Transformers can have multiple elevated indices from one PTX analysis.

The tabulated results are presented in a spreadsheet in Appendix A.

Figure 3-2 shows the number of transformers by vintage.

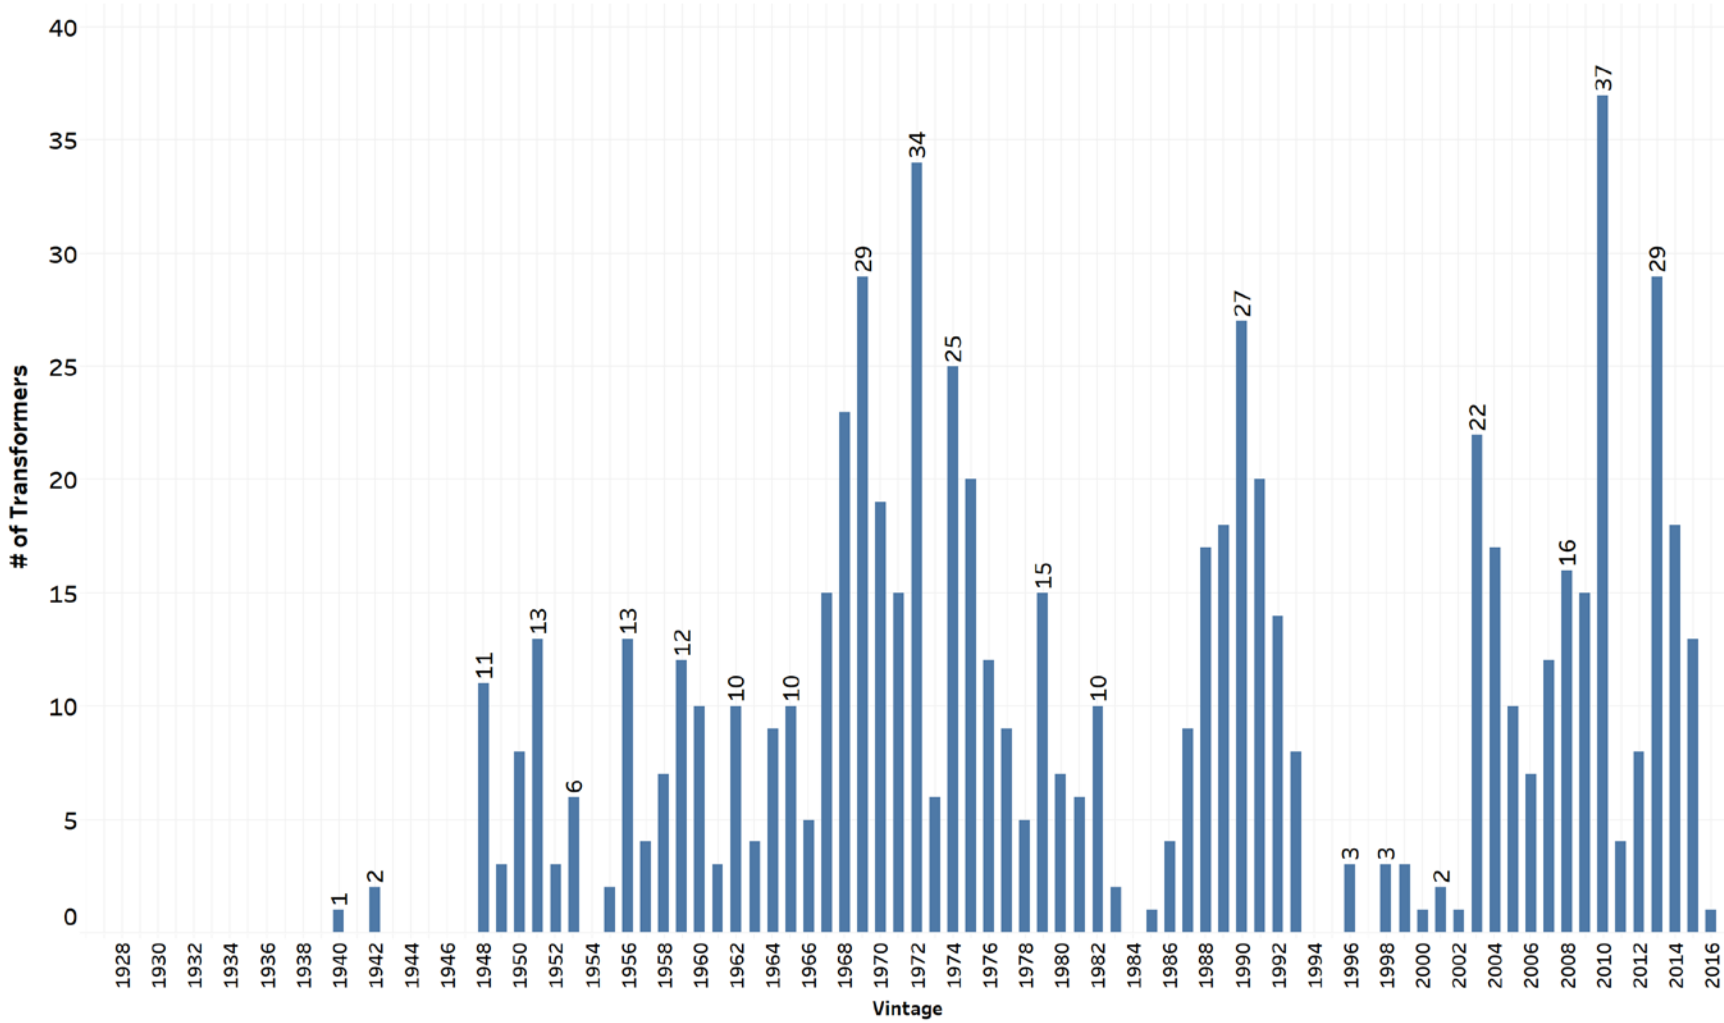

Figure 3-2
Number of Transformers by Vintage

Figure 3-3 shows transformers with elevated NDI by vintage.

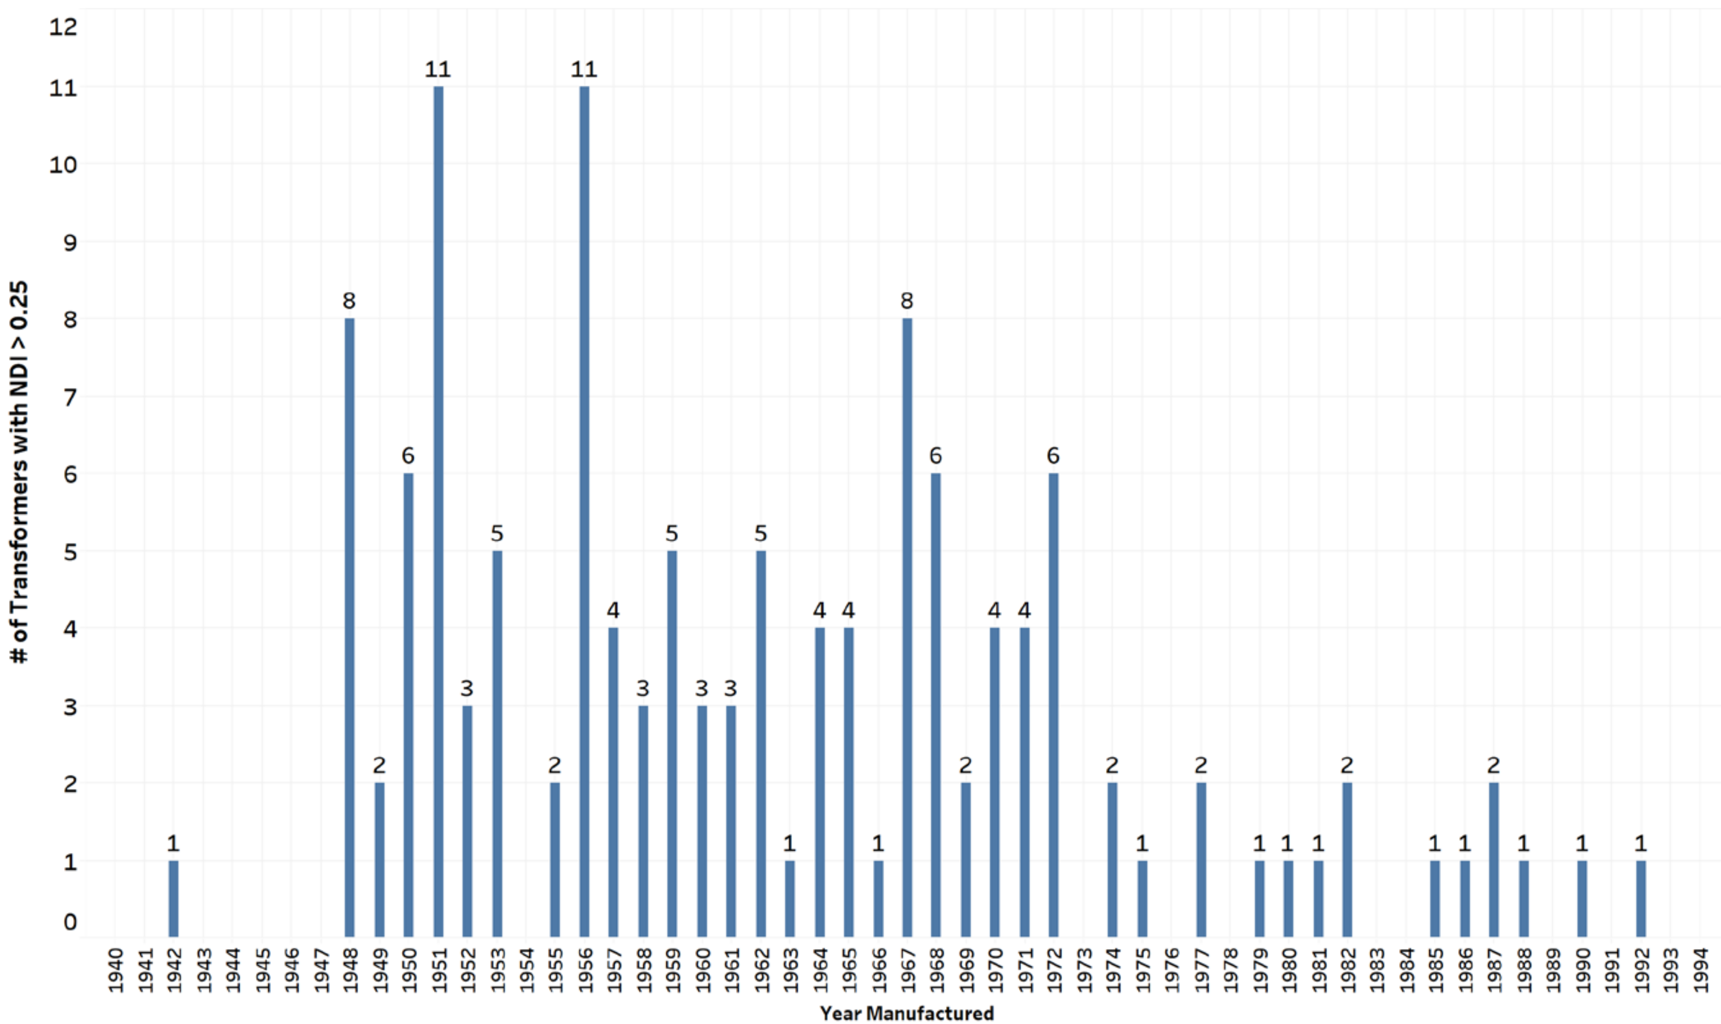

Figure 3-3
Transformers with Elevated NDI by Vintage

Figure 3-4 shows transformers with elevated abnormal indices by vintage. "Elevated abnormal indices" is defined by Abnormal Condition Code values greater than 3. Abnormal Condition Code is a metric that takes the maximum value of all abnormal indices for an individual transformer.

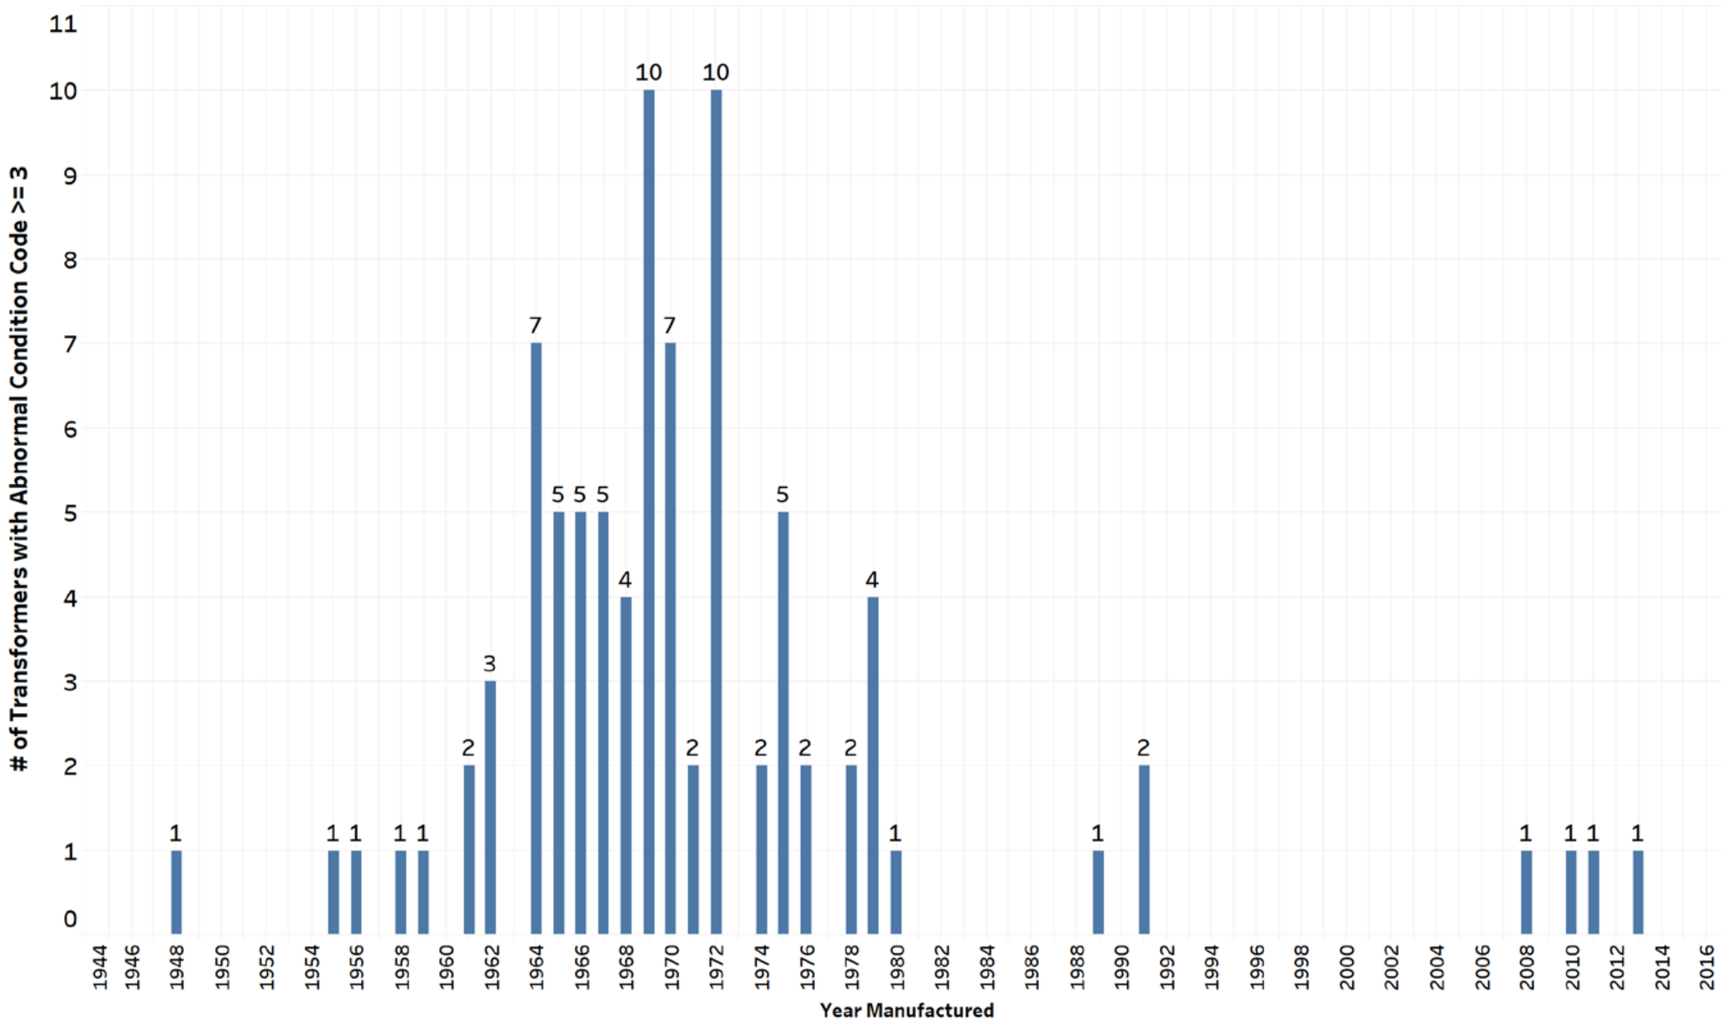

Figure 3-4
Transformers with Elevated Abnormal Indices by Vintage

Figure 3-5 is a histogram of NDI by voltage class. On the x-axis, NDI values are grouped with a bin size of 0.05. On the y-axis, the number of transformers is plotted for each voltage group per NDI bin. For example, SN:1191766, a 228.8 kV autotransformer manufactured in 1956, is in the 230 kV voltage group. Its NDI value of 0.63 puts it in the 0.60 bin which ranges from 0.60 to 0.65.

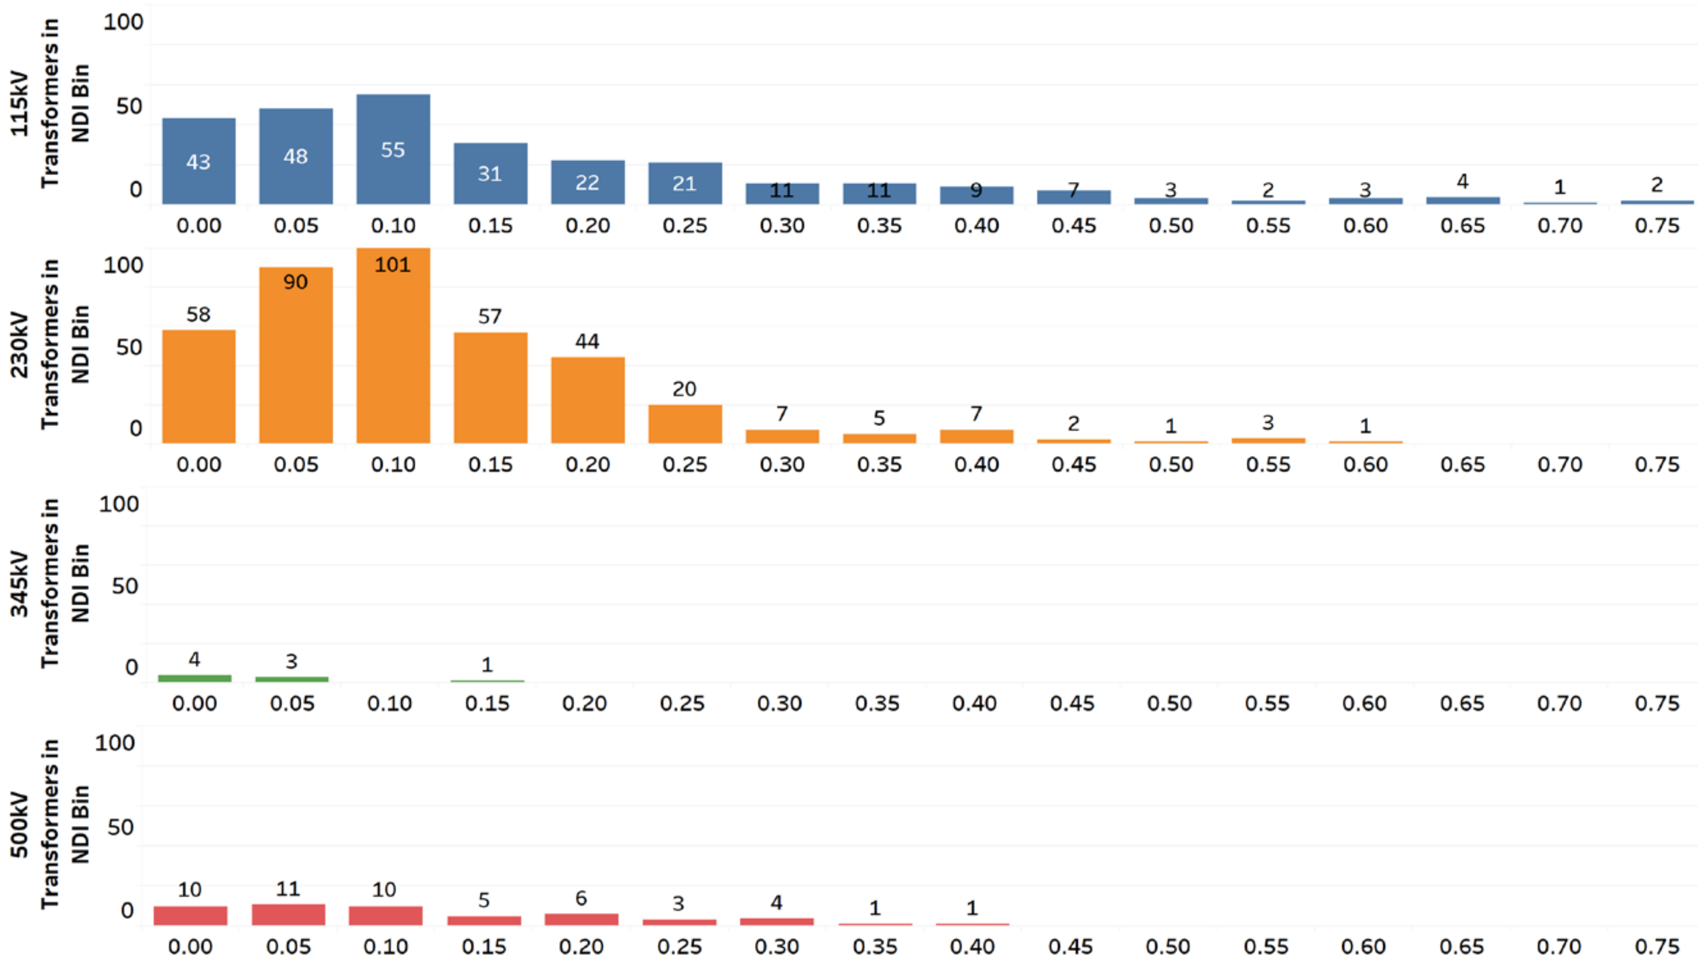

Figure 3-5
Histogram of NDI by Voltage Class

Figure 3-6 shows the number of transformers flagged by voltage class. For the Normal Degradation Index, a “flagged” means that a transformer’s NDI value is greater than 0.25. Flagged Abnormal Thermal transformers have an Abnormal Thermal value greater than or equal to 0.6. Flagged Abnormal Electrical transformers have an Abnormal Electrical value greater than or equal to 0.5. Flagged Abnormal Core transformers have an Abnormal Core value greater than or equal to 0.5.

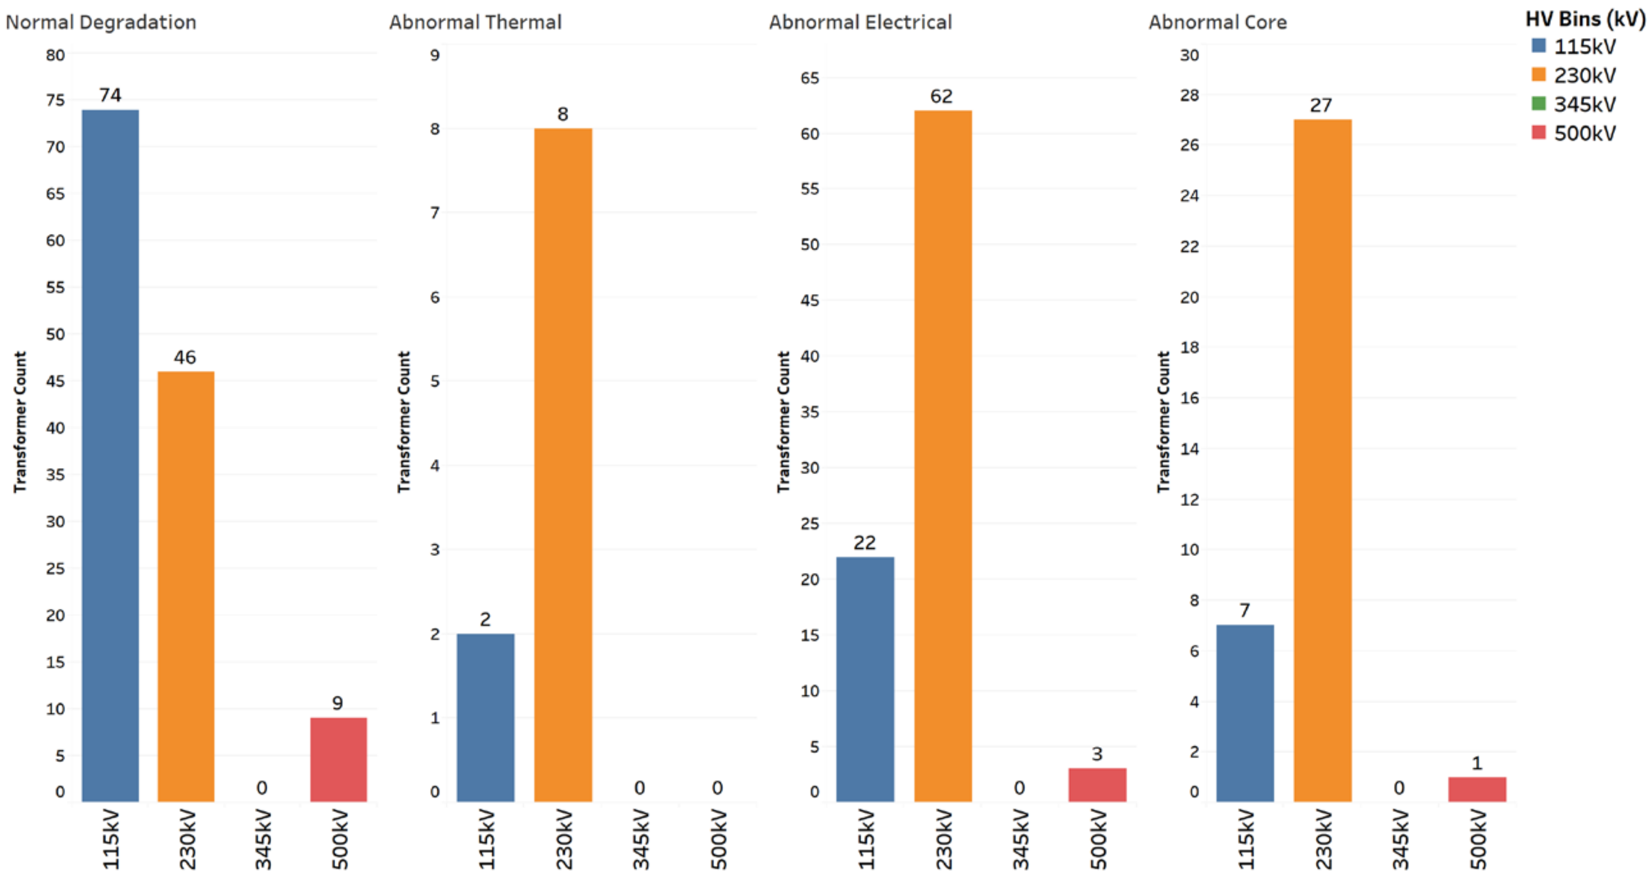

Figure 3-6
Number of Transformers Flagged by Voltage Class

Figure 3-7 shows transformers flagged abnormal by manufacturer. The top histogram shows total counts of transformers by manufacturer. The bottom histogram shows the number of transformers that have been flagged for any Abnormal Condition (Abnormal Thermal, Abnormal Electrical, and/or Abnormal Core).

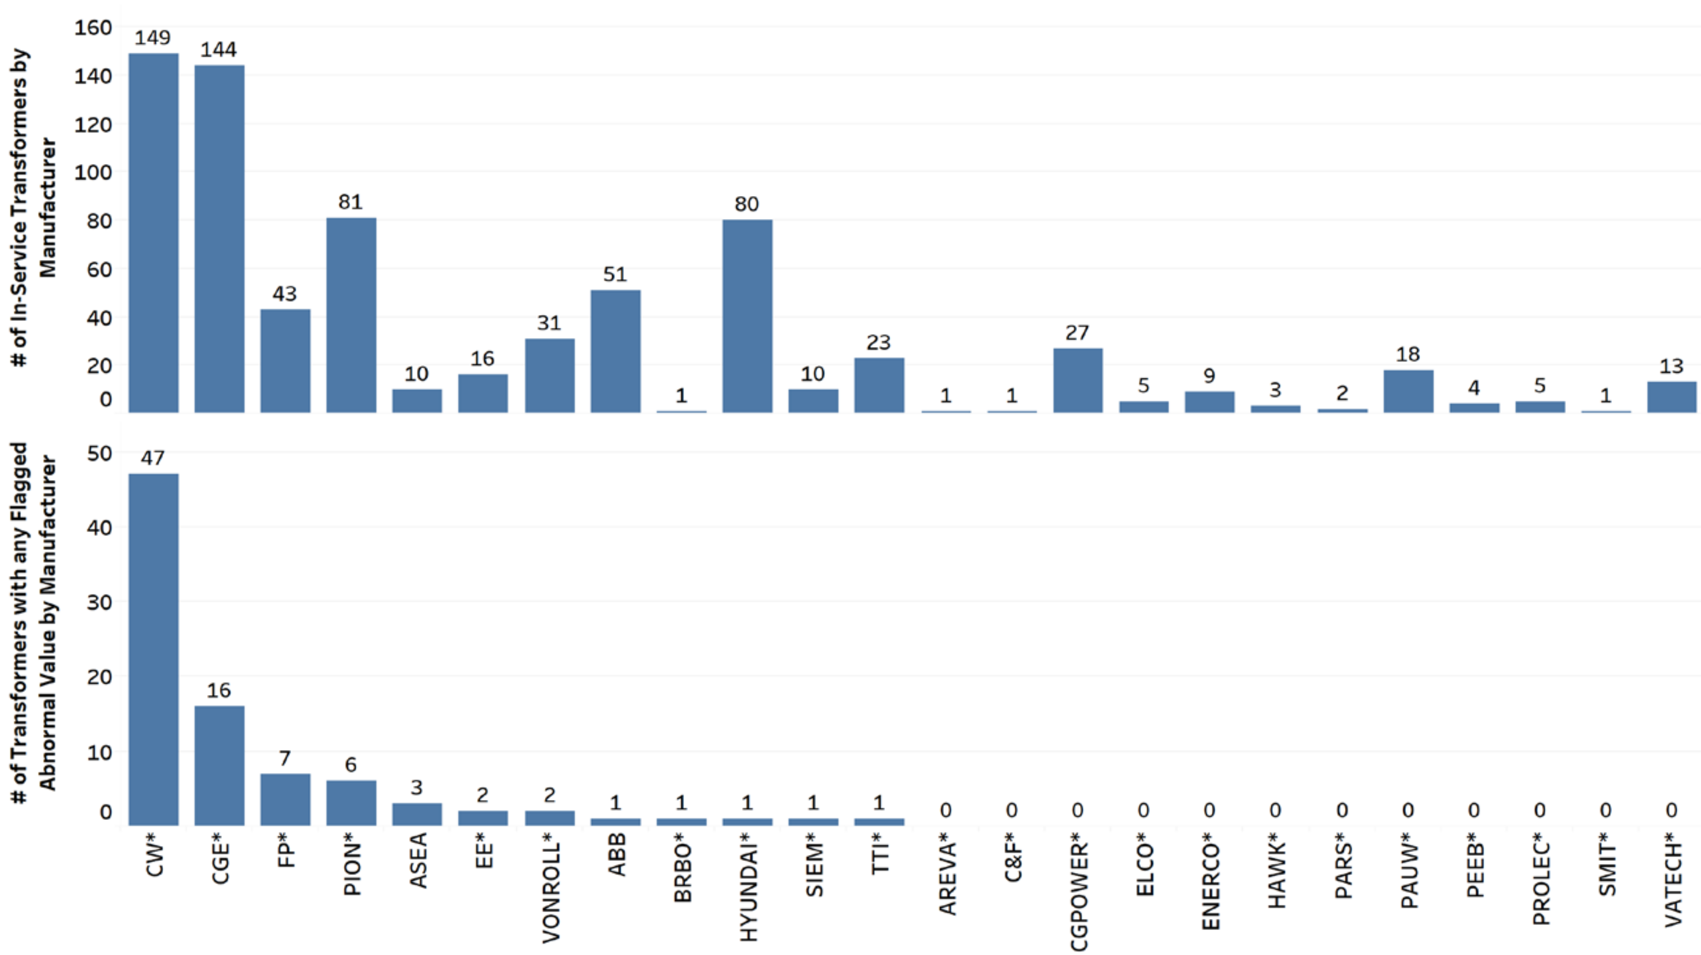

Figure 3-7
Transformer Flagged Abnormal by Manufacturer

Figure 3-8 presents histograms of abnormal indices for Canadian Westinghouse. The top histogram shows the total count of Canadian Westinghouse transformers by Abnormal Thermal 0.1 bins. The bottom histogram shows the total count of Canadian Westinghouse transformers by Abnormal Electrical 0.1 bins.

Figure 3-8
Histograms of Abnormal Indices for Canadian Westinghouse

500 kV Autotransformers above Threshold for Abnormal Indices

Table 3-1 shows transformers in the 500 kV voltage group with any flagged abnormal index value, as described before Figure 3-6. Figure 3-9, Figure 3-10, and Figure 3-11 show the DGA and PTX results for these units. Note that Hanmer T9 (B) and Porcupine T7 have been replaced.

4
HYDRO ONE EXPLORATORY GRAPHICS

Introduction

This chapter provides graphical representation of the analysis results presented in Chapter 3 developed at Hydro One's request using their five-category ranking:

1. Very Good
2. Good
3. Fair
4. Risk
5. High Risk

Results of this effort are tabulated in a spreadsheet presented in Appendix A.

Table 4-1 shows the five-category ranking and corresponding metrics driven by the Normal Degradation Index (NDI). Table 4-2 shows the five-category ranking and corresponding metric driven by the Abnormal Indices (AI) as discussed in Chapter 2. The thresholds for the five-category ranking are based on subject matter expertise, informed by experience to date with application of PTX.

Note that this ranking, and the graphical representations presented in this chapter, show one possible way of grouping transformers. Other combinations are possible, including grouping by voltages, station names, geographical regions, and criticality.

Table 4-1
Category Thresholds for Normal Degradation Index

Ranking Category	Normal Degradation Index Thresholds
Very Good	0.0 to 0.1
Good	0.1 to 0.25
Fair	0.25 to 0.4
Risk	0.4 to 0.5
High Risk	>0.5

Table 4-2
Category Thresholds for Abnormal Indices

Index	Category 1 – Very Good	Category 2 - Good	Category 3 - Fair	Category 4 - Risk	Category 5 – High Risk
Electrical	0.0 to 0.3	0.3 to 0.5	0.5 to 0.6	0.6 to 0.7	> 0.7
Thermal	0.0 to 0.3	0.3 to 0.6	0.6 to 0.8	0.8 to 0.9	> 0.9
Core	0.0 to 0.3	0.3 to 0.5	0.5 to 0.7	0.7 to 0.9	> 0.9

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

Derivation of Transmission Substation Transformer Hazard Functions: EPRI, Palo Alto, CA: 2018.

ABSTRACT

A key goal of asset management is to base decisions on an equipment fleet's mean life expectancy. Insights on the fleet mean life expectancy may be derived from careful analysis of historical replacement data. This report describes EPRI work to model and develop transformer removal hazard rates from historical replacement records and apply them to forecast the number of transformers expected to require replacement based on past replacement practices.

EPRI has developed a methodology using advanced statistical techniques for analyzing transformer historical replacements and applied it to the Hydro One Networks Inc. transmission substation transformer fleet. Hydro One Networks Inc. provided in-service, failure and removed from service data for their transformer fleet. Using this data, EPRI developed models for removal rates of transformers as a function of their age. The models along with information about the current fleet were used to project the number transformers expected to be removed from service over the next five year period assuming past practices are continued to be followed. The results are provided in transformer fleet groups (high side voltage in kV) as follows: 115, 230, and 500.

LIST OF TABLES

1

SUPPLIED TRANSFORMER DATA

Data Received

Hydro One Networks Inc. (Hydro One) provided the following data as shown in Table 1-1. The transformer fleet has been grouped by high side voltage in kV and whether the unit is an auto or non-auto.

Table 1-1
Transformer Group Data

Group	In-service	Failures	Removed from Service
115 kV Non-Auto	276	19	297
230 kV Non-Auto	303	15	76
230 kV Auto	94	3	25
500 kV Auto	48	8	21
500 kV 250 MVA Auto Single Phase	12		8
500 kV 750 MVA Auto Three Phase	32		10

In-service Data

The in-service data provided by Hydro One consists of 721 transformers as of first quarter 2017. The data included the following fields:

- Substation
- Transformer Position
- Serial Number
- Manufacturer
- Auto Transformer (Yes/No)
- HV Winding Volts
- LV Winding Volts – 01
- LV Winding Volts – 02
- Tertiary Winding Volts

- Top MVA Rating
- Number of Phases
- Date Installed
- Age

Figure 1-1 shows the age demographics of the in-service transformer fleet as of first quarter 2017.

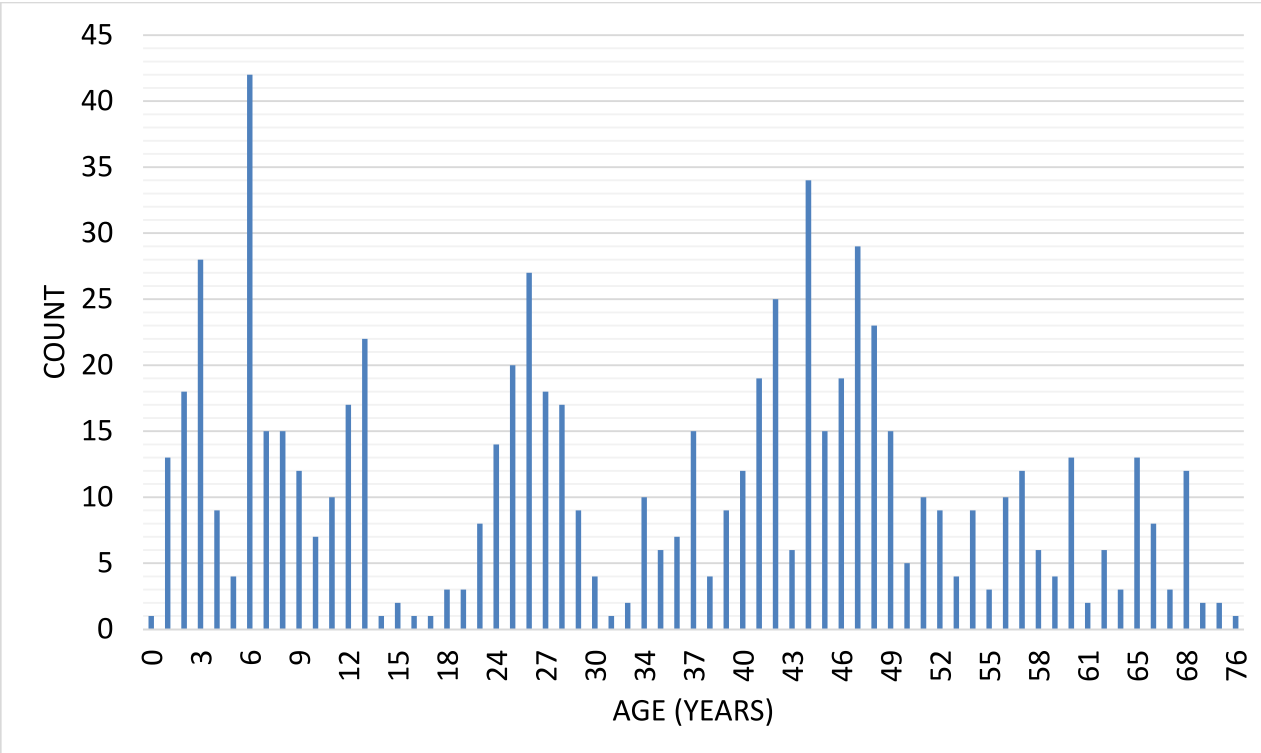

Figure 1-1
In-service Transformer Age Demographics

Removed from Service Data

The removed from service data provided by Hydro One consists of 419 transformers as of first quarter 2017. The data included the following fields:

- Substation
- Transformer Position
- Serial Number
- Manufacturer
- Auto Transformer (Yes/No)
- HV Winding Volts

- LV Winding Volts – 01
- LV Winding Volts – 02
- Tertiary Winding Volts
- Top MVA Rating
- Number of Phases
- Date Installed
- Date Removed
- Age

Figure 1-2 shows the age demographics of the removed from service transformers from the period of 1981 to first quarter 2017.

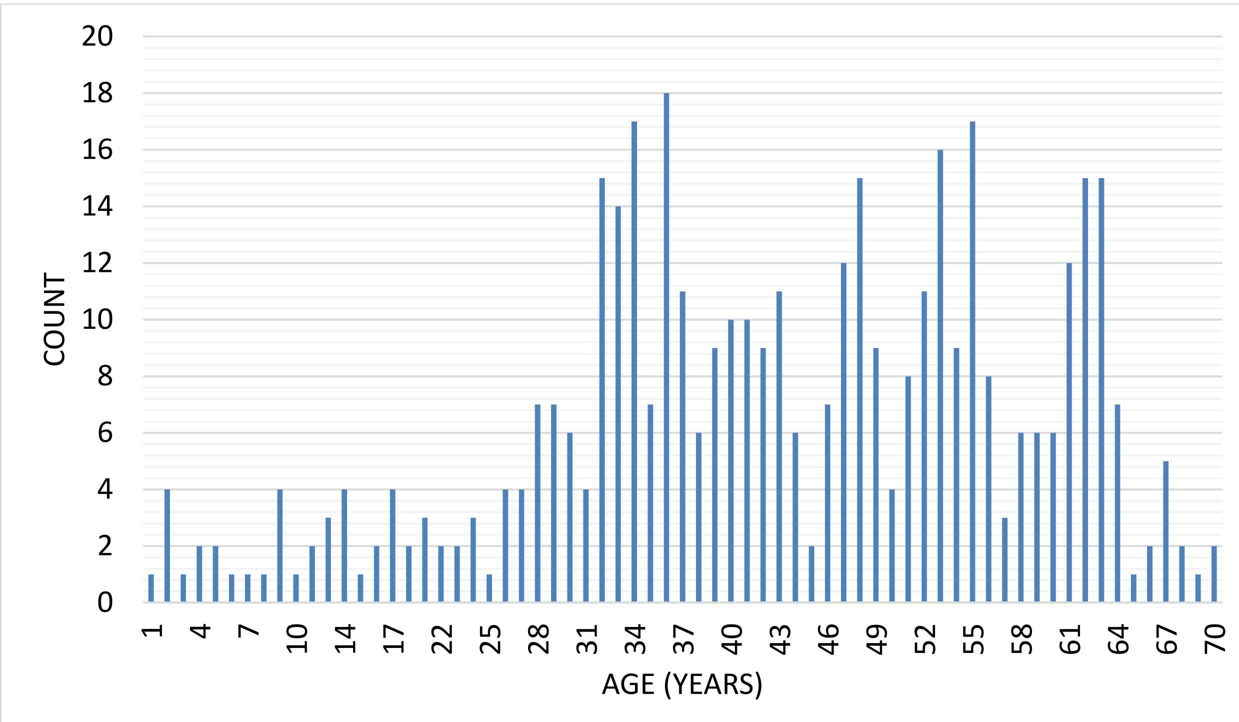

Figure 1-2
Removed from Service Transformer Age Demographics

Failure Data

The failure data provided by Hydro One consists of 42 transformers as of first quarter 2017. The data included the following fields:

- Substation
- Transformer Position

- Serial Number
- Manufacturer
- Auto Transformer (Yes/No)
- HV Winding Volts
- LV Winding Volts – 01
- LV Winding Volts – 02
- Tertiary Winding Volts
- Top MVA Rating
- Number of Phases
- Date Installed
- Date Failed
- Age
- Failed Component

Figure 1-3 shows the age demographics of the failed transformers from the period of 2006 to fourth quarter 2016.

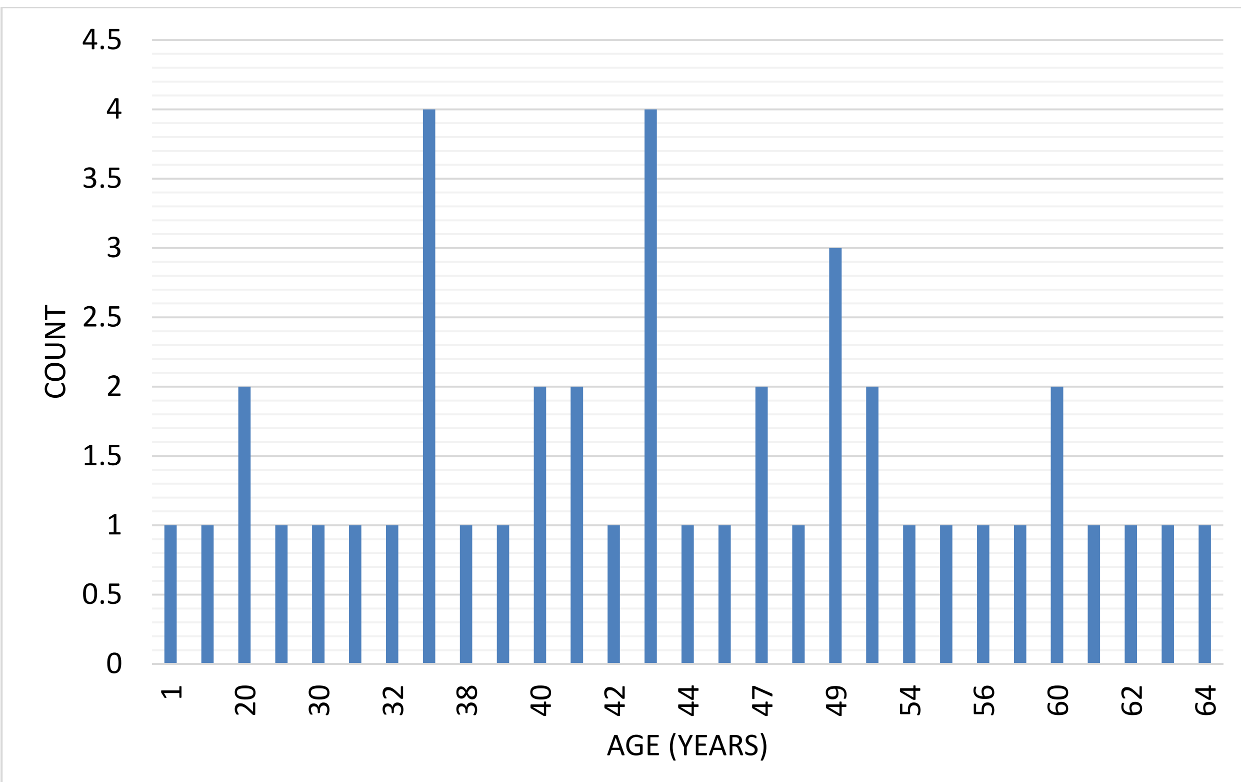

Figure 1-3
Failed Transformer Age Demographics

2
REMOVAL RATE MODELING

Data Review

Originally Hydro One sought to obtain a year-by-year prediction of the expected number of transmission substation transformer failures for the next five years. However, the supplied failure data appeared sparse in relation to the number of transformer-years experienced and consequently the derivation would not provide a usable failure hazard rate. The failure data provided for the period of 2006 through 2016 consists of 42 failures. Confidence limits for any derived hazard rate would be large using this supplied failure data as noted in Figure 2-1. For example, for the failure rate of derived from this data could be anywhere between approximately 0.6% and 2% for a 60 year old transformer using a 95% confidence band. For a 40 year old transformer the failure rate could be anywhere between approximately 0.3% and 1%.

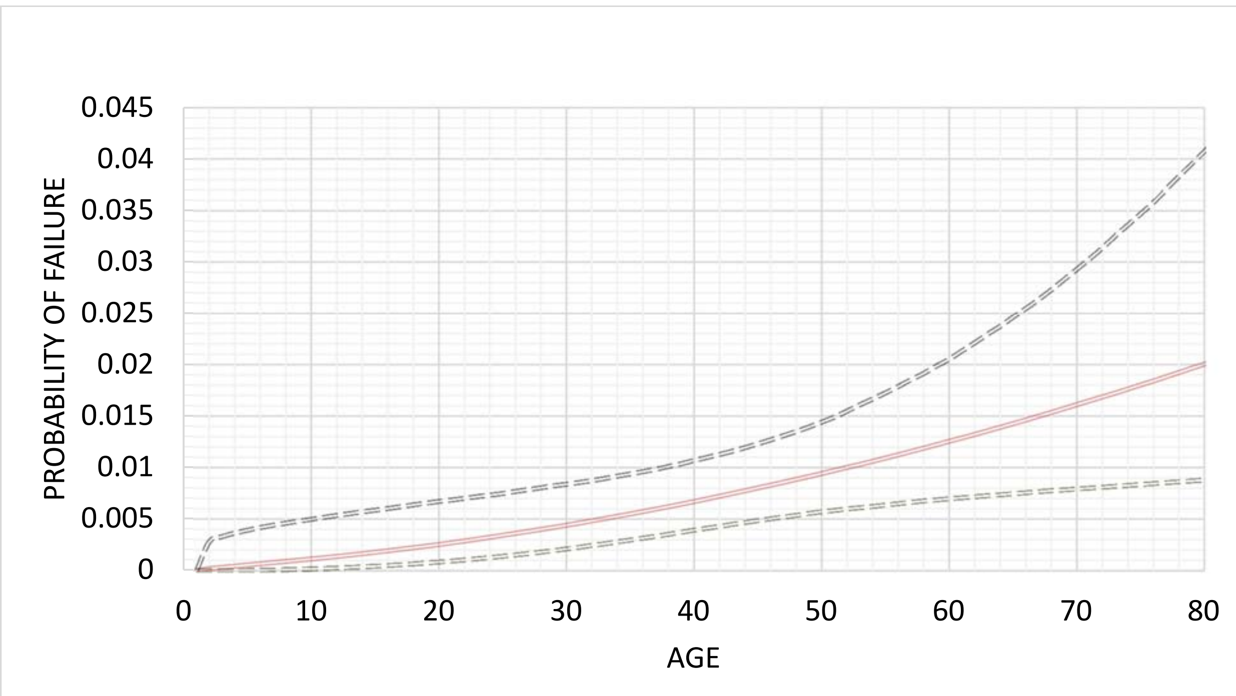

Figure 2-1
Failure Hazard Rate Derived from Spares Data

However, removed from service data is more abundant and consist of 419 transformers within a period of 1981 to first quarter 2017. The reasons for removal are not supplied in data, therefore failures and discretionary replacements cannot be distinguished. Since the reason is not supplied a time-to-event model can be developed where the event, rather than failure, is removal.

Figure 2-2 show the Service Ages of the 115 kV transformer group using data from both the removed from service (left) and failures (right). In the Service Ages plot, the horizontal axis is the age of the transformers. Each horizontal line represents a distinct transformer denoted by an index number. The failures (or removals) and non-failures are separated and then ordered by installation date. The horizontal line lengths represent the ages for which each transformer was in the record, that is, how long it was observed after the truncation date. The left end point of each horizontal line is the Enter Age. The vertical red lines are failure ages. This figure shows clearly that there were no transformers that failed before age 20 in this data set. The removed from service data provides a longer observation period and many more events than the failure data.

Figure 2-2
Service Ages for 115kV Transformer Group

Modeling

EPRI has developed a proven analytic methodology for analyzing transformer event data. The methodology has been demonstrated with a number of utilities' datasets. The modeling methodology assumes a Weibull function for the underlying data described by two parameters, shape and scale. The problem is then to develop the most likely shape and scale values. A Bayesian approach is utilized.

Analysis began with a "prior distribution" based on the results of EPRI observations of previous utilities transformer data set of in-service and failures. In the Bayesian paradigm, this current knowledge about the model parameters is expressed by placing a probability distribution on the parameters, the prior distribution. As new data, that is removal observations, becomes available, the information contained regarding the model parameters is expressed in a likelihood, which is proportional to the distribution of the observed data given the model parameters. This information (from removal data) is then combined with the prior distribution to produce a new, upgraded probability distribution formally called the posterior distribution or updated distribution. The calculation involves multidimensional integration of complicated functions and is computationally intense and a Markov Chain Monte Carlo, MCMC, method was used.

Figure 2-3 is a bivariate plot showing the calculation results for removal for this transformer population. The blue dots represent a random sample of 9,600 pairs from the updated distribution of shape and scale given the information from the data provide Hydro One. The red ellipse contains the central 95% of the distribution, that is, where most (95%) of the pairs are located. The red dot is the mean of the upgraded Weibull parameter knowledge, the expected values. From these upgraded shape and scale parameters removal predictions for currently in-service transformers can be made.

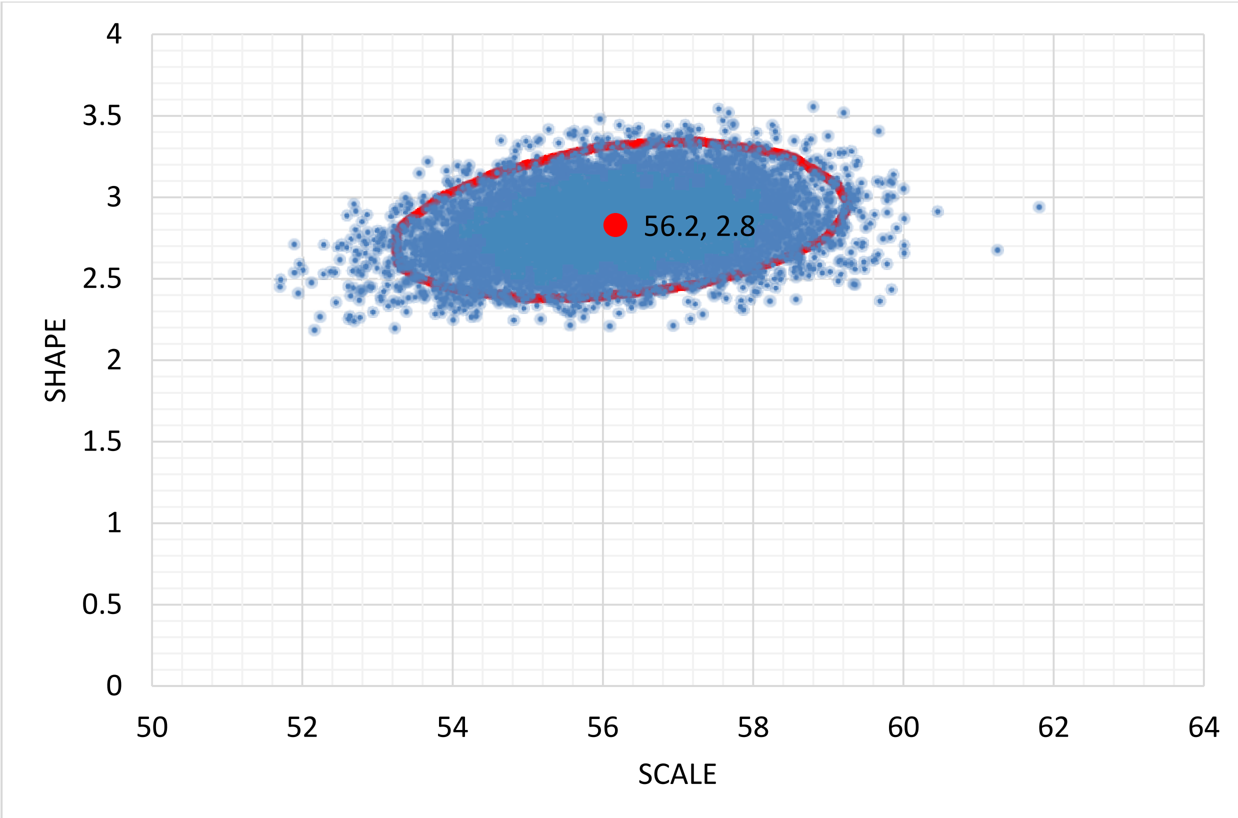

Figure 2-3
Bayesian Result 115 kV Transformers

Fitting the data to the Model

The removal rate model is verified by comparing the sample cumulative hazard function calculated from the actual event data (previously described) against the cumulative hazard functions created from the Weibull model. There are cumulative hazard functions for each MCMC observation. For each age from 0 to 100, we calculate the median cumulative hazard rate and the corresponding 95% credibility interval. This calculation provides the median cumulative hazard rate (solid red line) for the model shown in Figure 2-4. The dashed red lines give the 95% credibility interval for these calculations. The black line is the actual event data cumulative hazard function calculated using the Nelson-Aalen technique. The Nelson-Aalen technique is an established statistical technique for developing a non-parametric estimate of the cumulative hazard function based on the observed data.

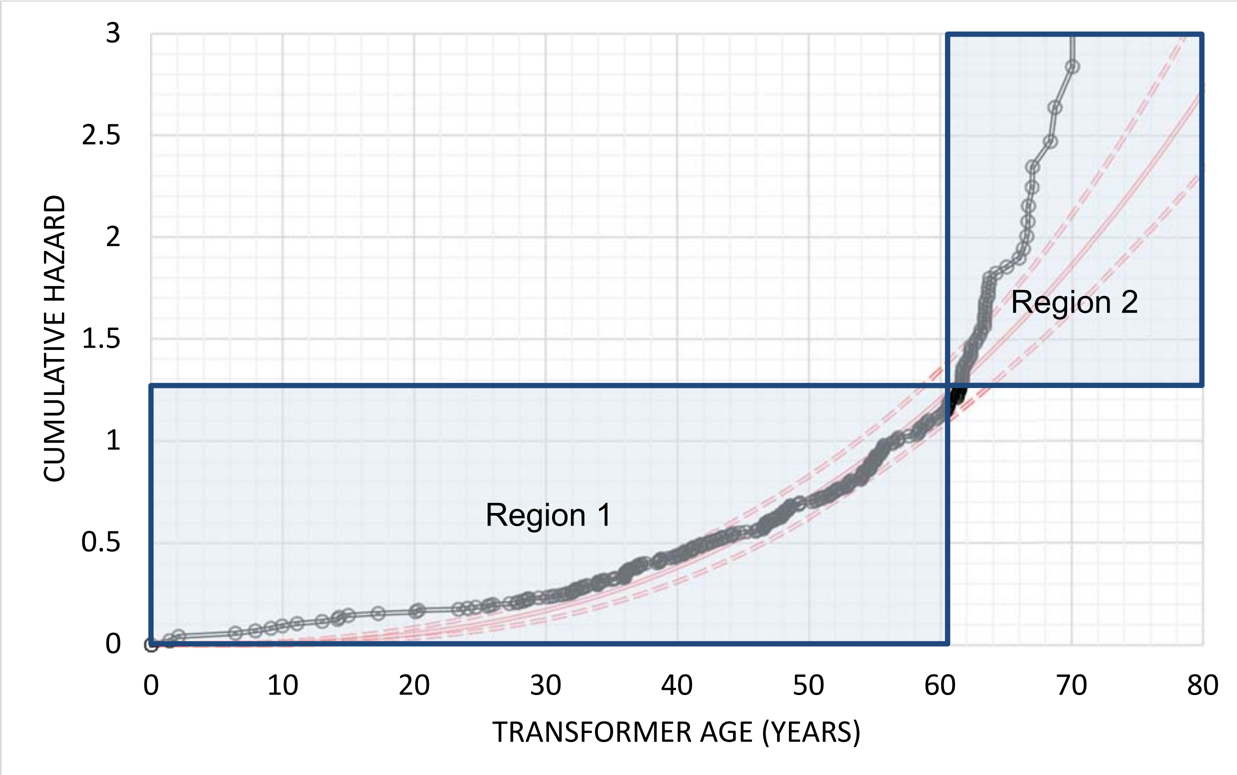

Figure 2-4
Comparison of Model and Sample Cumulative Hazard Functions 115 kV Transformers

Figure 2-4 for the 115 kV transformer group show two regions with different levels of agreement between the red and black lines. A good Weibull model fit for most of the life (Region 1) and a much steeper replacement rate (black line) than provided by the Weibull model in later life (Region 2). However, younger power transformers are rarely replaced except for failure. Therefore, Region 1 may be a reasonable model for the failure hazard rate. The break points between the two regions could indicate the following:

- The onset of a failure process that is more dominant in older units.
- The result of discretionary replacement decisions.
- Some combination of both failure process and discretionary replacement.

Since the reasons for removal are not noted, failures and discretionary replacements cannot be distinguished.

Modeling Assumptions

- The starting data is complete and contains all removals and in-service units for the period within 1981 through first quarter 2017.
- The criteria for removal have been constant over the historical period being analyzed.
- Future criteria for removals will be the same as in the past.

- Any external effects on removal rates (e.g. budget constraints) were constant over the historical period and will be unchanged over the forecast period.
- Underlying wear-out processes will not change.

Modeling Results

There are currently 276 115 kV family transformers in service of various ages. Based on the age of each individual transformer, the distributions of the number of removals was predicted from a Monte Carlo simulation.

Each of the 9,600 pair results from the analyses results (Figure 2-3) is used in a Monte Carlo simulation to generate the expected number of removals. Each shape and scale pair defines a Weibull distribution. This distribution is applied to each of the in-service transformers and the number of removals are summed for the total population for that particular distribution.

The resulting histogram of the sum of the number of removals recorded in each plot (Figure 2-5) gives the probability distribution of removals. The entire process is then repeated for the next year with each transformer's age incremented by one.

Figure 2-5 shows the predicted number of removals of the currently in-service transformers for each of the next five years and the five year total.

The figure can be interpreted as probability distributions. For example, in the plot for year 1, adding up the probabilities corresponding to 0 through 18 removals, we can say that we are 99% certain that the number of transformer removals will be 18 or fewer.

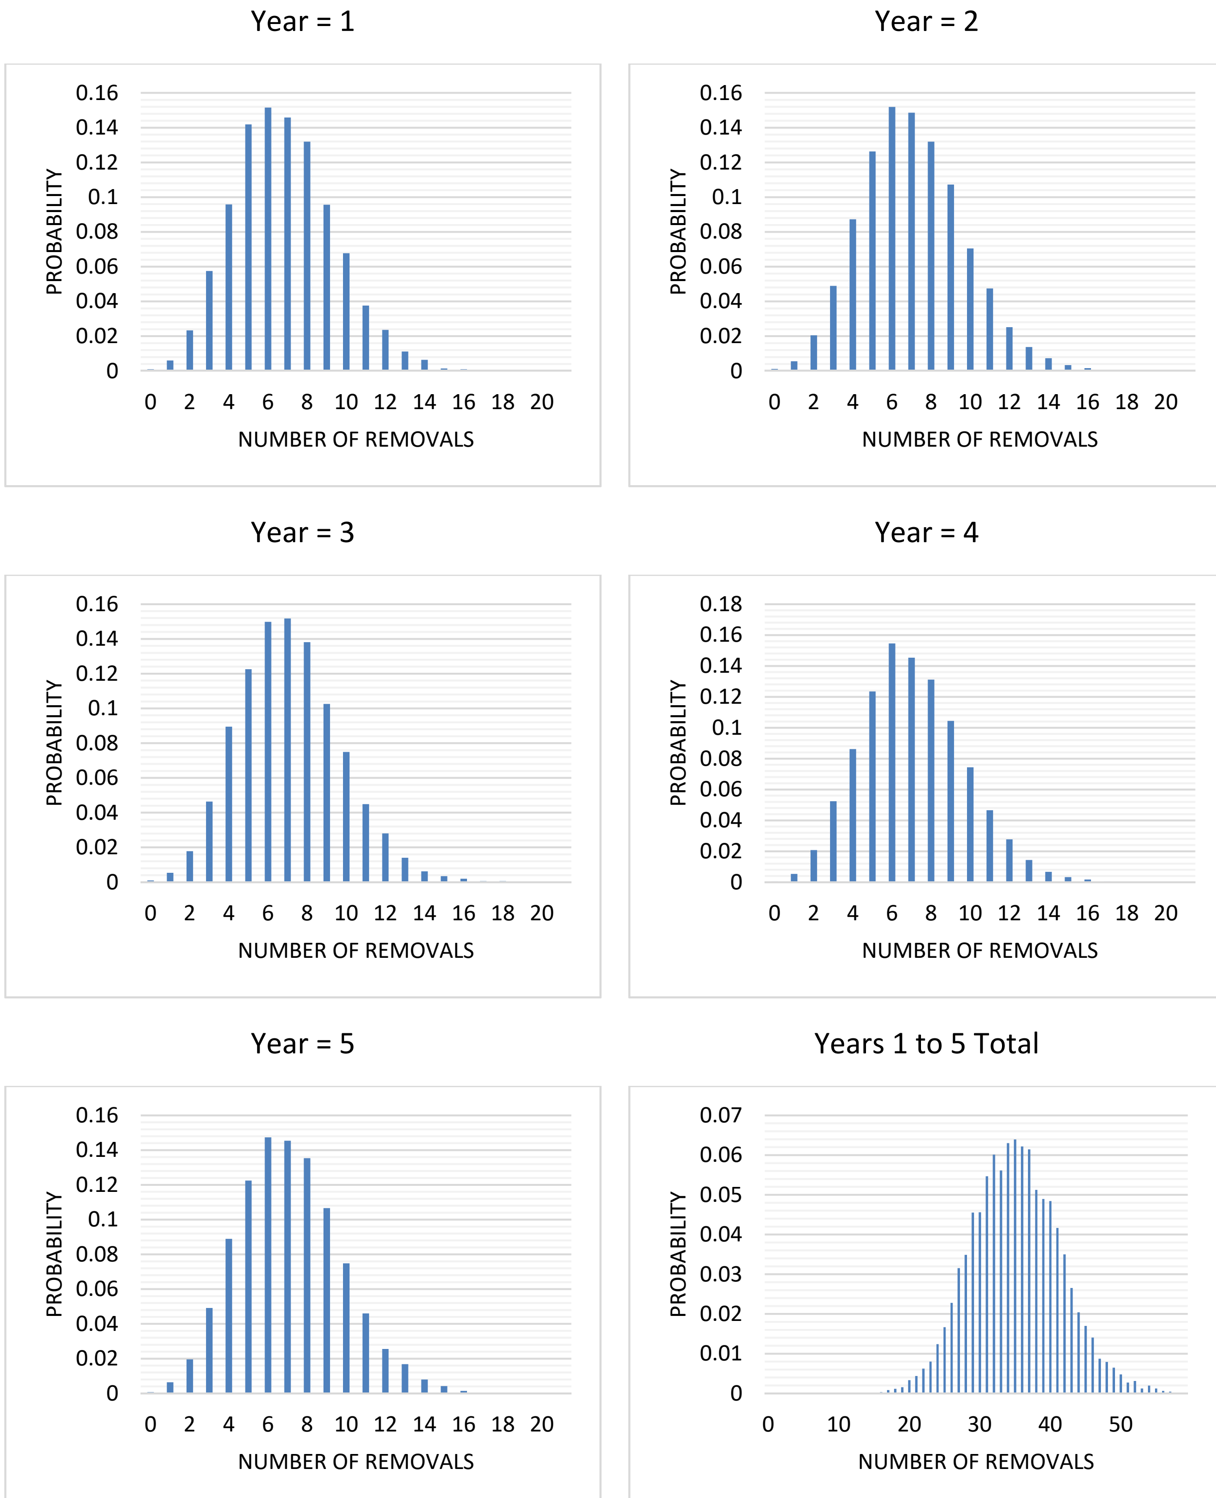

Figure 2-5
Predicted In-Service Transformer Removals for Each of the Next Five Years 115 kV Transformers

3
REMOVAL ANALYSIS RESULTS

Using the data provided by Hydro One describe in Chapter 1. The following chapter provides the results of the application of the model describe in Chapter 2 for each of the transformer groupings. The analyses were grouped by transformer high side voltages, 115 kV, 230 kV and 500 kV. More granular groupings, for example by number of phases or MVA, were not feasible because of the lack of data or the reduced number of data points that would result.

Each group results will include the following:

In-service Age Demographics: Shows the age distribution in years for the specific transformer group.

Removed from Service: Shows the age distribution in years for the specific transformer group.

Service Eras: Provides information about the completeness of the data set. The horizontal axis is in years. Each horizontal line represents a transformer recorded. The black lines show the installation dates. If a line is gray, the transformer is still in service. If a line turns red, the transformer has been removed from service on the date of the color change.

Service Ages: Provides information about the completeness of the data set. The horizontal axis is the age of the transformers. Each horizontal line represents a distinct transformer denoted by an index number. The removals and in-service are separated and then ordered by installation date. The horizontal line lengths represent the ages for which each transformer was in the record, that is, how long it was observed after the truncation date. The left end point of each horizontal line is the Enter Age. The vertical red lines are removal ages.

Removal Hazard Function: The hazard function provides the rate of removal. It can be interpreted as the conditional probability of removal in the next unit of time conditioned on surviving up to the beginning of that time unit.

Survival Function: The survival function provide the rate of survival (not being removed). Shows the expected rate of survival per year as the transformer ages. The middle line is the mean value. The top and bottom lines show the 95% confidence limits. The black line is the actual event data survival function calculated using the Kaplan-Meier technique. The Kaplan-Meier technique is an established statistical technique for developing a non-parametric estimate of the survival function based on the observed data.

Yearly Removal Predictions for the Next Five Years: Shows the predicted number of removals of the currently in-service transformers for each of the next five years. The hazard functions has been convoluted with the corresponding in-service population to provide forecasts of anticipated removals.

Cumulative Five Year Removal Predictions: Shows the cumulative predicted number of removals of the currently in-service transformers for next the five years.

115 kV Removal Analysis

The following provides the results of the 115 kV transformer group analyzed using the method described in Chapter 2. Table 3-1 shows the number of transformers in-service and removed from service.

Table 3-1
Transformer Group Data 115 kV

Group	In-service	Removed from Service
115 kV	276	297

Age Demographics 115 kV

Age Demographics In-service 115 kV

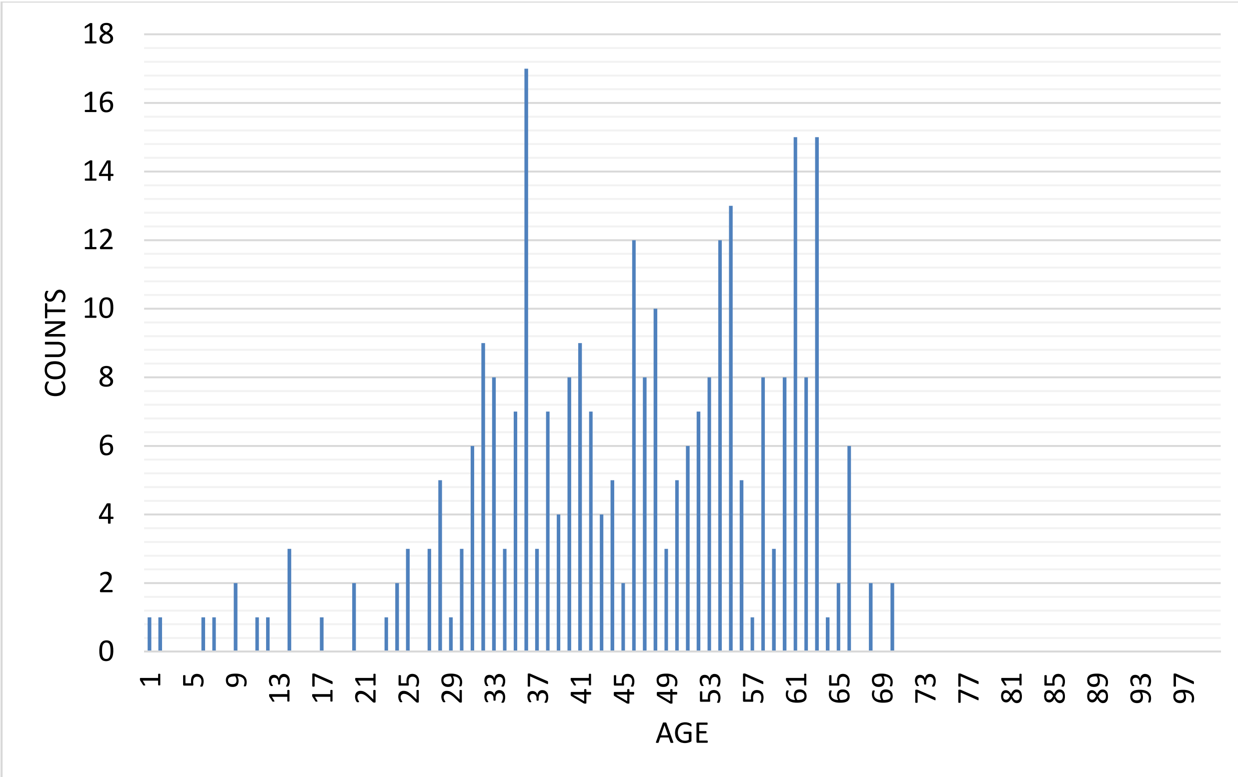

Figure 3-2
Age Demographics Removed From Service 115 kV

Figures 3-3 and 3-4 show the Service Eras and Service Ages of the 115 kV transformer group. The service eras and service ages plots shows the observation period for this transformer group where the observation period began in 1981.

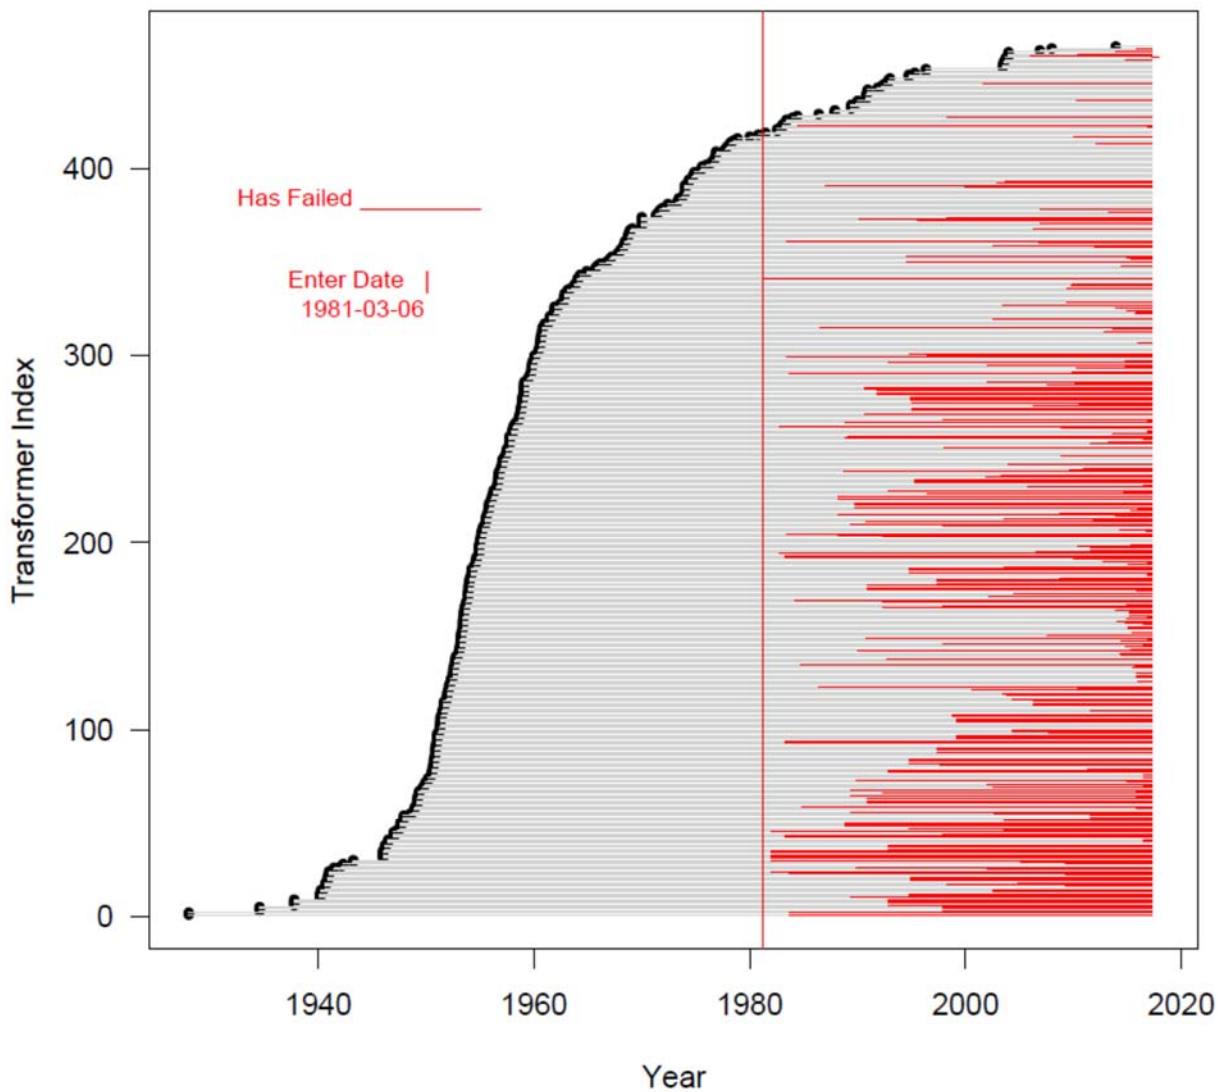

Figure 3-3
Service Eras 115 kV

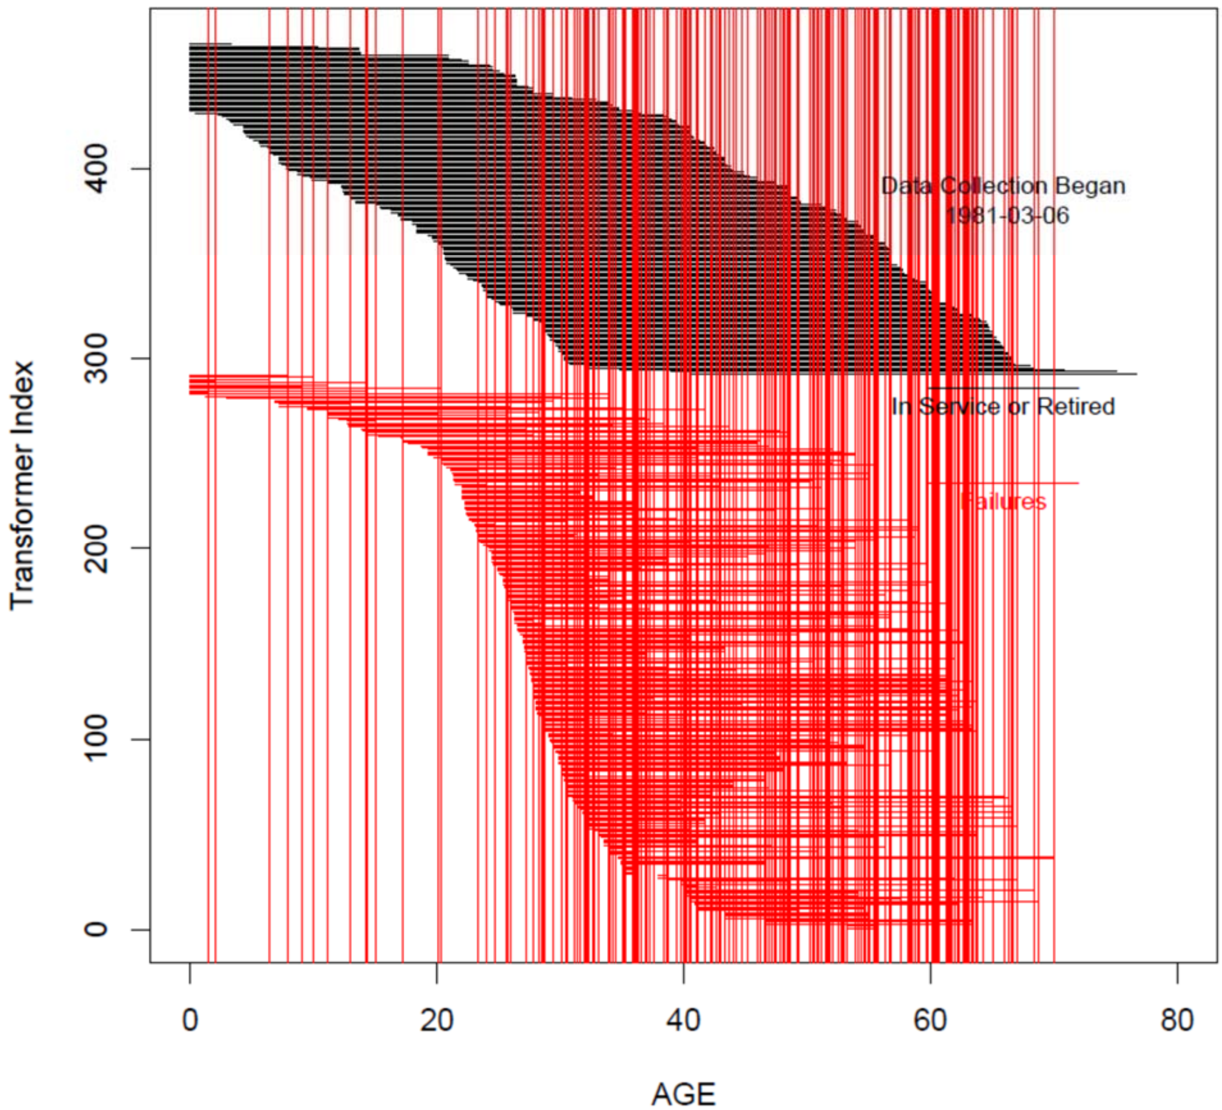

Figure 3-4
Service Ages 115 kV

Removal Hazard Rate 115 kV

Figure 3-5 show the removal rate developed using the in-service and removed from service data provided for the 115 kV transformer. In the figure, probability of a 40 year old transformer being removed in its next year of life ranges from 2.3% to 3%. For a 60 year old transformer the probability of being removed in its next year of life ranges from 4.7% to 6.7%. Note the 95% confidence intervals. The bands become larger above age 60, reflecting the sparse number of recorded removals in these regions.

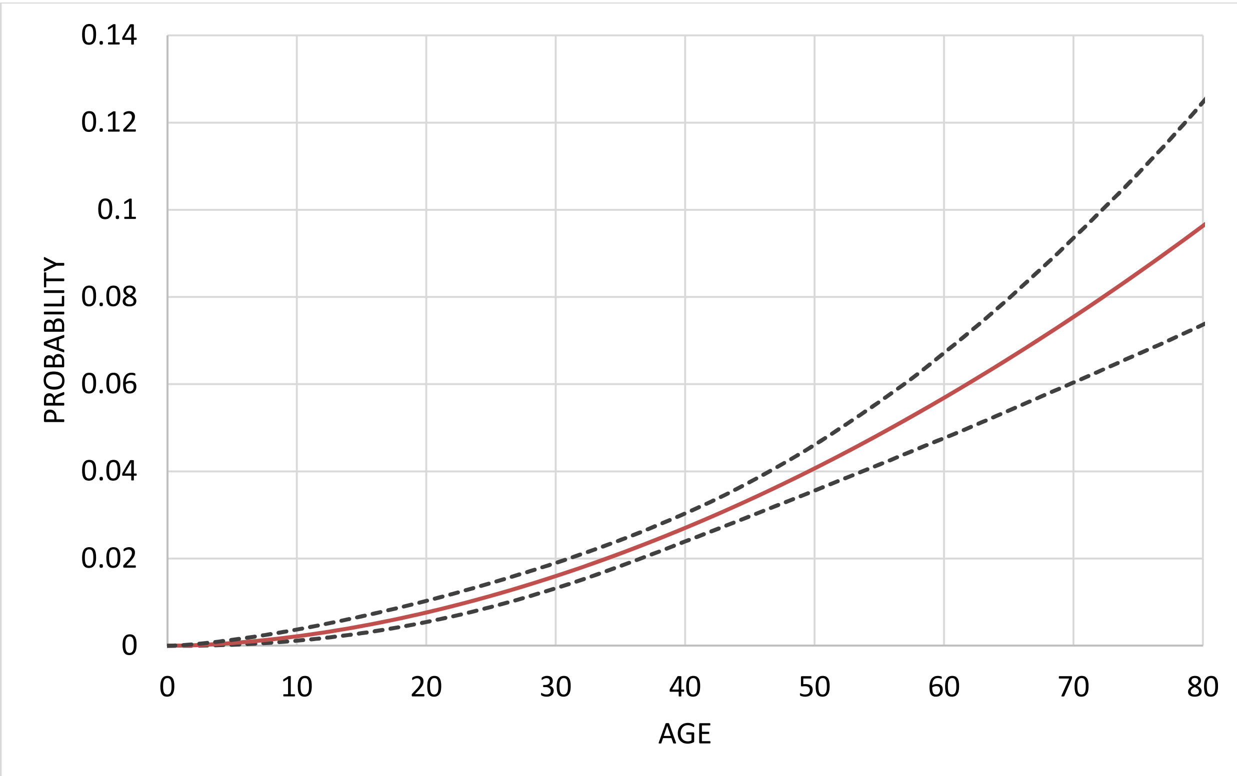

Figure 3-5

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

Derivation of Circuit Breaker Hazard Functions: . EPRI, Palo Alto, CA: 2018. .

EXECUTIVE SUMMARY

A key goal of asset management is to base decisions on an equipment fleet's mean life expectancy. Insights on the fleet mean life expectancy may be derived from careful analysis of historical replacement data. This report describes EPRI work to model and develop circuit breaker removal hazard rates from historical replacement records and apply them to forecast the number of circuit breakers expected to require replacement based on past replacement practices.

EPRI has developed a methodology using advanced statistical techniques for analyzing circuit breaker historical performance and applied it to the Hydro One Networks Inc. transmission circuit breaker fleet. Hydro One Networks Inc. provided in-service and removed from service data for their circuit breaker fleet. Using this data, EPRI developed models for removal rates of circuit breakers as a function of their age. The models along with information about the current fleet were used to project the number of circuit breakers expected to be removed from service over the next five year period assuming past practices are continued to be followed. The results are provided in circuit breaker groups by voltage rating and interrupting mediums.

LIST OF FIGURES

LIST OF TABLES

1
SUPPLIEDCIRCUIT BREAKER DATA

Data Received

Hydro One Networks Inc. (Hydro One) provided the following data as shown in Table 1-1. The circuit breaker fleet has been grouped by voltage rating in kV and interrupting mediums.

Table 1-1
Circuit breaker Group Data

Group	In-service	Removed from Service
13 – 27 kV Air Blast	37	21
13 kV Air Magnetic	251	72
13 – 27 kV Gas	911	163
13 – 27 kV Oil	835	357
13 – 27 kV Vacuum	344	30
44 kV Gas	363	40
44 kV Oil	443	77
115 kV Gas	308	33
115 kV Oil	227	255
230 kV Gas	417	28
230 kV Oil	167	123
230 kV Air Blast	100	99
500 kV Gas	100	4
500 kV Air Blast	47	13

In-service Data

The in-service data provided by Hydro One consists of 4450 Circuit Breakers as of third quarter 2017. The data included the following fields:

- Substation
- Position
- Serial Number
- Manufacturer
- Voltage Rating
- Date Installed
- Age
- Interrupting Medium

Figure 1-1 shows the age demographics of the in-service circuit breaker fleet as of third quarter 2017.

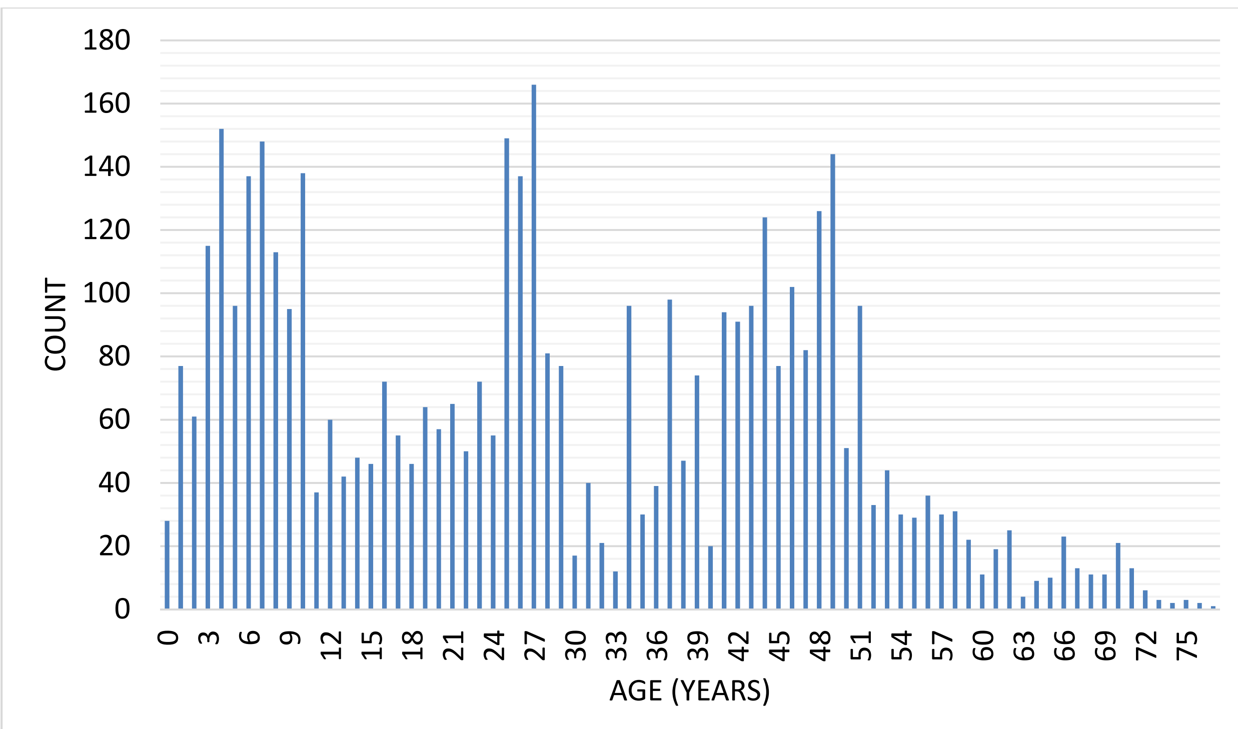

Figure 1-1
In-service Circuit Breaker Age Demographics

Removed from Service Data

The removed from service data provided by Hydro One consists of 1218circuit breakers as of third quarter 2017. No reason for removal was provided. The data included the following fields:

- Substation
- Position
- Serial Number
- Manufacturer
- Voltage Rating
- Date Installed
- Date Removed
- Age
- Interrupting Medium

Figure 1-2 shows the age demographics of the removed from service circuit breakers from the period of 1981 to third quarter 2017.

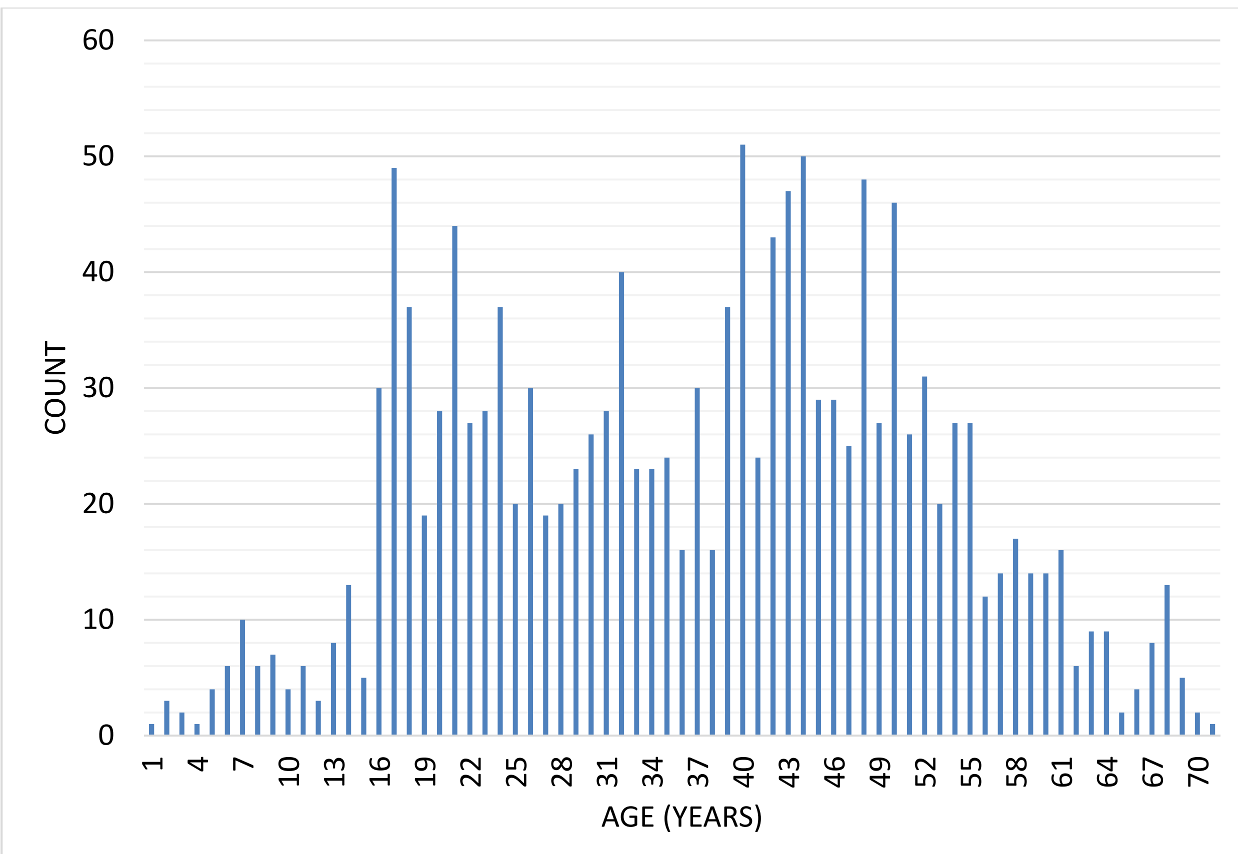

Figure 1-2
Removed from Service Circuit Breaker Age Demographics

2
REMOVAL RATE MODELING

Modeling

EPRI has developed a proven analytic methodology for analyzing circuit breaker event data. The methodology has been demonstrated with a number of utilities' datasets. The modeling methodology assumes a Weibull hazard function for the underlying data described by two parameters, shape and scale. The problem is then to develop the most likely shape and scale values based on the empirical data. A Bayesian approach is utilized.

Analysis began with a "prior distribution" based on the results of EPRI observations of previous utilities circuit breaker data set of in-service and failures. In the Bayesian paradigm, this current knowledge about the model parameters is expressed by placing a probability distribution on the parameters, the prior distribution. As new data, in this case removal observations, becomes available, the information contained regarding the model parameters is expressed in a likelihood, which is proportional to the distribution of the observed data given the model parameters. This information (from removal data) is then combined with the prior distribution to produce a new, upgraded probability distribution formally called the posterior distribution or updated distribution. The calculation involves multidimensional integration of complicated functions and is computationally intense and a Markov Chain Monte Carlo, MCMC, method was used.

The process will be described using the 44 kV oil circuit breaker data as an example. Figure 2-1 is a bivariate plot showing the calculation results for removal for the 44 kV oil circuit breaker population. The blue dots represent a random sample of 9,600 pairs from the updated distribution of shape and scale given the information from the data provide Hydro One. The red ellipse contains the central 95% of the distribution, that is, where most (95%) of the pairs are located. The red dot is the mean of the upgraded Weibull parameter knowledge, the expected shape and scale values. From these upgraded shape and scale parameters removal predictions for currently in-service circuit breakers can be made.

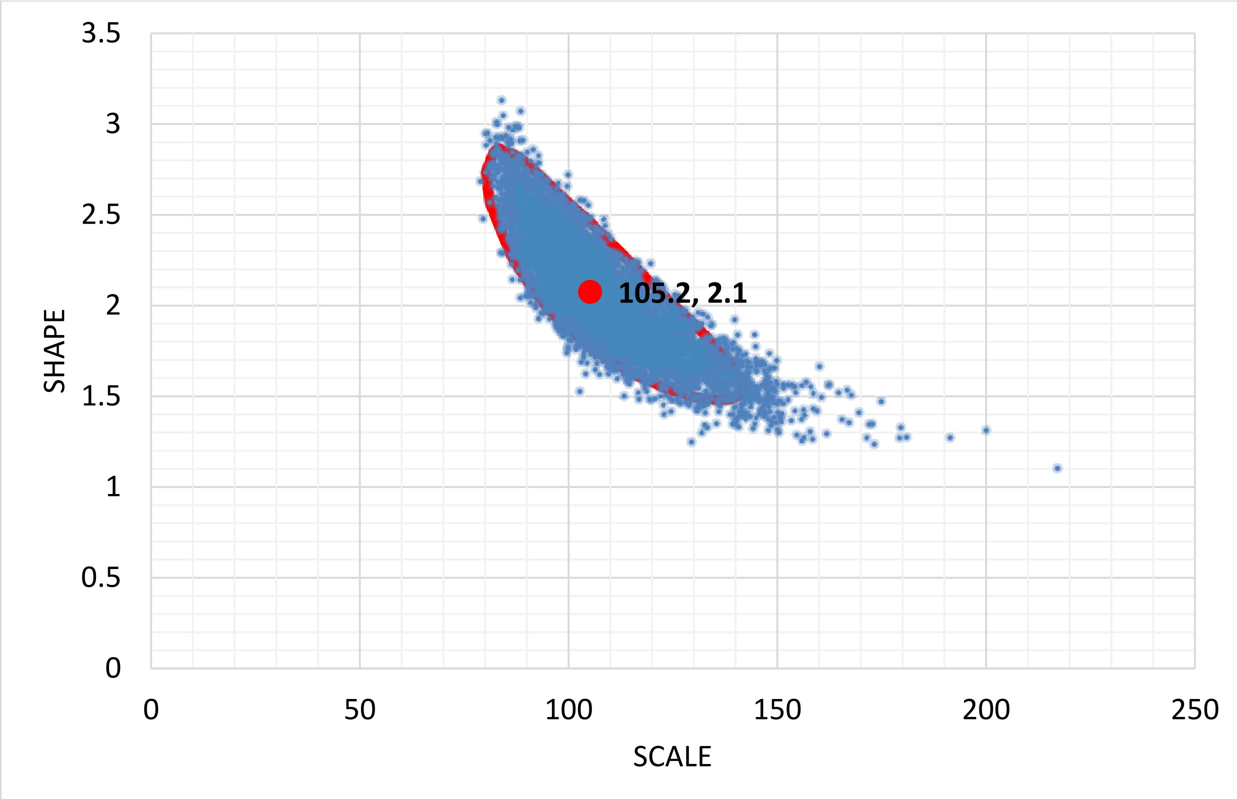

Figure 2-1
Bayesian Result44 kV Oil Circuit breakers

Fitting the data to the Model

The removal rate model is verified by comparing the sample cumulative hazard function calculated from the actual event data (the removals) against the cumulative hazard functions created from the Weibull model. There are cumulative hazard functions for each MCMC observation. For each age from 0 to 100, we calculate the median cumulative hazard rate and the corresponding 95% credibility interval. This calculation provides the median cumulative hazard rate (solid red line) for the model shown in Figure 2-2. The dashed red lines give the 95% credibility interval for these calculations. The black line is the actual event data cumulative hazard function calculated using the Nelson-Aalen technique. The Nelson-Aalen technique is an established statistical technique for developing a non-parametric estimate of the cumulative hazard function based on the observed data.

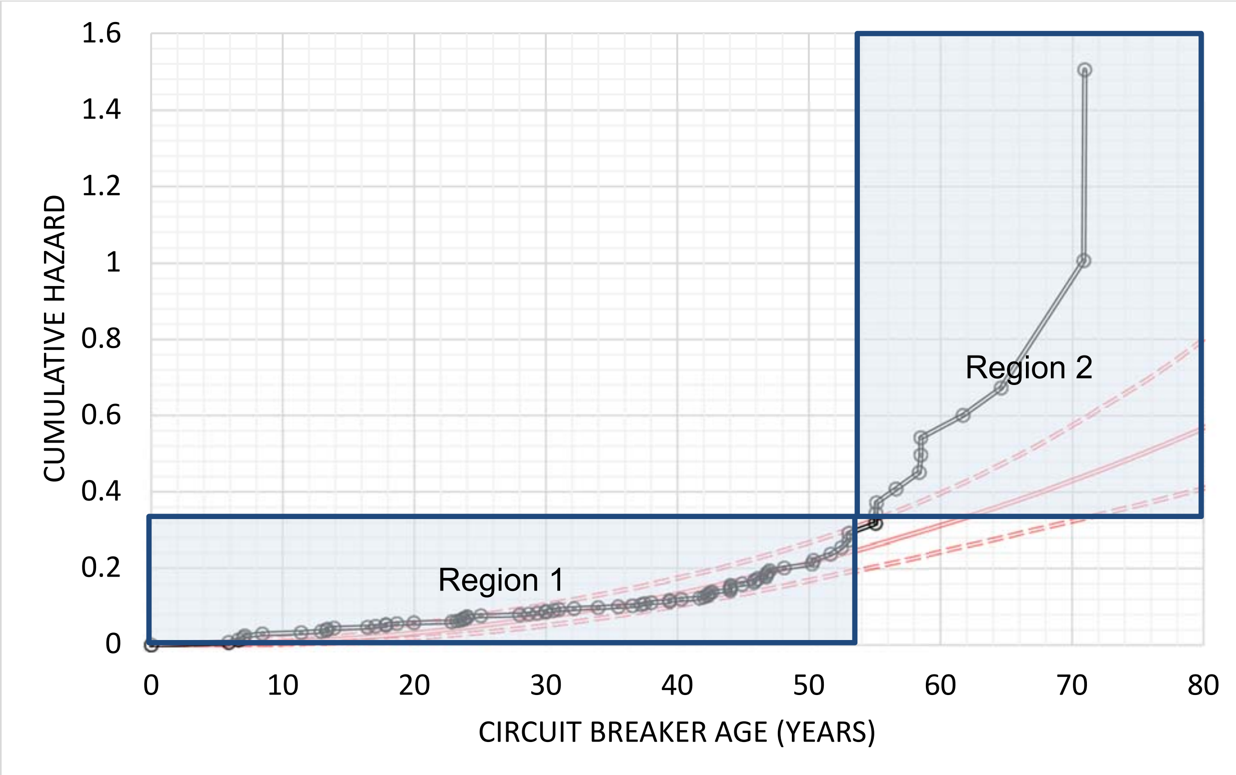

Figure 2-2
Comparison of Model and Sample Cumulative Hazard Functions44kV Oil Circuit breakers

Figure 2-2 for the 44 kV oil circuit breaker group show two regions with different levels of agreement between the red and black lines. A good Weibull model fit for most of the life (Region 1) and a much steeper replacement rate (black line) than provided by the Weibull model in later life (Region 2). However, younger power circuit breakers are rarely replaced except for failure. Therefore, Region 1 may be a reasonable model for the failure hazard rate. The transition point between the two regions could indicate the following:

- The onset of a failure process that is more dominant in older units.
- The result of discretionary replacement decisions.
- Some combination of both failure process and discretionary replacement.

Since the reasons for removal are not noted, failures and discretionary replacements cannot be distinguished.

Modeling Assumptions

- The starting data is complete and contains all removals and in-service units for the period within 1982 through third quarter 2017.
- The criteria for removal have been constant over the historical period being analyzed.

- Future criteria for removals will be the same as in the past.
- Any external effects on removal rates (e.g. budget constraints) were constant over the historical period and will be unchanged over the forecast period.
- Underlying wear-out processes will not change.
- It is important to note that the hazard rate function derived is for removals, not failures.

Modeling Results

There are currently 443 circuit breakers in service of various ages in the 44 kV oil group. Based on the age of each individual circuit breaker, the distributions of the number of removals was predicted from a Monte Carlo simulation.

Each of the 9,600 pair results from the analyses results (Figure 2-1) is used in a Monte Carlo simulation to generate the expected number of removals. Each shape and scale pair defines a Weibull distribution. This distribution is applied to each of the in-service circuit breakers and the number of removals are summed for the total population for that particular distribution.

The resulting histogram of the sum of the number of removals recorded in each plot (Figure 2-3) gives the probability distribution of removals. The entire process is then repeated for the next year with each circuit breaker's age incremented by one.

Figure 2-3 shows the predicted number of removals of the currently in-service circuit breakers for each of the next five years and the five year total.

The figure can be interpreted as probability distributions. For example, in the plot for year 1, adding up the probabilities corresponding to 0 through 8 removals, we can say that we are 99% certain that the number of circuit breaker removals will be 8 or fewer.

3
REMOVAL ANALYSIS RESULTS

Using the data provided by Hydro One described in Chapter 1. The following chapter provides the results of the application of the model describe in Chapter 2 for each of the circuit breaker groupings.

Each group results will include the following plots:

In-service Age Demographics: Shows the age distribution in years for the specific circuit breaker group.

Removed from Service: Shows the age distribution in years for the specific circuit breaker group.

Service Eras: Provides information about the completeness of the data set. The horizontal axis is in years. Each horizontal line represents a circuit breaker recorded. The black lines show the installation dates. If a line is gray, the circuit breaker is still in service. If a line turns red, the circuit breaker has been removed from service on the date of the color change.

Service Ages: Provides information about the completeness of the data set. The horizontal axis is the age of the circuit breakers. Each horizontal line represents a distinct circuit breaker denoted by an index number. The removals and in-service are separated and then ordered by installation date. The horizontal line lengths represent the ages for which each circuit breaker was in the record, that is, how long it was observed after the truncation date. The left end point of each horizontal line is the Enter Age. The vertical red lines are removal ages.

Removal Hazard Function: The Weibull model hazard function provides the rate of removal. It can be interpreted as the conditional probability of removal in the next unit of time conditioned on surviving up to the beginning of that time unit.

Survival Function: The survival function derived from the Weibull model provides the rate of survival (not being removed).Shows the expected rate of survival per year as the circuit breaker ages. The middle line is the mean value. The top and bottom lines show the 95% confidence limits. The black line is the actual event data survival function calculated using the Kaplan-Meier technique. The Kaplan-Meier technique is an established statistical technique for developing a non-parametric estimate of the survival function based on the observed data.

Yearly Removal Predictions for the Next Five Years: Shows the predicted number of removals of the currently in-service circuit breakers for each of the next five years. The hazard functions has been convoluted with the corresponding in-service population to provide forecasts of anticipated removals.

Cumulative Five Year Removal Predictions: Shows the cumulative predicted number of removals of the currently in-service circuit breakers for next the five years.

13 – 27 kV Air Removal Analysis

The following provides the results of the 13 – 27 kV air blast circuit breaker group analyzed using the method describe in Chapter 2. Table 3-1 shows the number of circuit breakers in-service and removed from service.

Table 3-1
Circuit breaker Group Data 13 – 27 kV Air Blast

Group	In-service	Removed from Service

Service Ages 13 – 27 kV Air Blast

Removal Hazard Rate13 – 27 kV Air Blast

Figure 3-5 shows the removal rate developed using the in-service and removed from service data provided for the 13 – 27 kV Air Blast circuit breaker. In the figure, probability of a 20 year old circuit breaker being removed in its next year of life ranges from 0.6% to 2.3%. For a 40 year old circuit breaker the probability of being removed in its next year of life ranges from 1.1% to 2.8%.

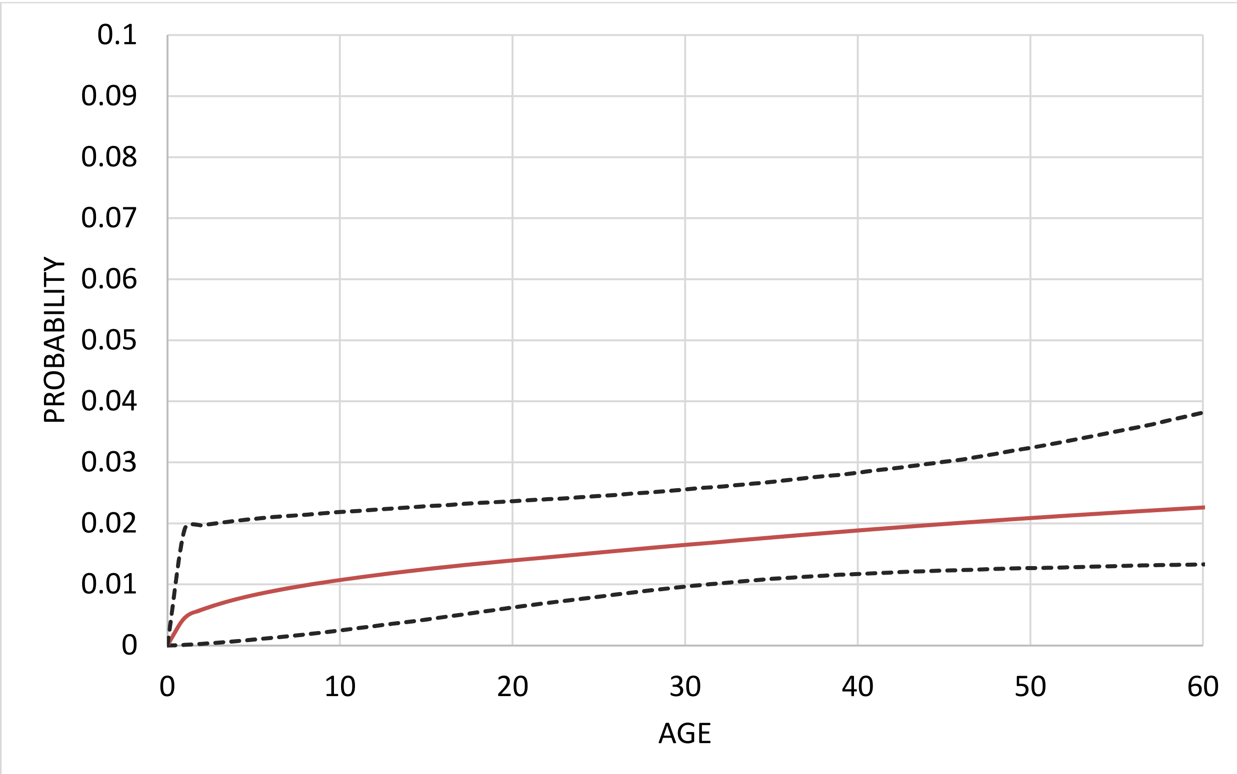

Figure 3-5
Removal Hazard Rate 13 – 27 kV Air Blast

Survival Function 13 – 27 kV Air Blast

Figure 3-6 shows the survival function developed using the in-service and removed from service data provided for the 13 – 27 kV Air Blast circuit breaker group. In the figure, the mean probability of a 40 year old circuit breaker surviving (not being removed) in its next year of life ranges from 38% to 77%.

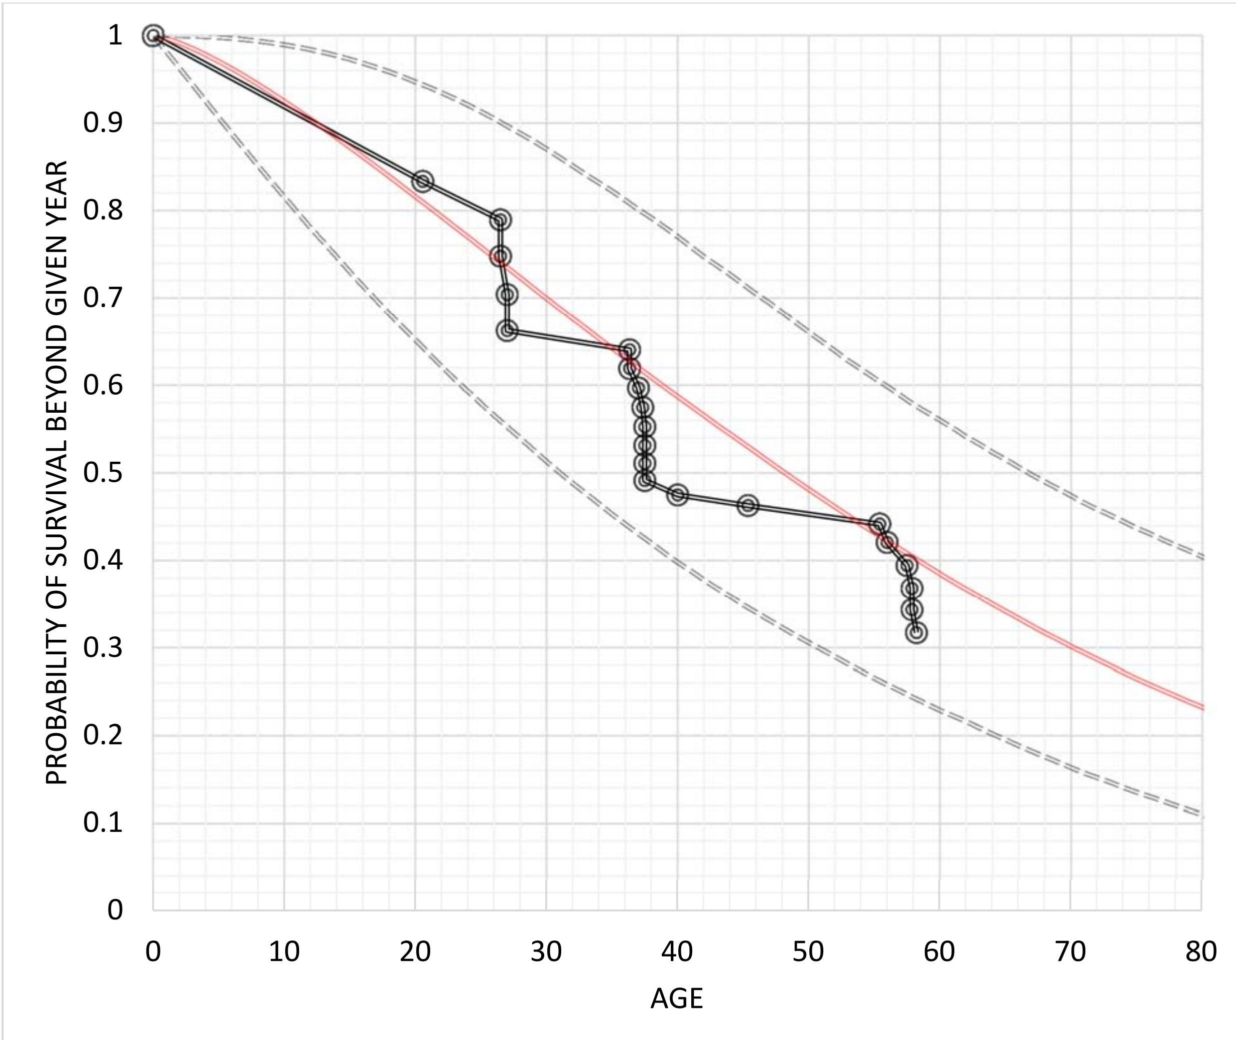

Figure 3-6
Survival Function 13 – 27 kV Air Blast

Forecasting Removals

Figures 3-7 and 3-8 show the predicted number of circuit breaker removals for each of the next five years. The predicted number of removals for each year are and five year total shown in Figure 3-7. For example, in the plot for year 1, adding up the probabilities corresponding to 0 through 3 removals, we can say that we are 99% certain that the number of circuit breaker removals will be 3 or fewer. Figure 3-8 presents the cumulative results combining each year of the five year period.

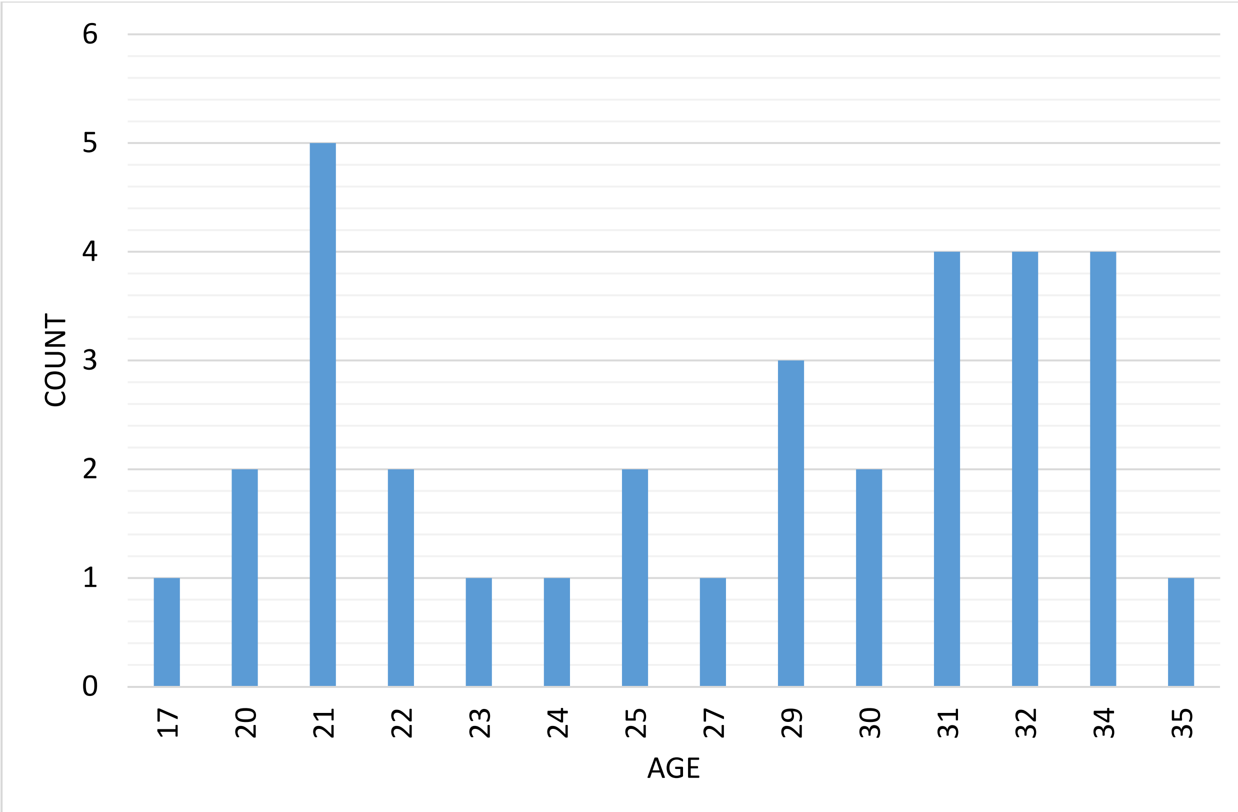

Figure 3-50
Age Demographics Removed From Service 115 kV Gas

Figures 3-51 and 3-52 show the Service Eras and Service Ages of the 115 kV Gas circuit breaker group. The service eras and service ages plots shows the observation period for this circuit breaker group where the observation period began in 1999.

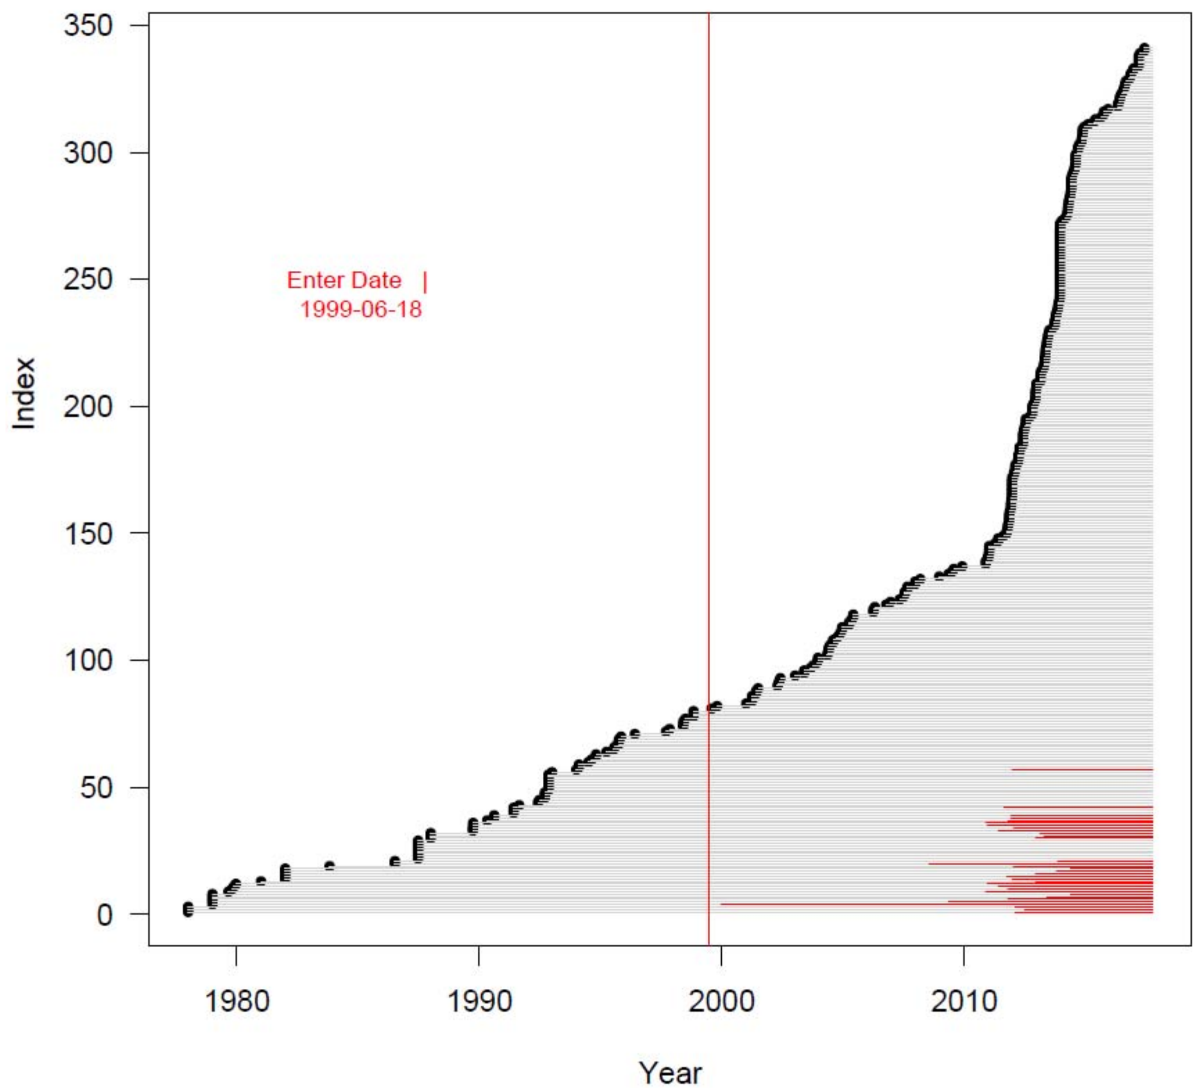

Figure 3-51
Service Eras 115 kV Gas

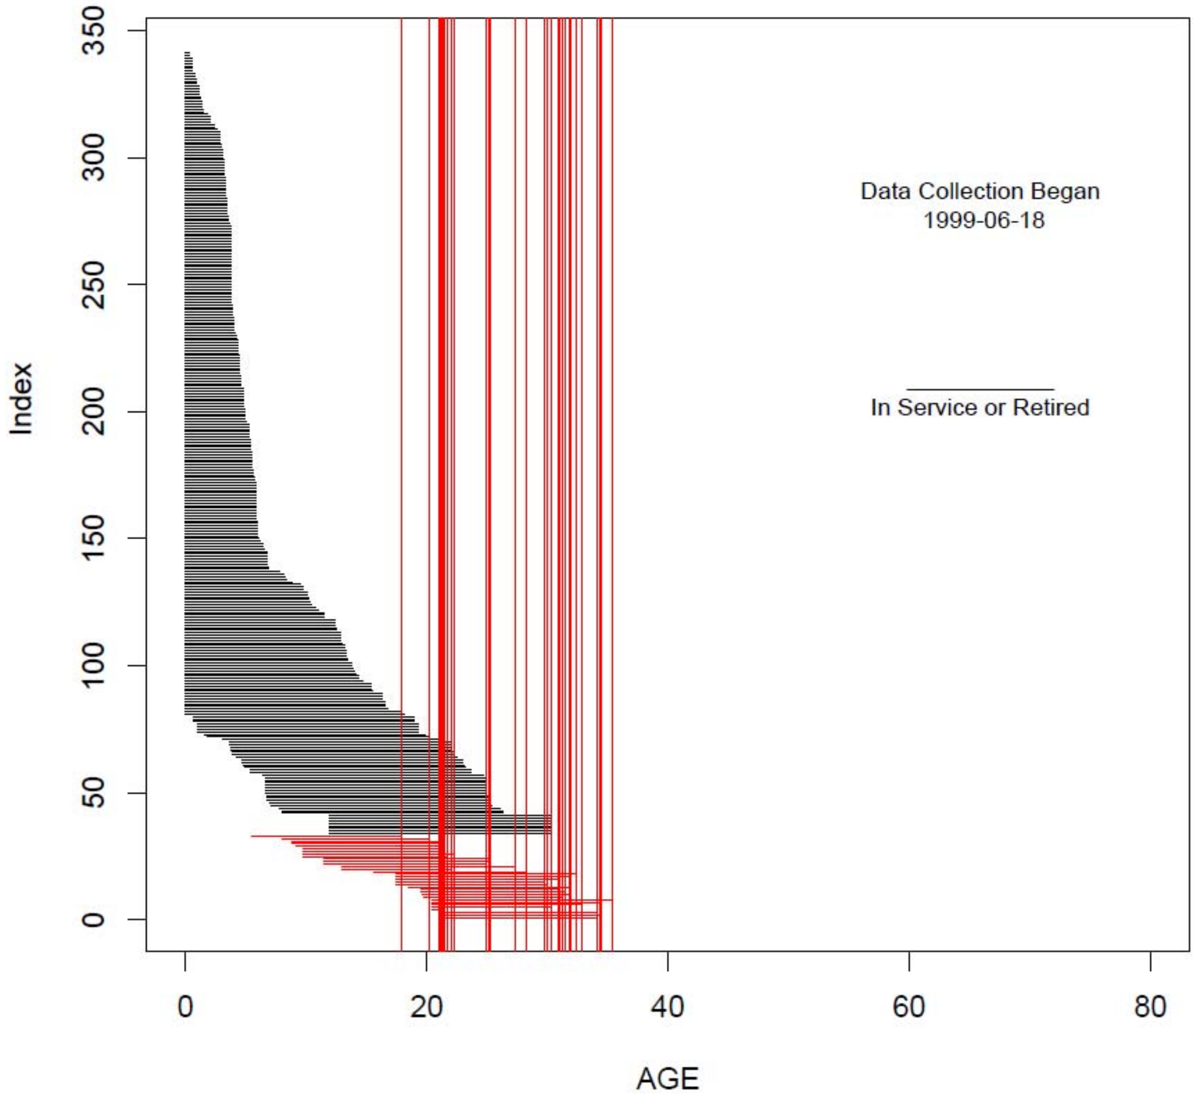

Figure 3-52
Service Ages 115 kV Gas

Removal Hazard Rate 115 kV Gas

Figure 3-53 shows the removal rate developed using the in-service and removed from service data provided for the 115 kV Gas circuit breaker. In the figure, probability of a 40 year old circuit breaker being removed in its next year of life ranges from 12% to 26%. For a 50 year old circuit breaker the probability of being removed in its next year of life ranges from 23% to 51%. Note the 95% confidence intervals. The bands become larger above age 50, reflecting the sparse number of recorded removals in these regions.

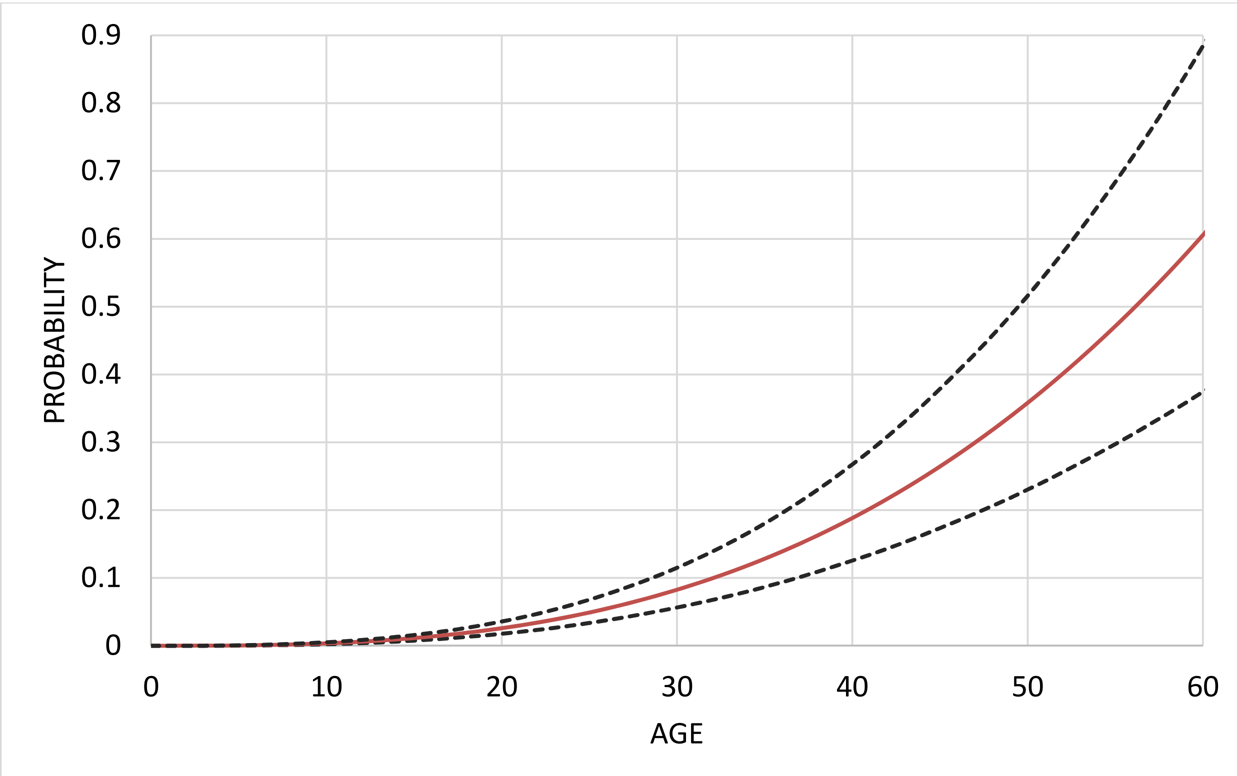

Figure 3-53
Removal Rate 115 kV Gas

Survival Function 115 kV Gas

Figure 3-54 shows the survival function developed using the in-service and removed from service data provided for the 115 kV Gas circuit breaker group. In the figure, the mean probability of a 40 year old circuit breaker surviving (not being removed) in its next year of life ranges from 6.5% to 26%.

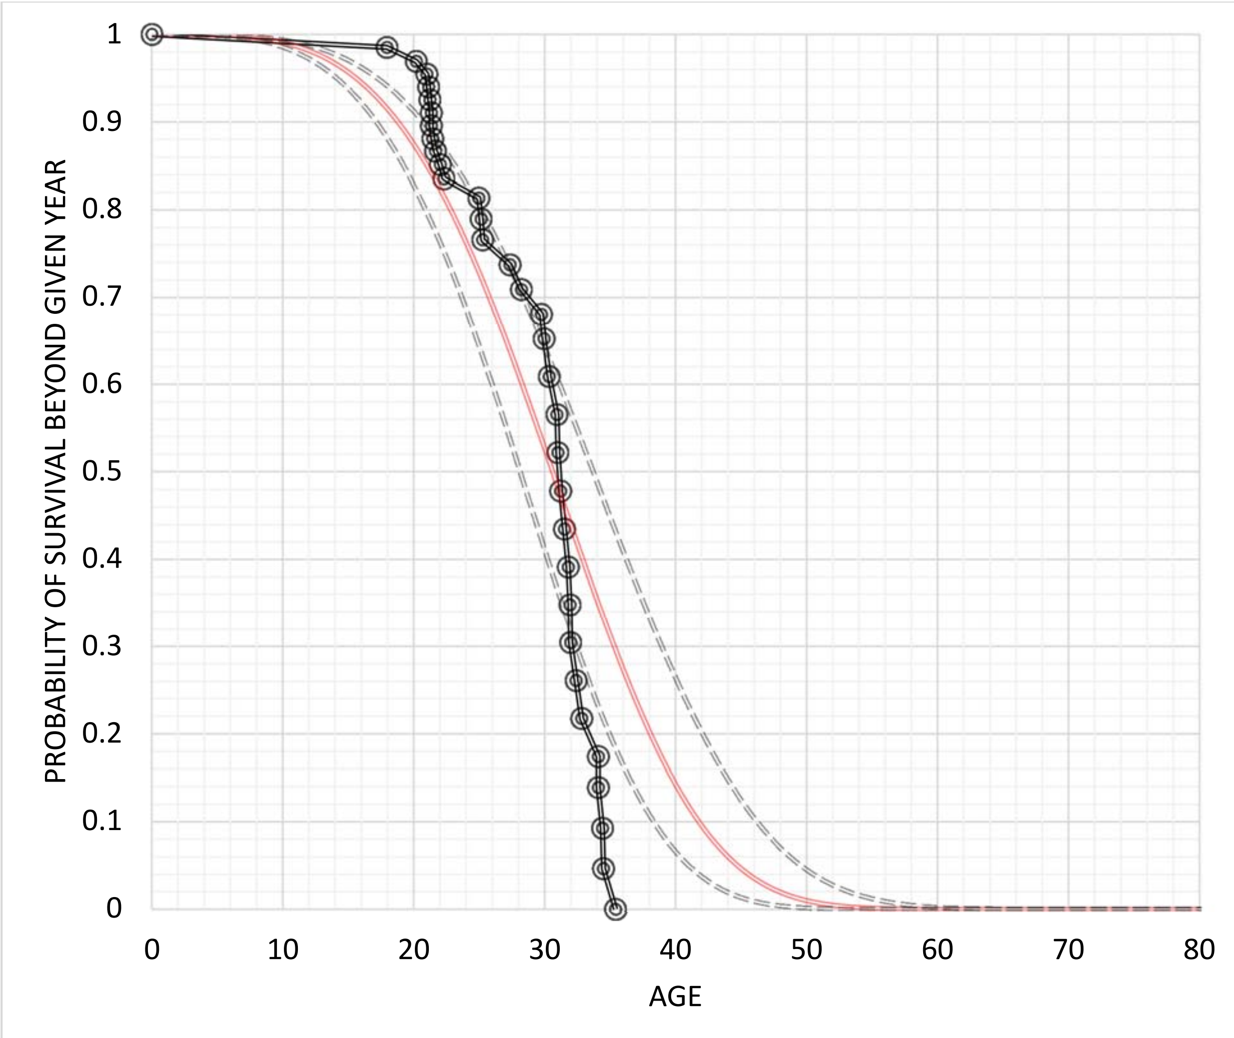

Figure 3-54
Survival Function 115 kV Gas

Forecasting Removals

Figures 3-55 and 3-56 show the predicted number of circuit breaker removals for each of the next five years. The predicted number of removals for each year are and five year total shown in Figure 3-55. For example, in the plot for year 1, adding up the probabilities corresponding to 0 through 6 removals, we can say that we are 99% certain that the number of circuit breaker removals will be 6 or fewer. Figure 3-56 presents the cumulative results combining each year of the five year period.

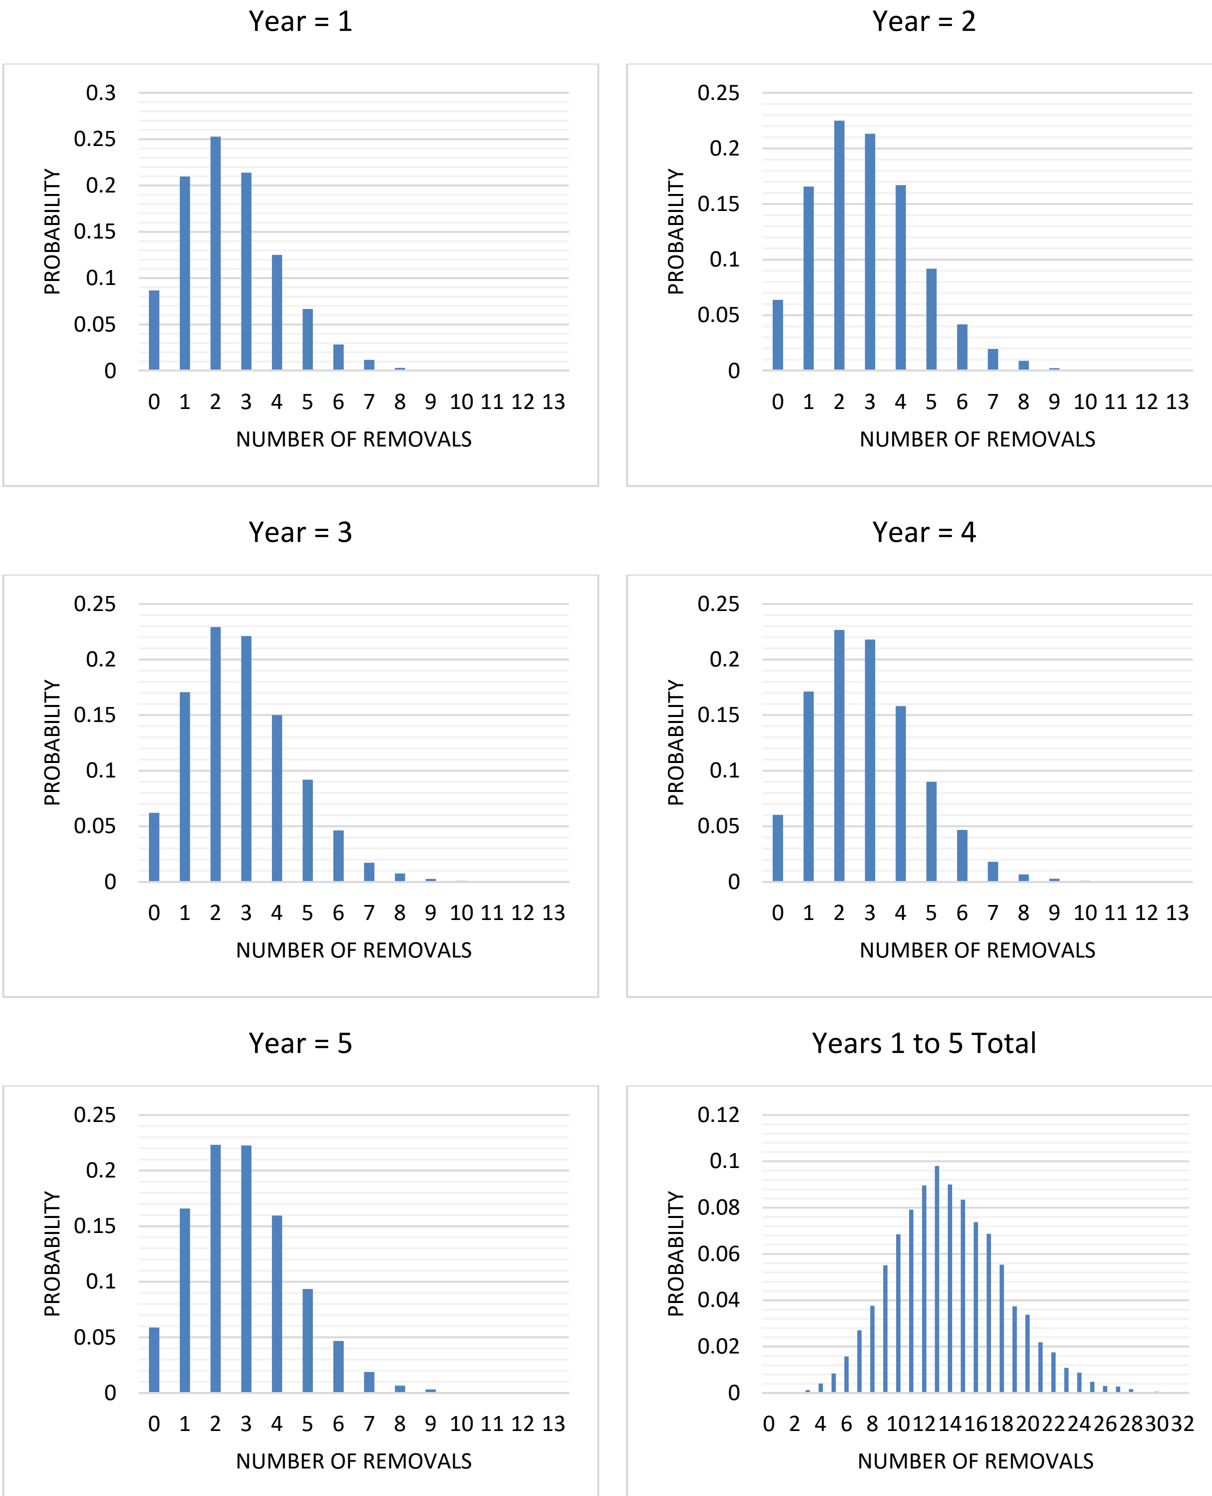

Figure 3-55

Cumulative Probability of In-Service Circuit breaker Removals Next Five Years 115 kV Gas

115 kV Oil Removal Analysis

The following provides the results of the 115 kV Oil circuit breaker group analyzed using the method describe in Chapter 2. Table 3-8 shows the number of circuit breakers in-service and removed from service.

Table 3-8
Circuit breaker Group Data 115 kV Oil

Group	In-service	Removed from Service
115 kV Oil	227	255

Age Demographics 115 kV Oil

Figures 3-57 and 3-58 show the age demographics for both in service and removed from service circuit breaker units.

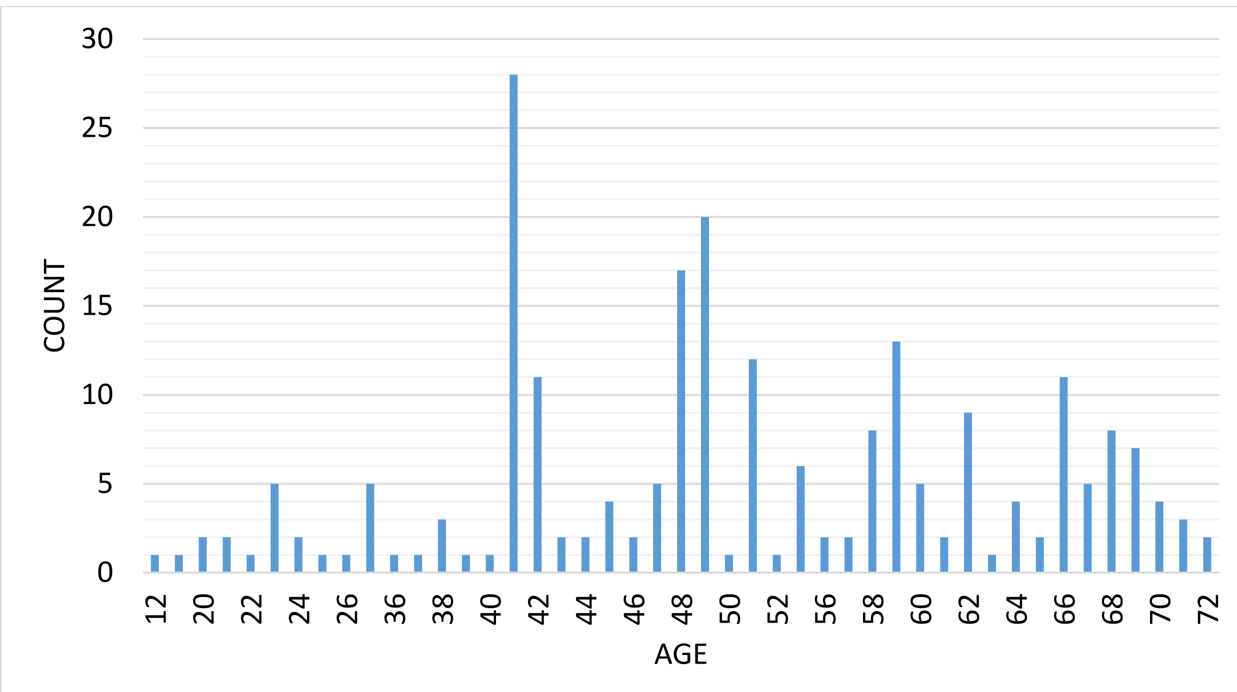

Figure 3-57
Age Demographics In-service 115 kV Oil

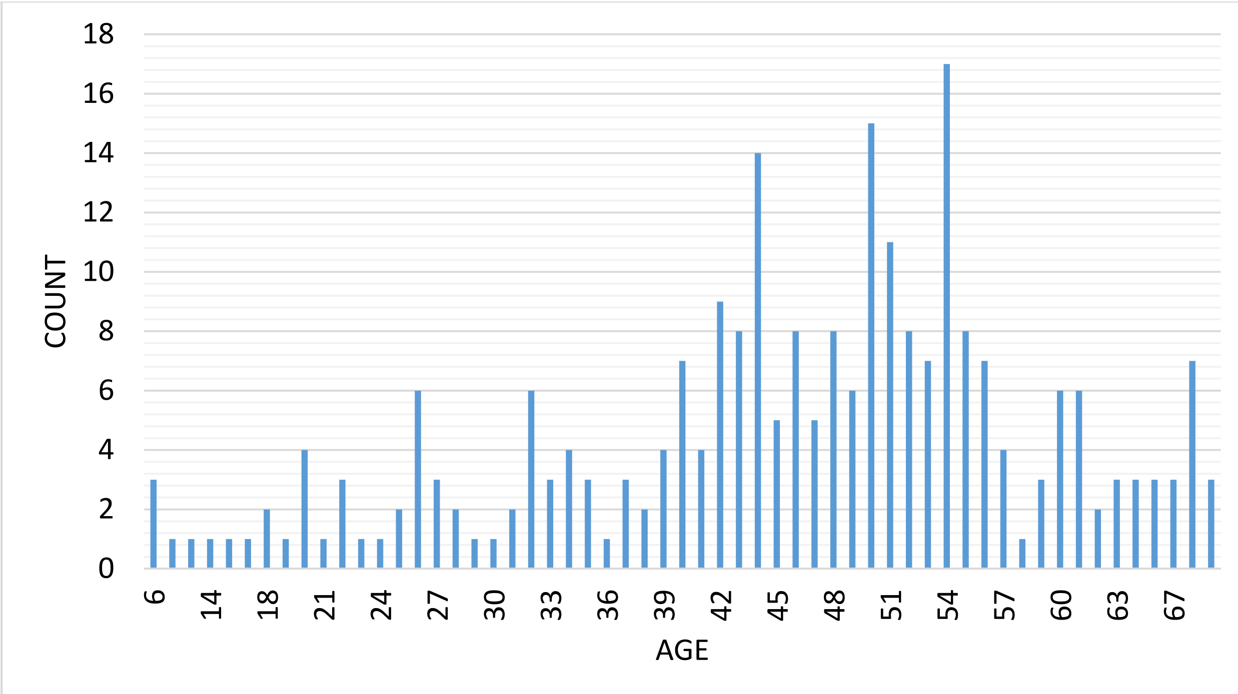

Figure 3-58
Age Demographics Removed From Service 115 kV Oil

Figures 3-59 and 3-60 show the Service Eras and Service Ages of the 115 kV Oil circuit breaker group. The service eras and service ages plots shows the observation period for this circuit breaker group where the observation period began in 1985. The relatively large number of breakers removed before age 20 suggests that these removals may have been for some unusual and potentially one-off reason. Therefore, the model results may be unnecessarily pessimistic.

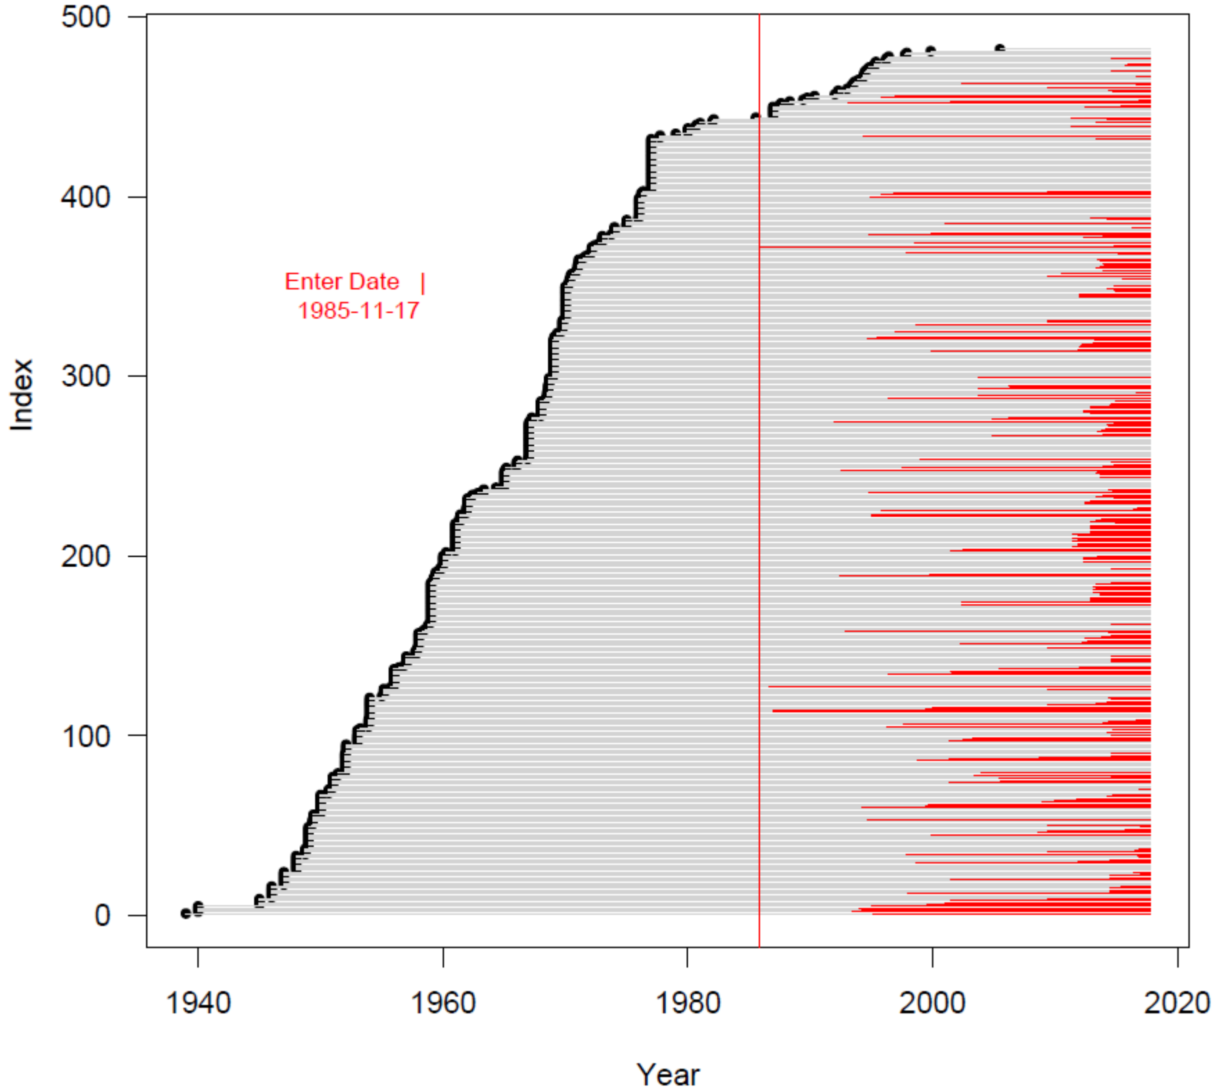

Figure 3-59
Service Eras 115 kV Oil

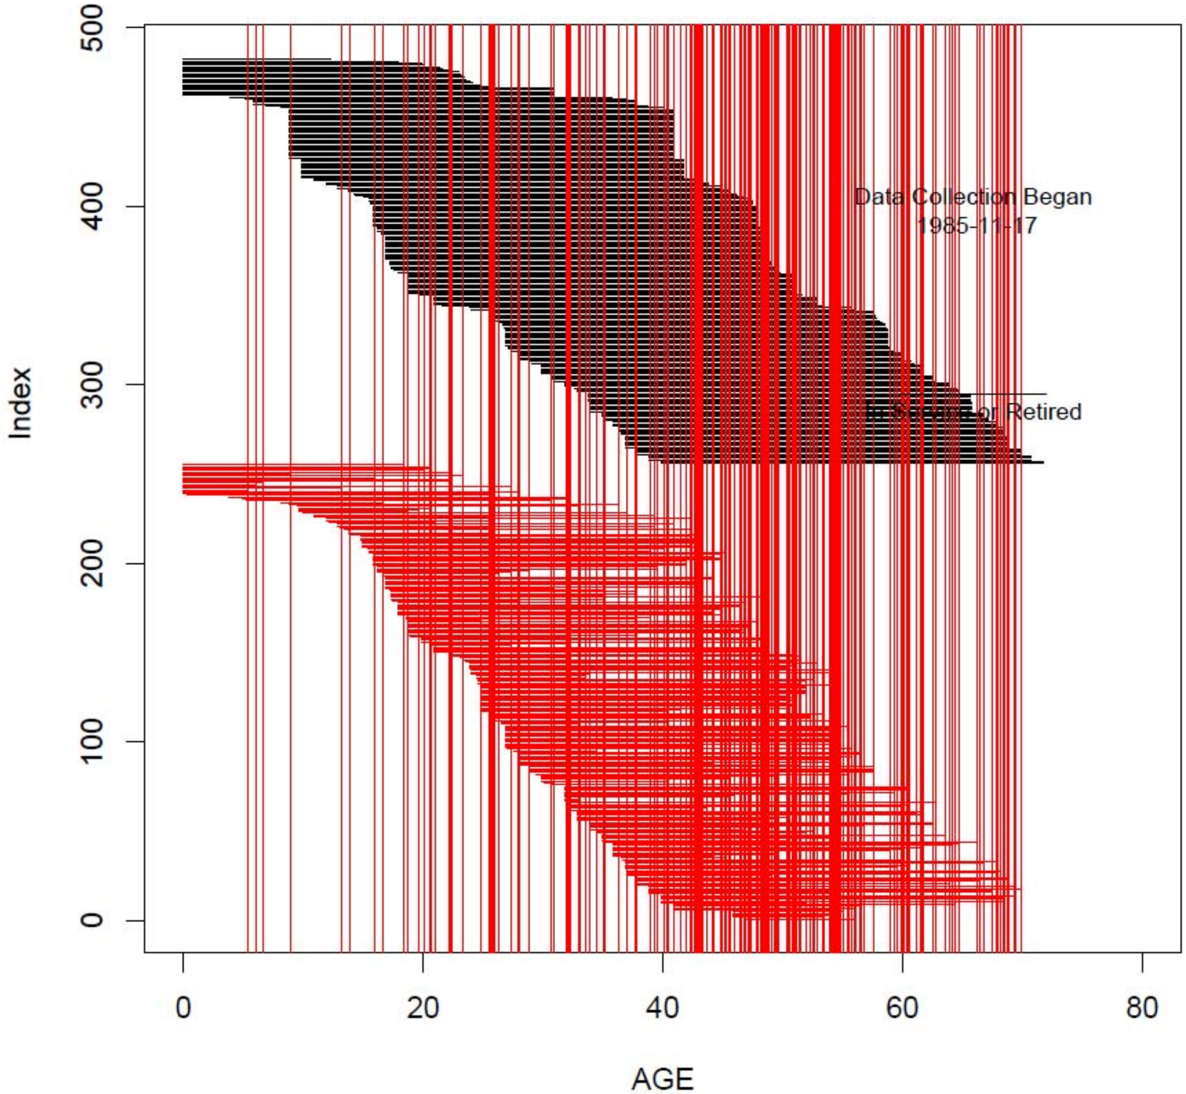

Figure 3-60
Service Ages 115 kV Oil

Removal Hazard Rate 115 kV Oil

Figure 3-61 shows the removal rate developed using the in-service and removed from service data provided for the 115 kV Oil circuit breaker. In the figure, probability of a 40 year old circuit breaker being removed in its next year of life ranges from 2.3% to 2%. For a 60 year old circuit breaker the probability of being removed in its next year of life ranges from 3.9% to 5.6%. Note the 95% confidence intervals. The bands become larger above age 70, reflecting the sparse number of recorded removals in these regions.

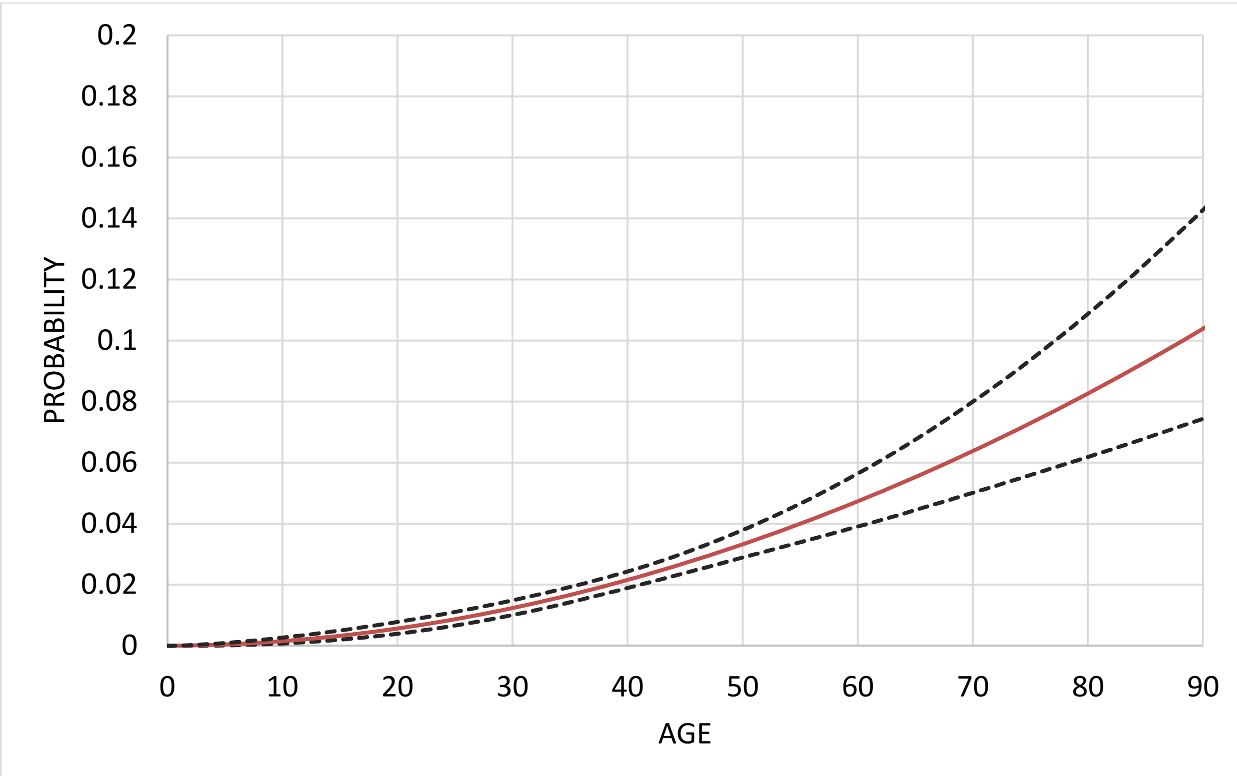

Figure 3-61
Removal Rate 115 kV Oil

Survival Function 115 kV Oil

Figure 3-62 shows the survival function developed using the in-service and removed from service data provided for the 115 kV Oil Air circuit breaker group. In the figure, the mean probability of a 40 year old circuit breaker surviving (not being removed) in its next year of life ranges from 71% to 78%.

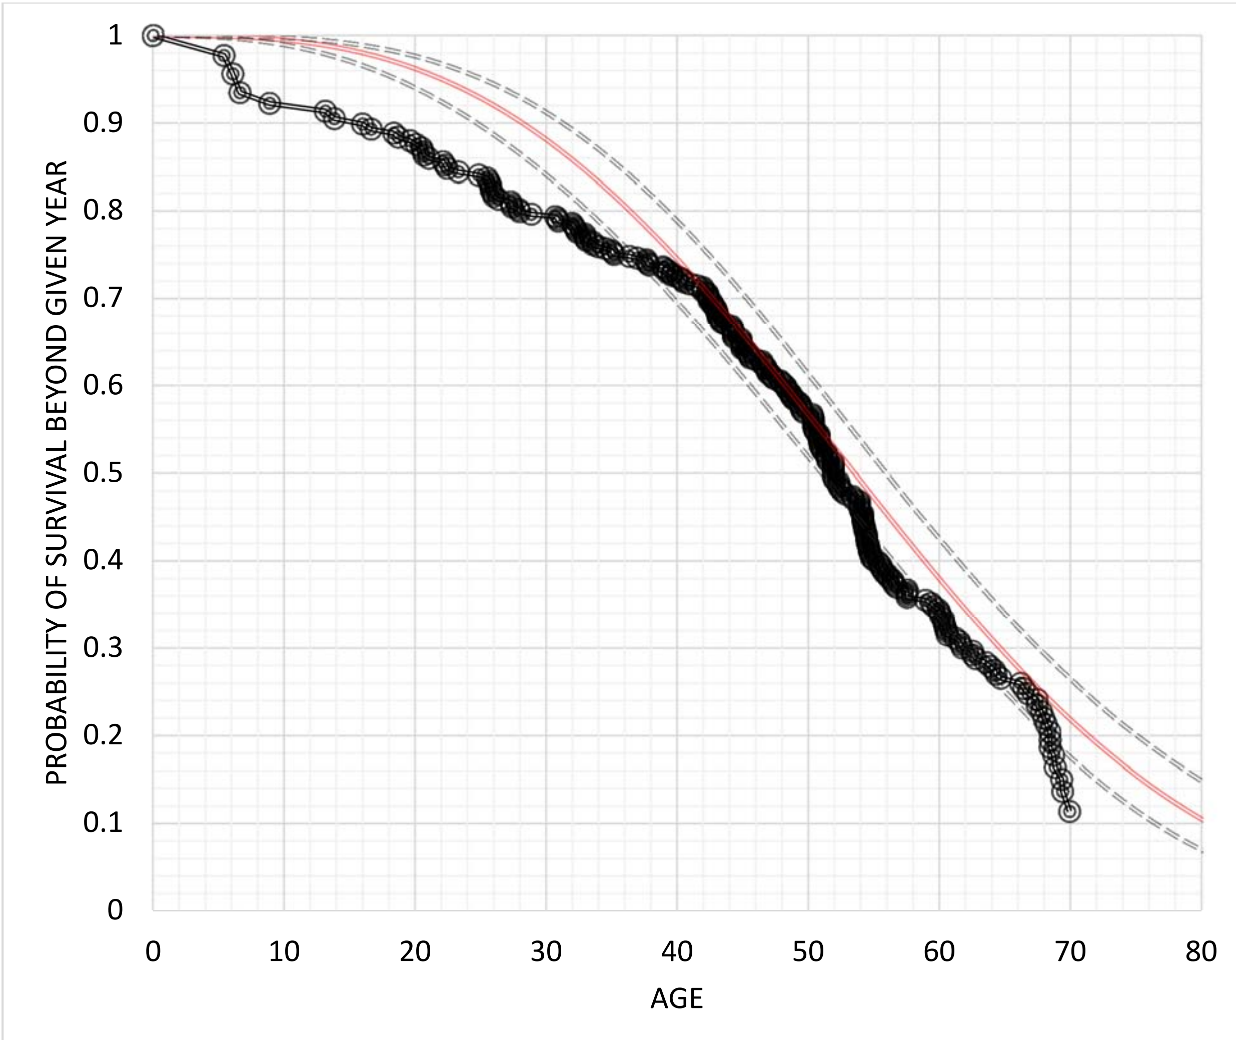

Figure 3-62
Survival Function 115 kV Oil

Forecasting Removals

Figures 3-63 and 3-64 show the predicted number of circuit breaker removals for each of the next five years. The predicted number of removals for each year are and five year total shown in Figure 3-63. For example, in the plot for year 1, adding up the probabilities corresponding to 0 through 14 removals, we can say that we are 99% certain that the number of circuit breaker removals will be 14 or fewer. Figure 3-64 presents the cumulative results combining each year of the five year period.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc.(EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

Derivation of Overhead Conductor Hazard Function. EPRI, Palo Alto, CA: 2018.

EXECUTIVE SUMMARY

A key goal of asset management is to base decisions on equipment's fleet mean life expectancy. Insights on the fleet mean life expectancy may be derived from careful analysis of historical condition assessment and replacement data. This report describes EPRI work to develop a replacement hazard rate and apply it to forecast the amount in kilometers of Aluminum Conductor Steel Reinforced (ACSR) overhead transmission conductor expected to require replacement based on past assessments and replacements.

EPRI has developed a methodology using advanced statistical techniques for analyzing conductor historical replacements and assessments and applied it to the Hydro One Networks Inc. overhead ACSR transmission conductor fleet.

Hydro One provided in-service and removed-from-service data for their overhead ACSR transmission conductor fleet. Using this data, EPRI developed a mathematical model relating ACSR conductor age to the probability that an ACSR conductor would be in a condition warranting removal. The model, along with demographic information about the current fleet, was used to project the amount in kilometers of ACSR conductors expected to be in a state warranting removal from service over the next five, ten and twenty-year periods.

1 INTRODUCTION AND BACKGROUND

Introduction

Hydro One Networks Inc., like many utilities, is striving to maintain the reliability of its transmission network while controlling maintenance, repair and replacement costs. Aging equipment, more stringent operating requirements, financial constraints and retiring expertise have made the management of transmission line assets increasingly challenging.

To address these challenges, Hydro One is reviewing its maintenance and replacement practices to ensure they are underpinned by sound evidence. This includes the use of condition and risked-based maintenance and replacement scheduling using advanced analytics-based techniques. Understanding the condition and remaining life of conductors would help transmission asset managers make better decisions about conductor maintenance, repair, and replacement.

As part of this asset management effort, Hydro One asked EPRI to investigate available Hydro One overhead transmission line conductor demographic and condition data and determine what insights could be obtained to support asset management decisions.

This report describes the EPRI investigation.

Background

Hydro One's service territory is the size of Texas plus California, and driving across it can take three days. Most of the province's population is concentrated along the southeastern border far from hydroelectric generating stations. Long transmission circuits as well as widely distributed substations are required to deliver power over these distances. These transmission and distribution assets are exposed to environmental stresses, including severe weather and temperature variations that can degrade equipment over time.

Hydro One defines Expected Service Life (ESL) as the average age in years that an asset can be expected to operate under normal system conditions. Half of the assets are expected to operate beyond this ESL. Hydro One also defines End of Life (EOL) as the state of having a high likelihood of failure, or loss of an asset's ability to provide the intended functionality as determined through diagnostic data, wherein the failure or loss of functionality would cause unacceptable consequences. EOL is always determined by condition assessment.

One asset of interest, and the focus of this report, is Hydro One's overhead transmission line conductor fleet. Hydro One's estimated ESL for conductors is approximately age 70. Based on past experience, condition assessments are not conducted before 50 years of age. As shown in Figure 1-1, many of the fleet conductor assets are beyond their presently used ESL.

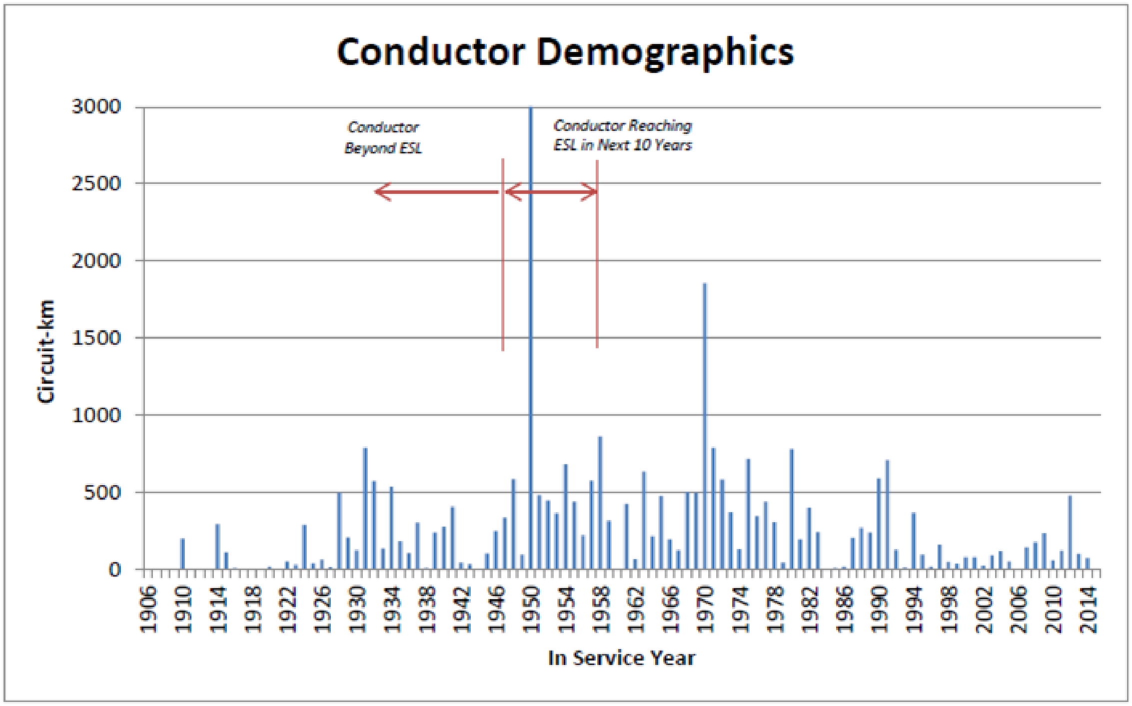

Figure 1-1
Hydro One Conductor Fleet Demographics. 19% of conductors are beyond their expected service life (ESL). In 10 years, 42% will be beyond ESL. (Data source: Hydro One)

Objectives

The project objectives were to investigate data provided by Hydro One Networks Inc. on conductor historical replacements and assessments, along with their in-service overhead transmission conductor fleet, and determine what insights could be obtained to support asset management decisions.

The analysis focused on Aluminum Conductor Steel Reinforced (ACSR) samples. An example is shown in Figure 1-2.

Figure 1-2
Aluminum Conductor Steel Reinforced (ACSR 26/7 Drake)

Approach

The EPRI work plan for this project had the following components:

- Review and gain familiarity with the ACSR conductor condition assessment data provided by Hydro One
- Investigate the feasibility of using the data for conductor life analysis
- Develop a methodology using advanced statistical techniques for analyzing conductor historical replacements and assessments
- Apply the developed methodology to the Hydro One ACSR conductor condition assessment data as well as in-service and removed-from-service data for their overhead ACSR transmission conductor fleet
- Project the amount in kilometers of ACSR overhead transmission conductors expected to be in a state warranting removal from service over the next five, ten and twenty year periods based on the assessment data and the replacements data

Report Organization

The report contains the following chapters:

Chapter 1: Introduction and Background

Chapter 2: Description of the Data

Chapter 3: Exploratory Analyses on Conductor Condition Assessment Data

Chapter 4: Modeling of Assessed Condition as a Function of Age

Chapter 5: Discussion and Applications of Modeling Results

Chapter 6: Conclusions

2
DESCRIPTION OF THE DATA

Introduction

Data Sets

Conductor data was organized into two principal sets:

1) Conductor condition assessment data. This data was provided in two data sets:

    a) The first condition assessment data set (referred to hereafter as data set 1a) was from an earlier study conducted by Hydro One, i.e. Conductor End of Life Study dated August 2016. This set was used to perform exploratory data analyses as documented in Chapter 3.

    b) The second condition assessment data set (referred to hereafter as data set 1b) was provided at a later date and consists of additional OCS 4 data as well as additional samples from "Long Test Reports". This set was used to derive condition assessment based Weibull models as documented in Chapter 4.

2) Replacements and in-service fleet demographic data. The replacement data was used to derive the replacement-based Weibull model as documented in Chapter 4. The in-service fleet demographic data was used as the basis for calculating projections of circuit-kilometers that will reach conditions that require replacements in the future, as documented in Chapter 5.

The remainder of this chapter provides a more detailed description of the above mentioned data sets. Note that the following section on conductor assessment data focuses on data set 1b as this is the data used to derive the condition-based hazard functions.

Conductor Assessment Data

The conductor assessment data set (1b) comprises 443 records extracted from test reports dated from 2001 to 2016, with one assessment performed per conductor. Of the 443 records, 420 records applied to aluminum conductor steel reinforced (ACSR) samples, therefore the analysis focused on ACSR conductors. Other conductor types may perform differently.

The assessment data provided for each conductor included (1) demographic description such as age, size and stranding, and (2) condition assessment including extent of rust, severity of rust, remaining zinc, torsional ductility, and tensile strength. From this data, the project team explored how the conductor overall condition and its constituent assessment factors are affected by independent variables including age, conductor stranding, conductor size, and corrosion zone categorization.

Condition Assessment Methodology

The following describes the parameters considered by Hydro One when performing condition assessment on ACSR conductors. These condition parameters are derived through 3rd party laboratory testing on conductor samples typically five meters in length. These five condition parameters are:

1) Extent of Rust – Visual Inspection
2) Severity of Rust – Visual Inspection
3) Remaining Zinc – ASTM test
4) Torsional Ductility – ASTM test
5) Tensile Strength – ASTM test

Based on the test results, a 1 to 5 (best to worst) condition value was assigned for each test. Strand tests were translated to overall conductor state. Conductor overall condition is expressed as a weighted average, as shown in Table 2-1.

Table 2-1
Overall Conductor Condition: Weighted Average
(Source: *Hydro One Conductor Condition Assessment Program)*

Assessment (Test) Factor	Weight for Overall Condition
Extent of Rust	10%
Severity of Rust	10%
Remaining Zinc	10%
Torsional Ductility	30%
Tensile Strength	40%
Total	100%

Conductor Condition Assessment Data

The Hydro One Conductor Condition Assessment Program defines an overall condition score of 5 as equivalent to “end-of-life.” Hydro One provided condition assessment data collected between January 2001 and December 2016.

Investigators separated conductor assessment data by Overall Condition Score (OCS). Of the initial 404 conductor samples, 28 samples were assessed as OCS 5 from 21 different circuits and 61 samples were assessed as OCS 4 from an additional 29 different circuits. The remaining 315 samples were assessed as OCS 1 through 3.

Hydro One provided an additional set of 16 ACSR condition assessments based on “Long Test Reports” for 12 unique circuits. These were reports of more extensive laboratory investigations of this added set of field samples. All of these samples were considered as OCS 5 providing another 9 different circuits not assessed as OCS 5 in the previous data set.

Considering all the available assessment data, samples from a total of 30 unique circuits were deemed to have an OCS of 5. Figure 2-1 illustrates the circuits that are represented by all three subsets of the conductor assessment data, namely OCS 5, OCS 5 (long), and OCS 4. Note that three circuits are represented by both OCS 5 and OCS 5 (long). Nine circuits are represented by both OCS 5 and OCS 4, and five circuits are represented by both OCS 5 (long) and OCS 4. Among these intersections, three circuits (C27P, D2L) are represented by all three subsets.

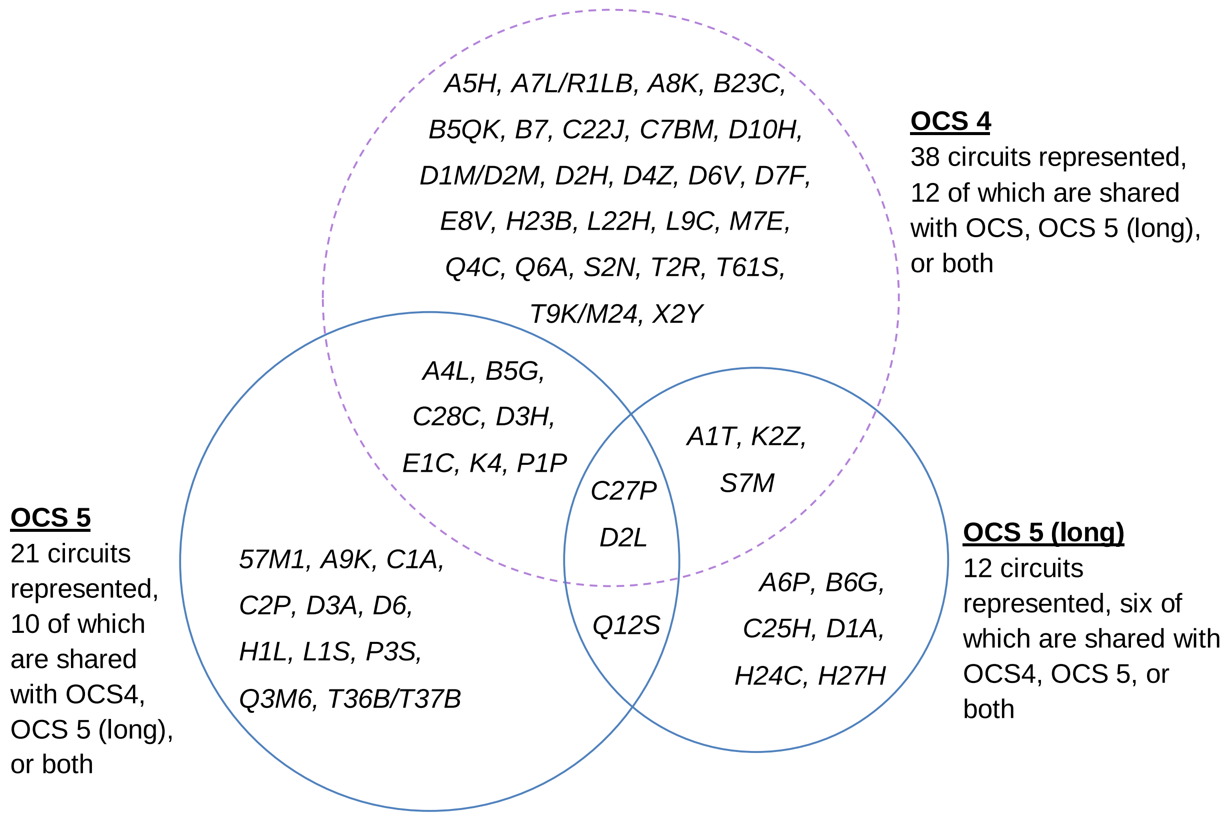

Figure 2-1
Venn Diagram Showing Circuits Associated with All Three Subsets of the Conductor Assessment Data, i.e. OCS 5, OCS 5 (long), and OCS 4, along with their Intersections

Replacements and In-Service Fleet Demographic Data

In addition to the assessment data, Hydro One provided historical replacement records. These replacement records span from January 1988 to January 2017 and the youngest age at replacement recorded was 41. A total of 126 replacement records were provided for 48 unique circuit designations and totaled 3,858 kilometers. Also provided was a list of in-service line sections and their ages representing 559 unique circuit designations. Figure 2-2 shows the cumulative installed conductor length by age, based on in-service ACSR fleet data as of October 2017.

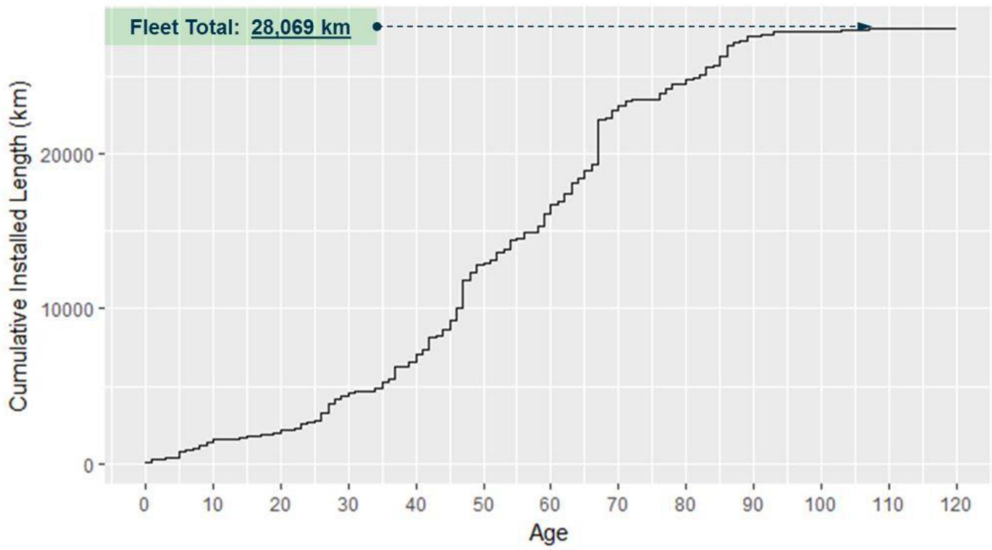

Figure 2-2
Cumulated Installed Length by Age (In-Service Fleet Data as of October 2017)

Figure 2-3 is a bar graph showing the installed length by age, again based on in-service fleet data as of October 2017.

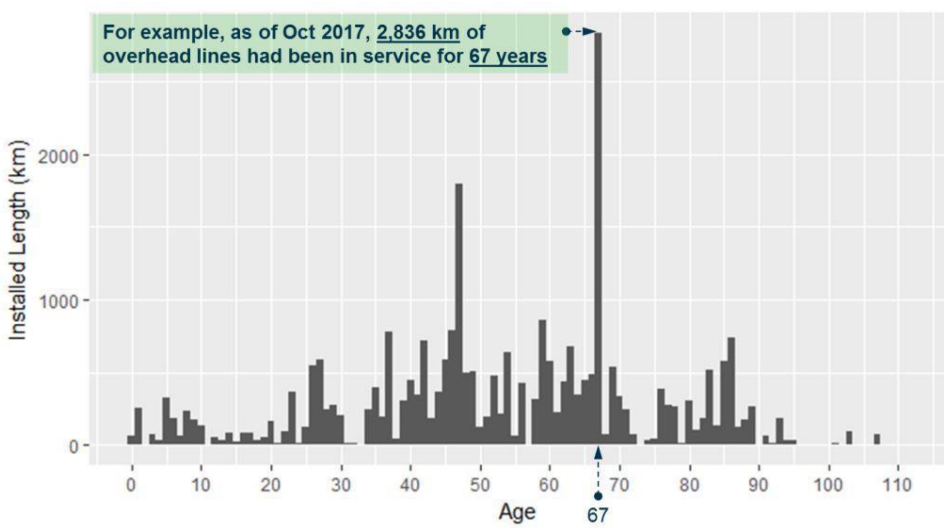

Figure 2-3
Installed Length by Age (In-Service Fleet Data as of October 2017)

Summary of Data Sources

Table 2-2 summarizes the collection periods, number of entries, and number of unique circuits associated with the OCS 5 data set and the replacement records data set.

Table 2-2
Summary of the Assessed OCS 5 Data Set and Replacement Records

Data Source	Collection Period	Number of Entries	Number of Unique Circuits within Data Source
Assessed OCS 5	1/2001 – 12/2016	44	30
Replacement Records	1/1988 – 1/2017	126	48

Figure 2-4 illustrates the circuits that are represented by the OCS 5 data set (including long samples) and replacement records data set. Note that 12 circuits are represented by both the OCS 5 data set and replacement records data set.

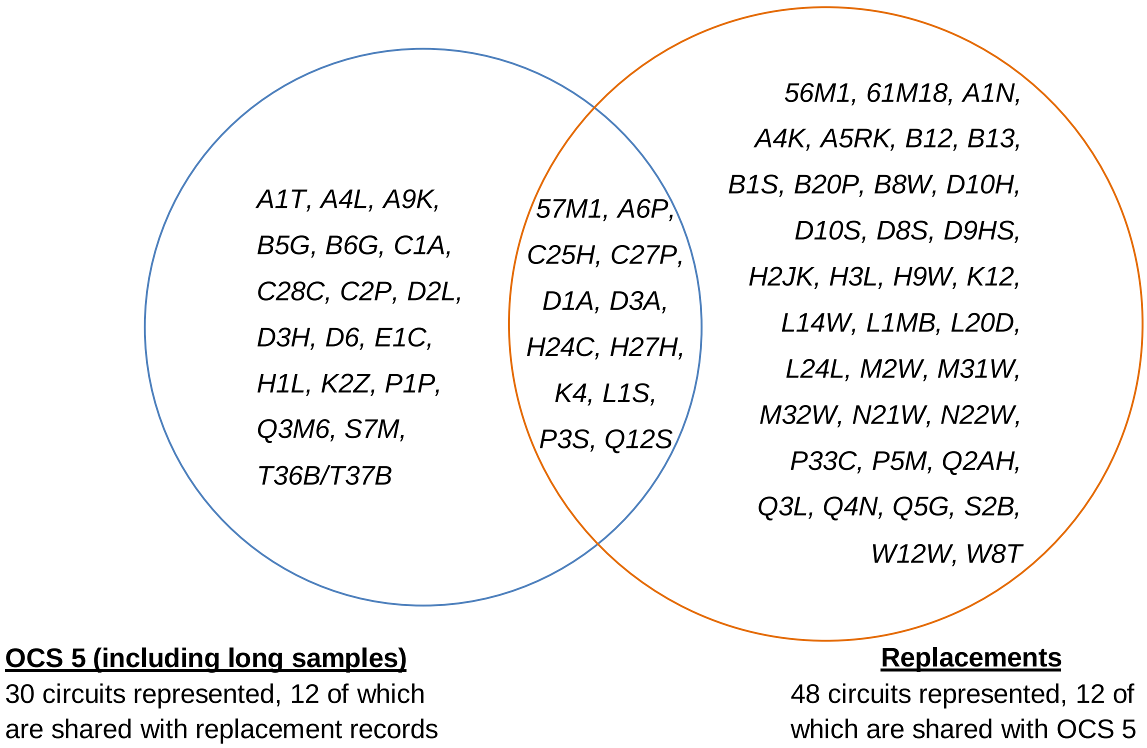

Figure 2-4
Venn Diagram Showing Circuits Associated with the OCS 5 Samples (including Long Samples) and Replacement Records Data Set, along with Their Intersections

3
EXPLORATORY ANALYSES ON CONDUCTOR CONDITION ASSESSMENT DATA

The first step of this effort was to closely examine the provided data (data set 1a) to better understand any useful relationships among the various parameters. Exploratory analyses were carried out on conductor condition assessment data, with a focus on ACSR conductor material types. In conducting these analyses, investigators sought to explore how the overall condition and its constituent conditions (assessment factors) are affected by the following independent variables:

- Age (years)
- Conductor stranding
- Conductor size
- Corrosion zone categorization

Correlation of Overall Condition with Age

The following three figures examine the relationships between overall condition and age; the third slide showing a histogram of conductor count by age between two overall condition groups (1-4 vs. 5). From these figures it may be observed that there is not a simple relationship between age and overall condition.

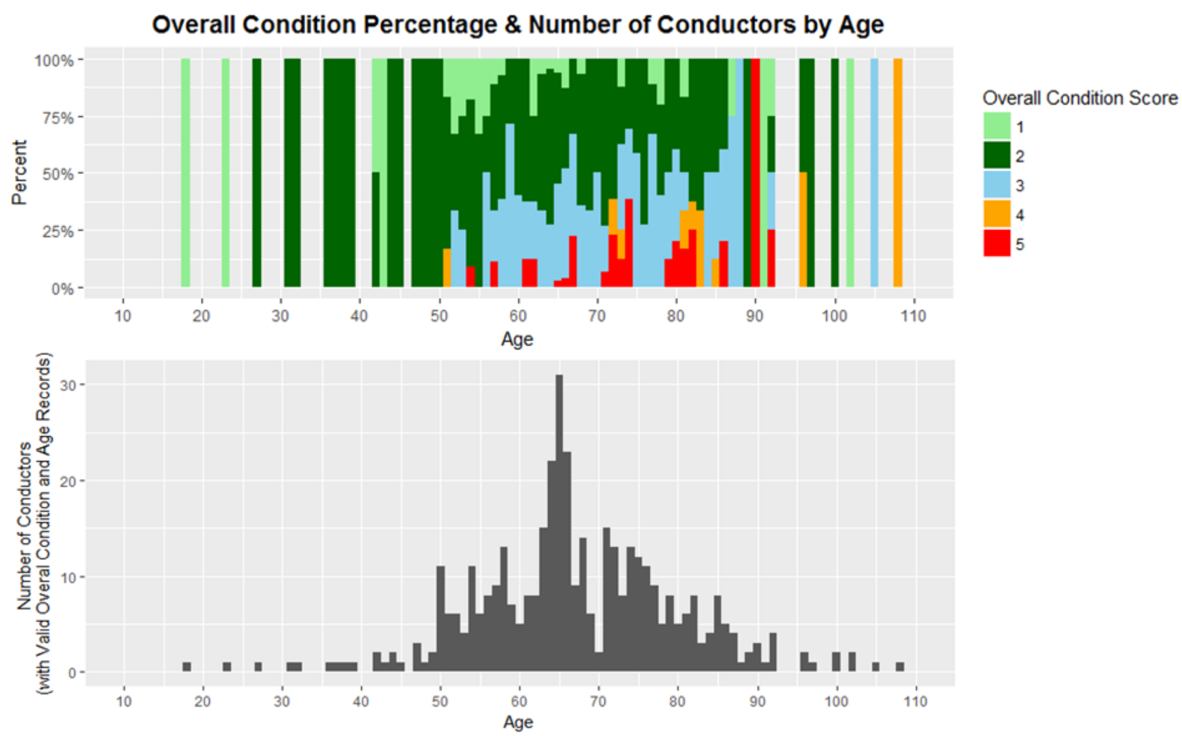

Figure 3-1
Overall Condition Percentage and Conductor Count by Age

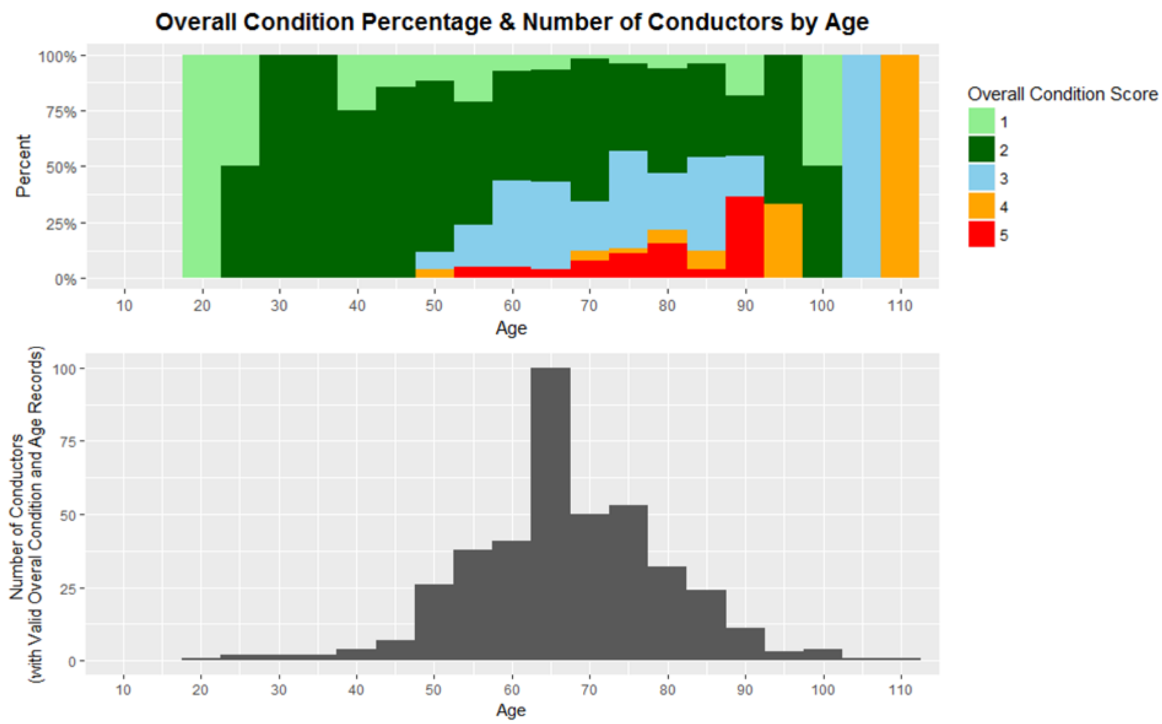

Figure 3-2
Overall Condition Percentage and Conductor Count by Age (5-Year Interval)

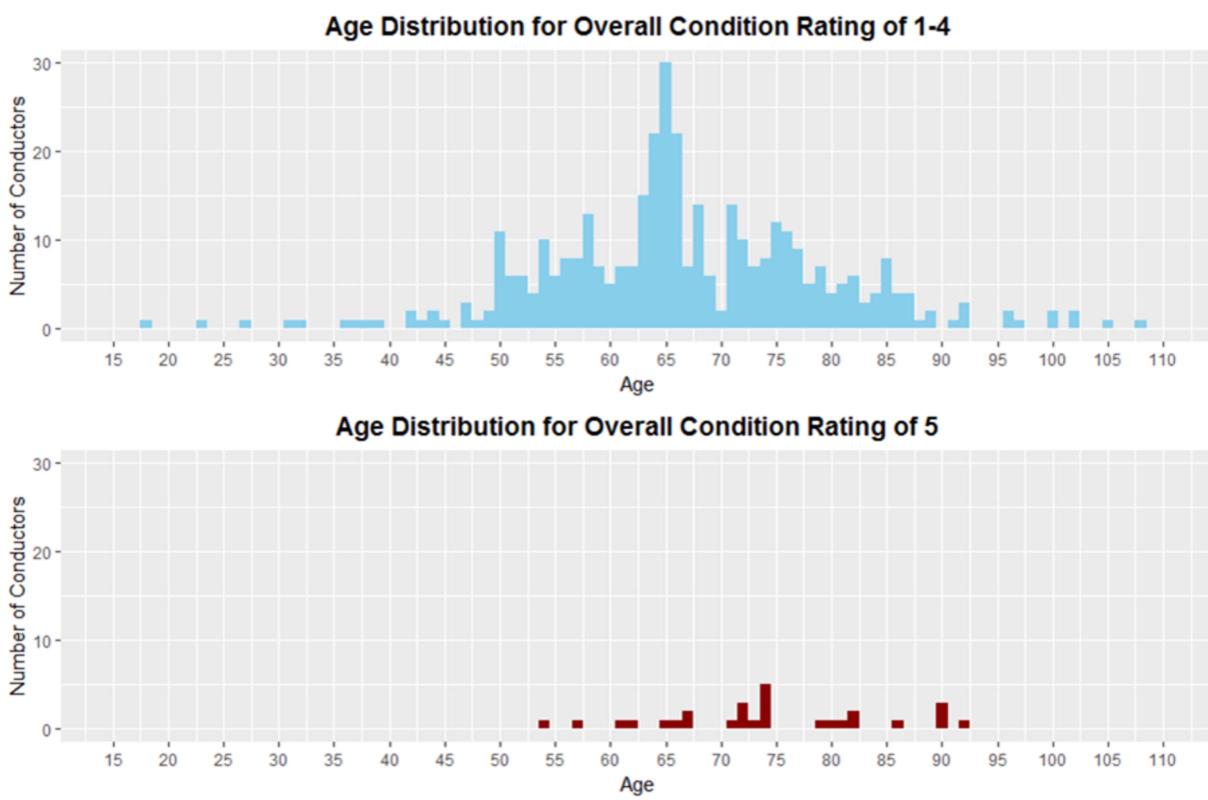

Figure 3-3
Age Distribution by Overall Condition

The analysis proceeded by looking at correlation of constituent conditions with age.

Constituent Conditions (Assessment Factors) by Age

Figure 3-4 through Figure 3-10 show how constituent conditions (assessment factors) correlate with age. The assessment factors include extent and severity of rust, remaining zinc, torsional ductility, and tensile strength.

No clear age-related pattern was observed with any of the constituent condition parameters.

Extent and Severity of Rust

Figure 3-4 shows the extent of rust by age, as determined by visual inspection. Figure 3-5 shows severity of rust by age.

From these two figures it may be observed that rust assessments do not appear to be reliable or useful assessment factors, possibly due to the subjective nature of visual inspection.

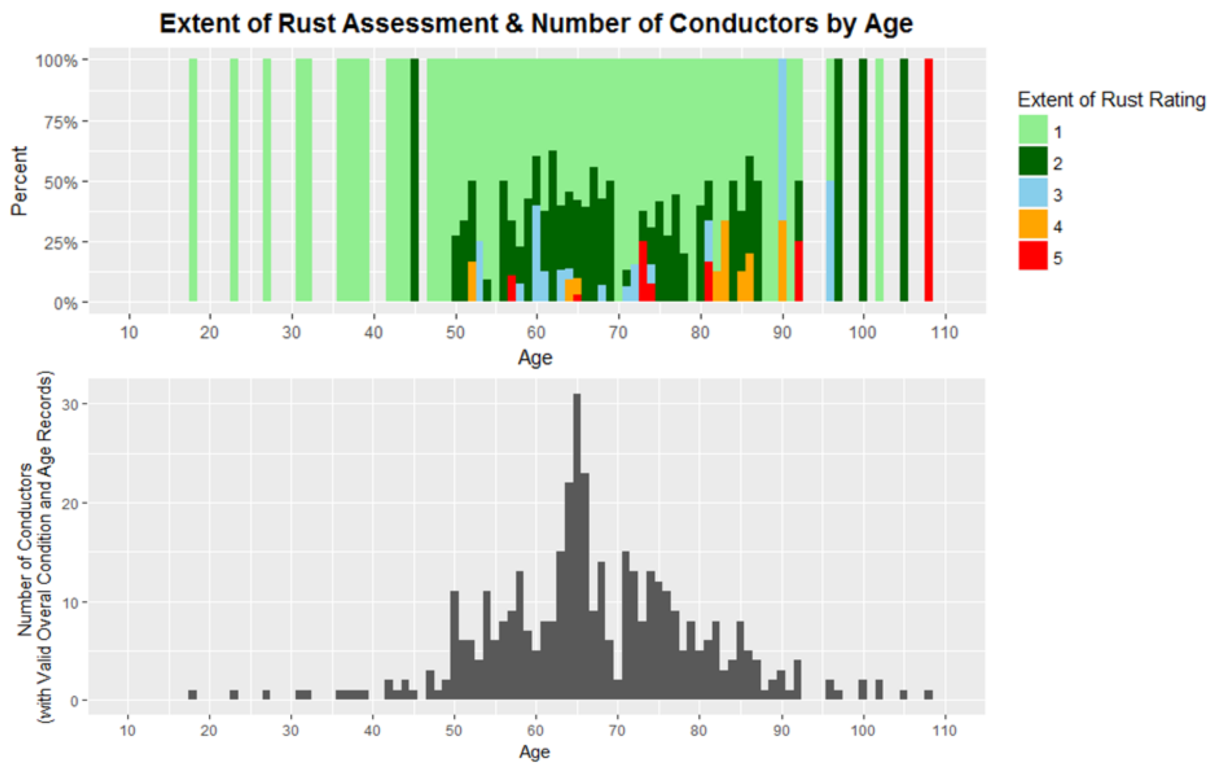

Figure 3-4
Extent of Rust by Age, as Determined by Visual Inspection

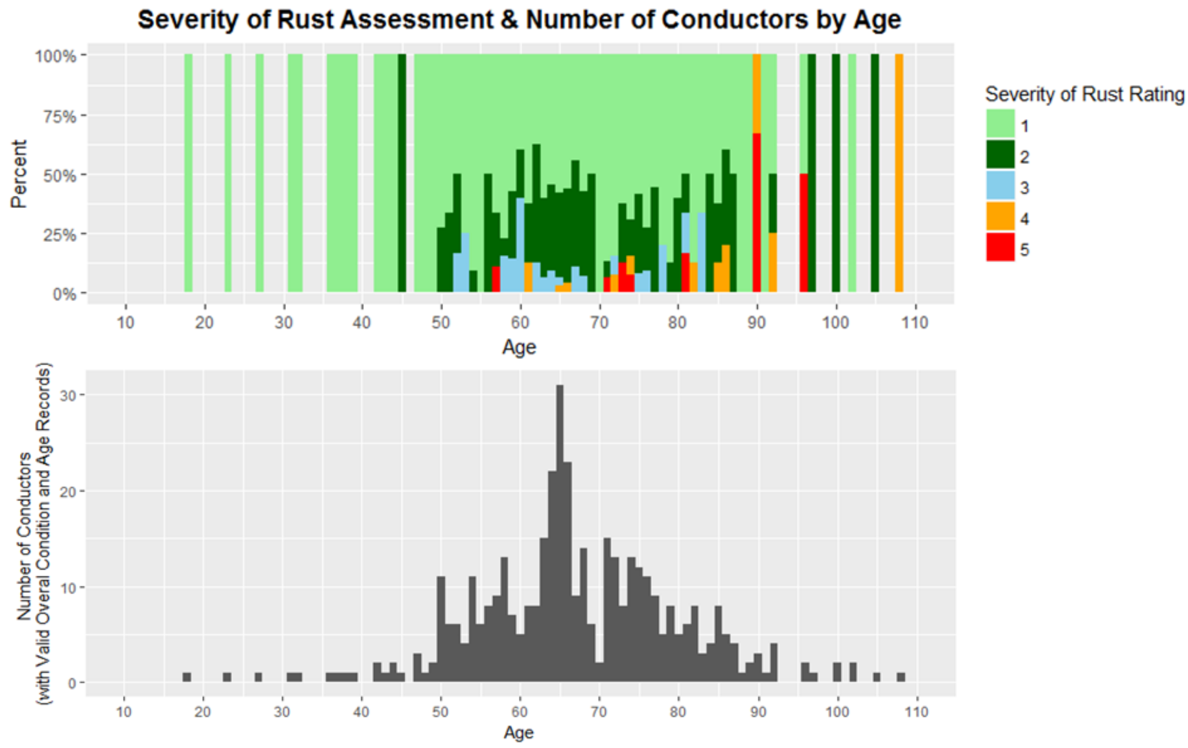

Figure 3-5
Severity of Rust by Age

Figure 3-6 investigates the correlation between severity and extent of rust. Dot size corresponds to the number of samples.

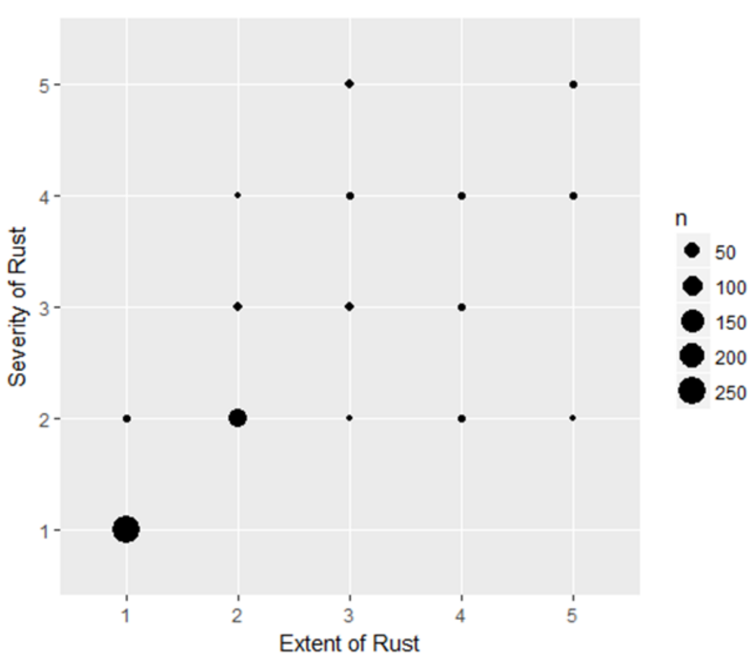

Figure 3-6
Severity vs Extent of Rust

Remaining Zinc

The deterioration of zinc galvanization may be a precursor indicating incipient corrosion of the steel core strands. Figure 3-7 shows remaining zinc by age and the number of conductor samples.

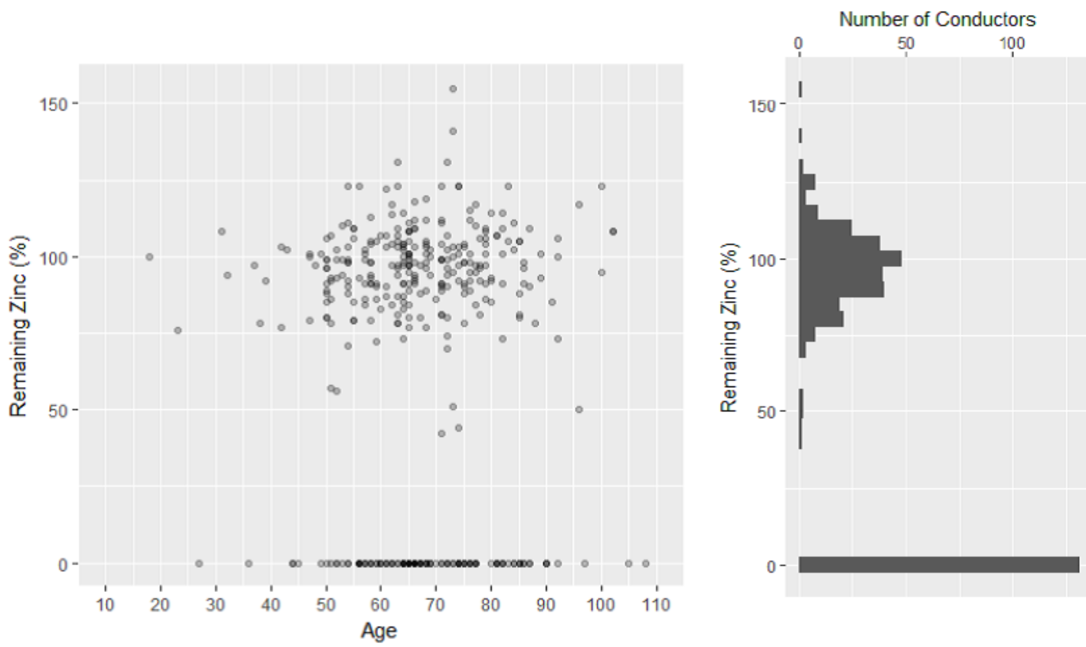

Figure 3-7
Remaining Zinc (%) by Age

Torsional Ductility by Age

Investigators measured torsional ductility of conductor samples per ASTM test specification, using a test rig that twists samples until failure. Results are shown in Figure 3-8.

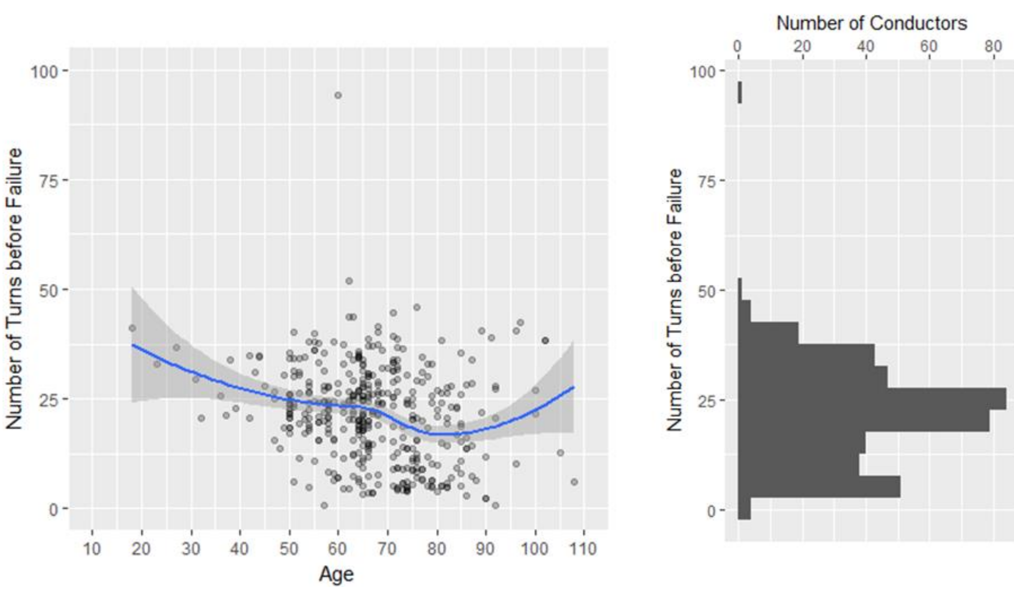

Figure 3-8
Torsional Ductility by Age

Tensile Strength by Age

Testing of tensile strength by age yielded the results shown in Figure 3-9.

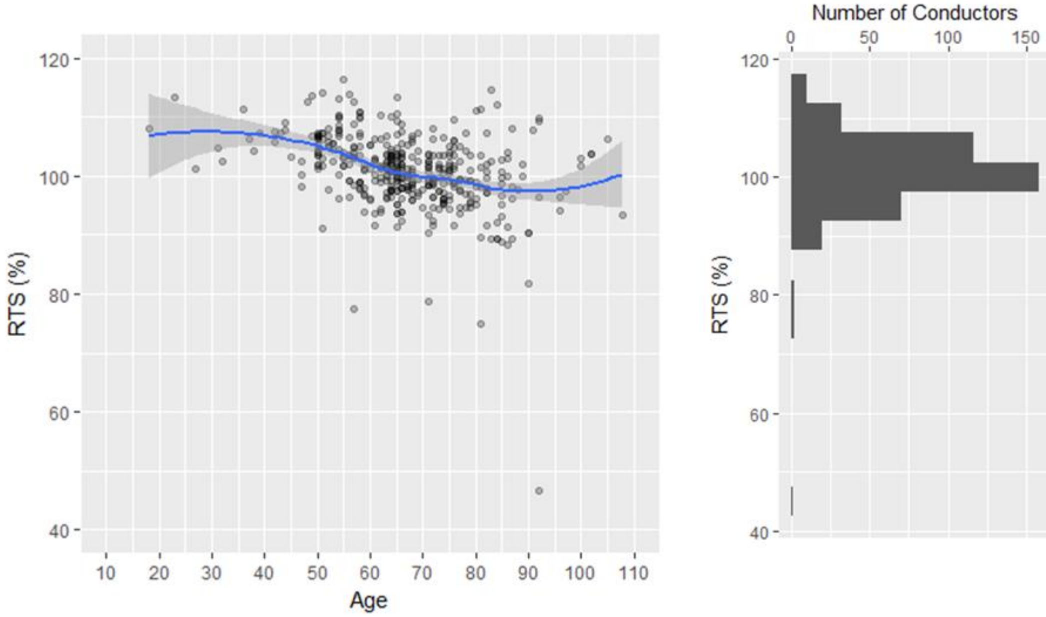

Figure 3-9
Tensile Strength by Age

Rust Assessments vs. Corrosion Zone

Investigators expected to see the best of rust ratings (e.g. 1, 2) skew towards corrosion zone C2 and C3, whereas the worst of the rust ratings (e.g. 5 or even 4) skew towards corrosion zone C5. However, such a pattern is not immediately apparent from the plots in Figure 3-10.

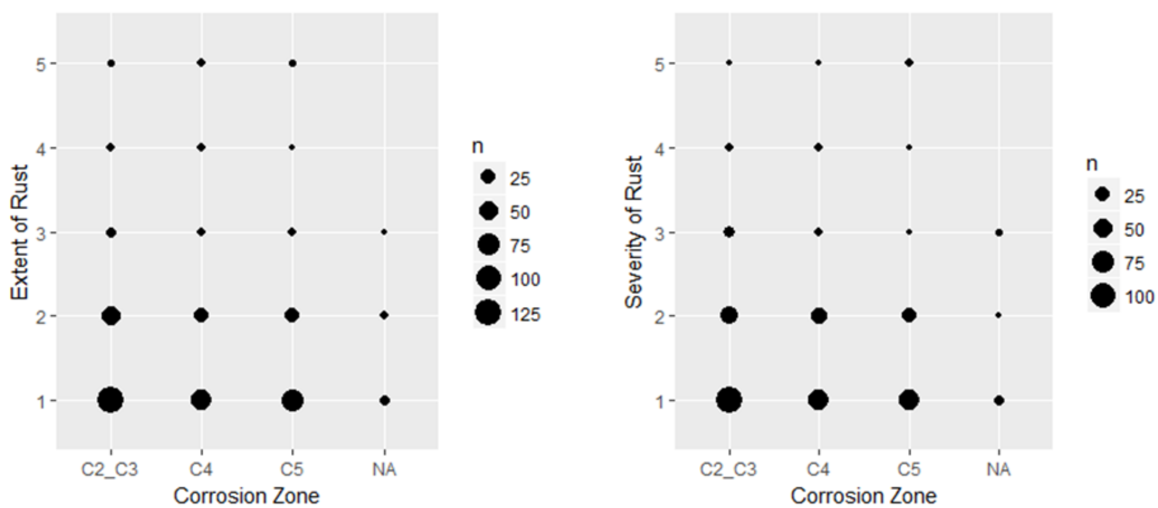

Figure 3-10
Rust Assessments vs. Corrosion Zone

Overall Condition by Conductor Stranding

Conductor stranding refers to the number of aluminum and steel strands comprising the outer layer and the inner core, respectively, of the ACSR conductor. A conductor with the designation 72/7, for example, has 72 outer aluminum strands and 7 inner steel strands. Figure 3-11 investigates any correlation of overall condition with conductor stranding. Figure 3-12 presents box plots illustrating age distributions at each level of stranding. (The boxes represent the middle half of the data; vertical lines represent the median.)

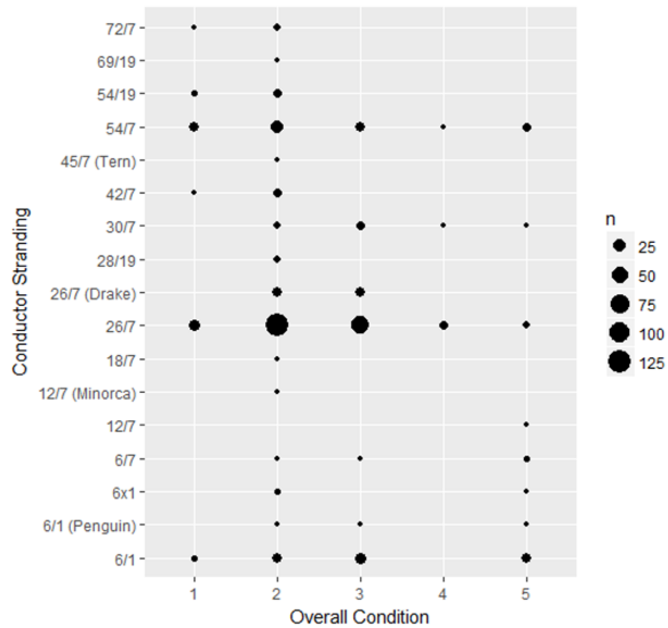

Figure 3-11
Correlation of Overall Condition by Conductor Stranding

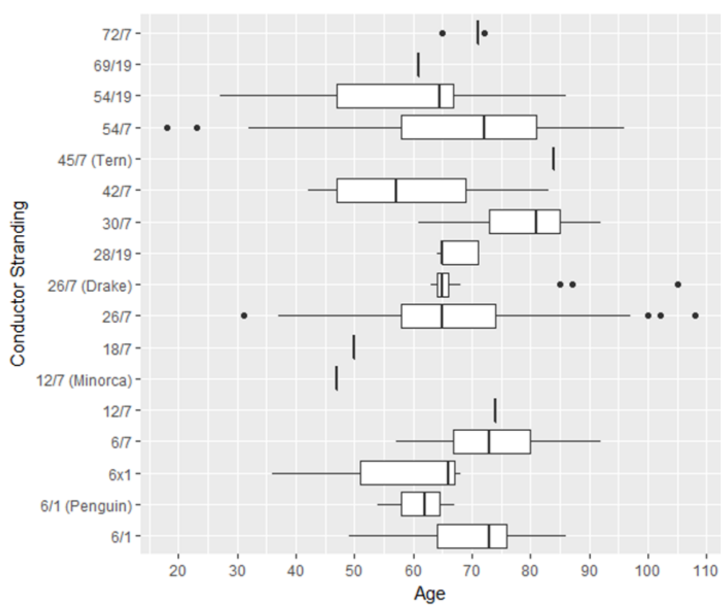

Figure 3-12
Conductor Stranding vs. Age

Overall Condition by Conductor Size

Investigators looked at the relationship between conductor size (based on cross-sectional area) and overall condition. Results are shown in Figure 3-13.

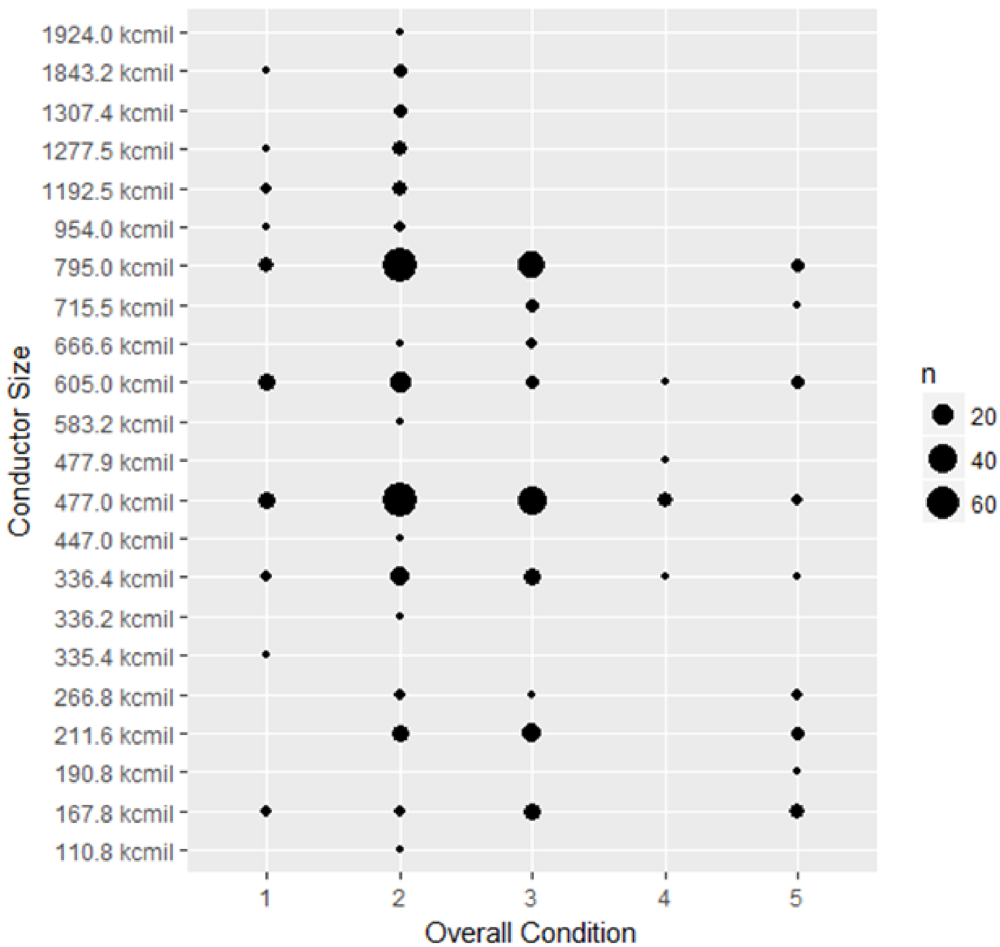

Figure 3-13
Overall Condition by Conductor Size

Conductor Size vs. Age

The project team next examined conductor size versus age. The box plots in Figure 3-14 illustrate age distributions at each conductor size level.

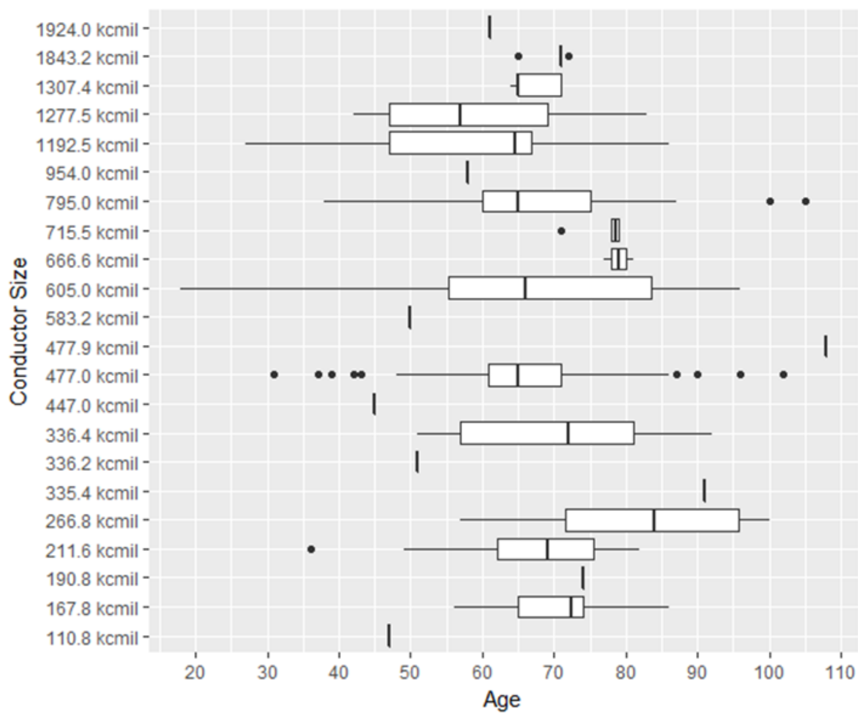

Figure 3-14
Conductor Size vs. Age

Conductor Stranding vs. Size

The exploratory analyses presented so far have focused on all of the ACSR conductor samples. This sample set contains conductors that vary in stranding and size, both of which can possibly be confounding factors that could mask any recognizable influence of age on overall or constituent conditions.

Figure 3-15 investigates any correlation between conductor stranding and size, which directs us to focus on the three smaller ACSR subsets (highlighted), namely 26/7 Drake, 26/7 Non-Drake, and 54/7. Each of these subsets is homogeneous in terms of stranding or size with a sample size larger than any remaining subsets.

Figures 3-16 through 3-42 show some analyses performed on each of these subsets with the objective of removing stranding or size as a possibly confounding factor.

Summary: Exploratory Analyses of the Three Subsets of Data

To review, the following three subsets of data were investigated:

- 26/7 Drake
- 26/7 Non-Drake
- 54/7

Even with these more homogeneous (though smaller) data subsets, Age does not appear to have a significant correlation with overall condition or any of the constituent conditions (assessment factors).

Next Steps

Investigators next narrowed in on even smaller data subsets where both stranding and size are homogeneous within each subset, without sacrificing too much on sample size

The investigation focused on the following stranding and size subsets of data:

- 26/7 and 795.0 kcmil
- 26/7 and 477.0 kcmil
- 54/7 and 605.0 kcmil

For each subset, the project team investigated:

- Remaining zinc by age and corrosion zone
- Torsional ductility by age
- Tensile strength by age

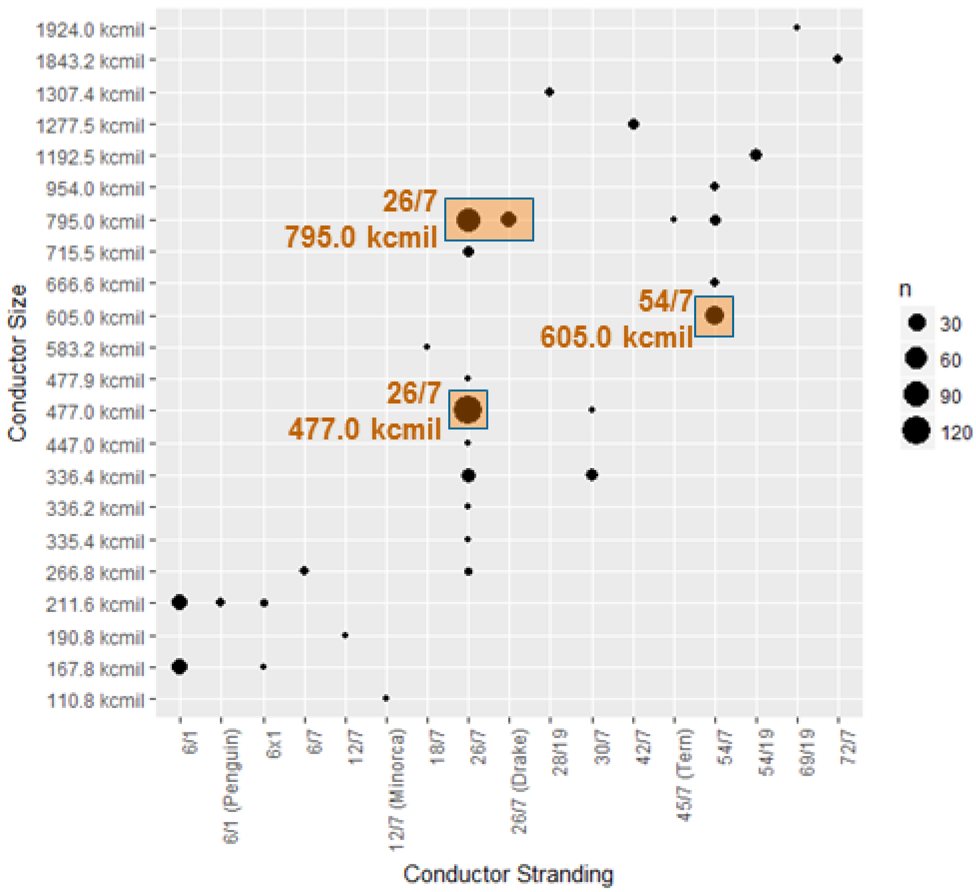

Figure 3-43
Conductor Stranding/Size Subsets Examined for Remaining Zinc, Torsional Ductility and Tensile Strength by Age

Remaining Zinc (%) by Age

Figure 3-44 shows remaining zinc by age, overlaying three groups of data. The plot does not reveal a clear age-related pattern for remaining zinc.

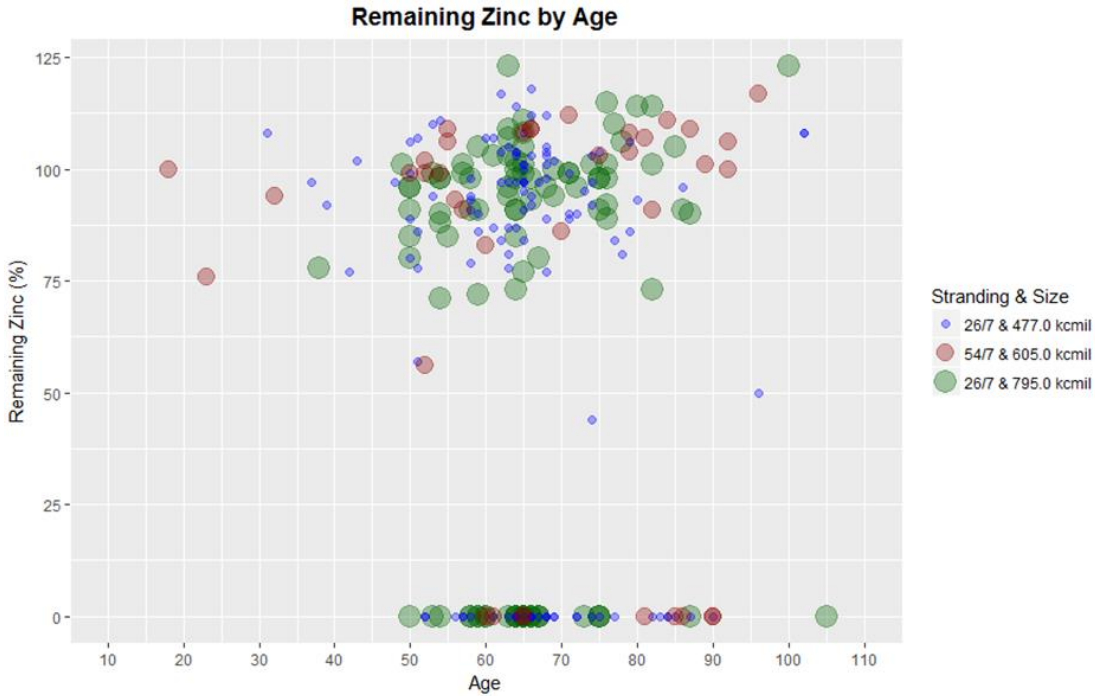

Figure 3-44
Remaining Zinc by Age for Three Stranding/Size Subsets

Figure 3-45 shows remaining zinc by age, with trend lines added, revealing even less of a clear pattern.

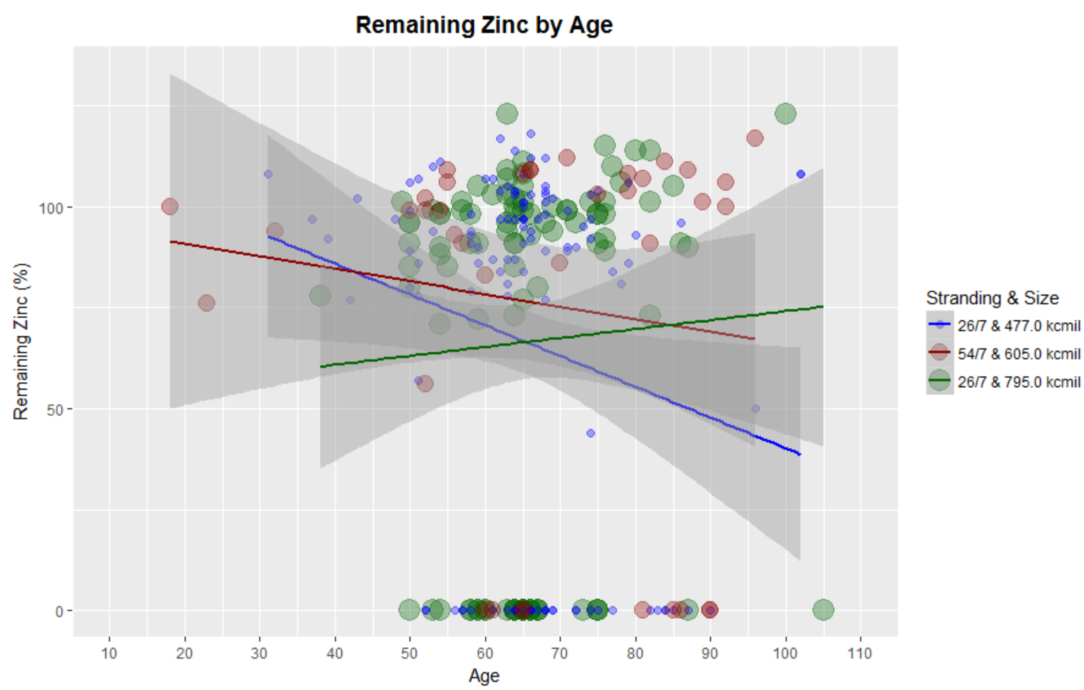

Figure 3-45
Remaining Zinc by Age: Trend Lines

Figure 3-46 shows remaining zinc by age, as well as age and density demographics. Again, no clear age-related pattern is evident.

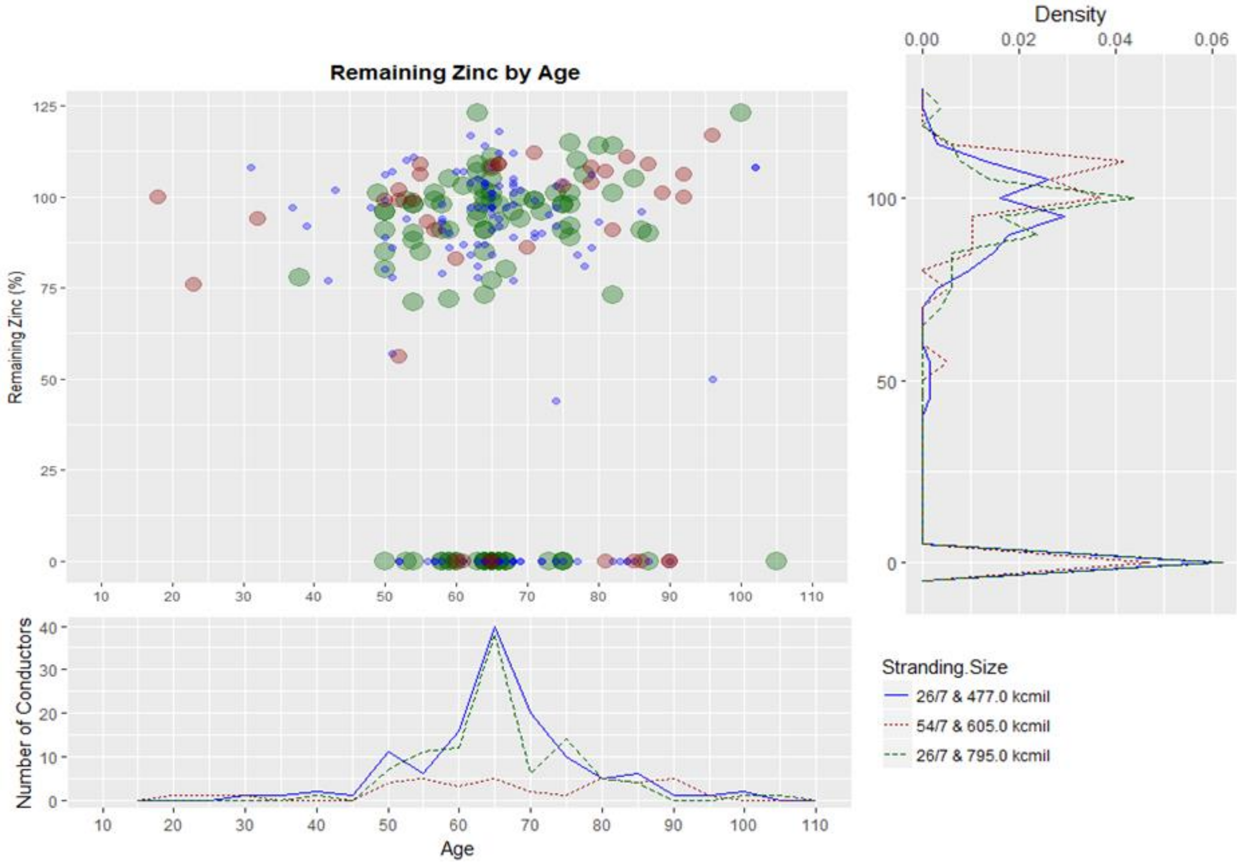

Figure 3-46
Remaining Zinc by Age with Demographics (Age, Density)

Remaining Zinc by Age and Corrosion Zone

The project team next investigated the relationship of remaining zinc and corrosion zone. The data did not show that corrosion zone was a significant factor in zinc loss.

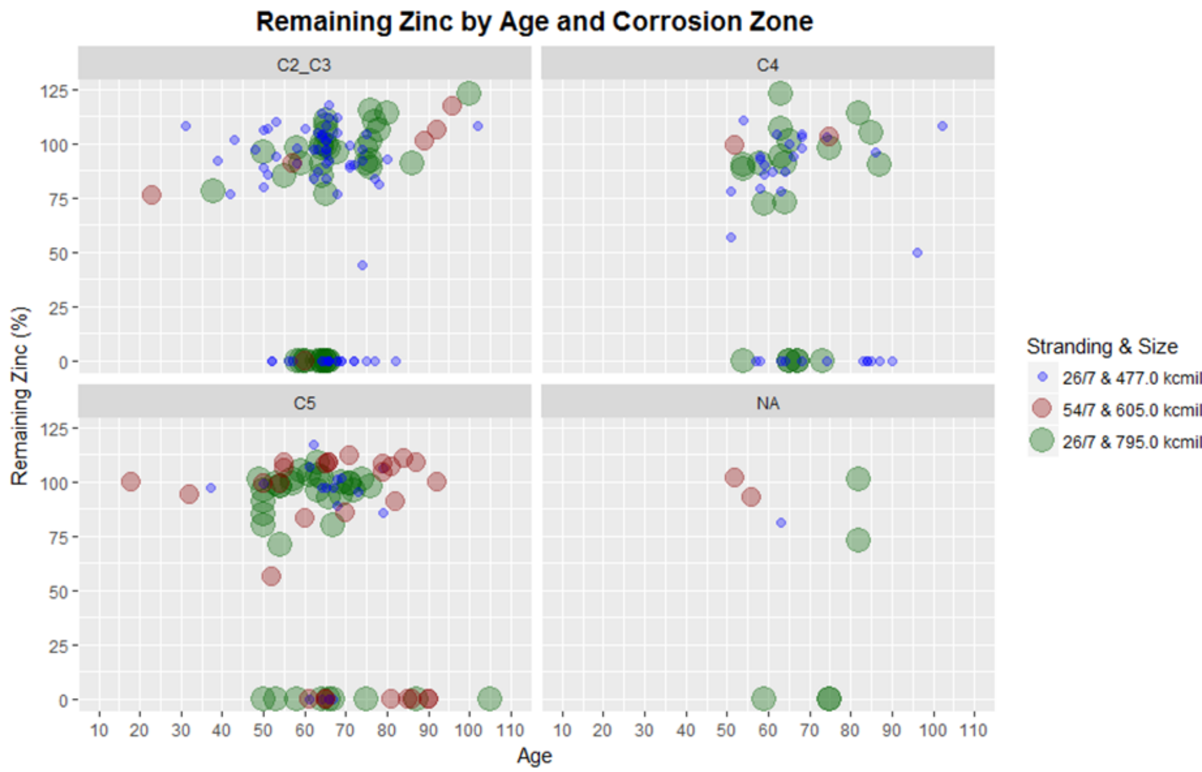

Figure 3-47
Remaining Zinc by Age and Corrosion Zone

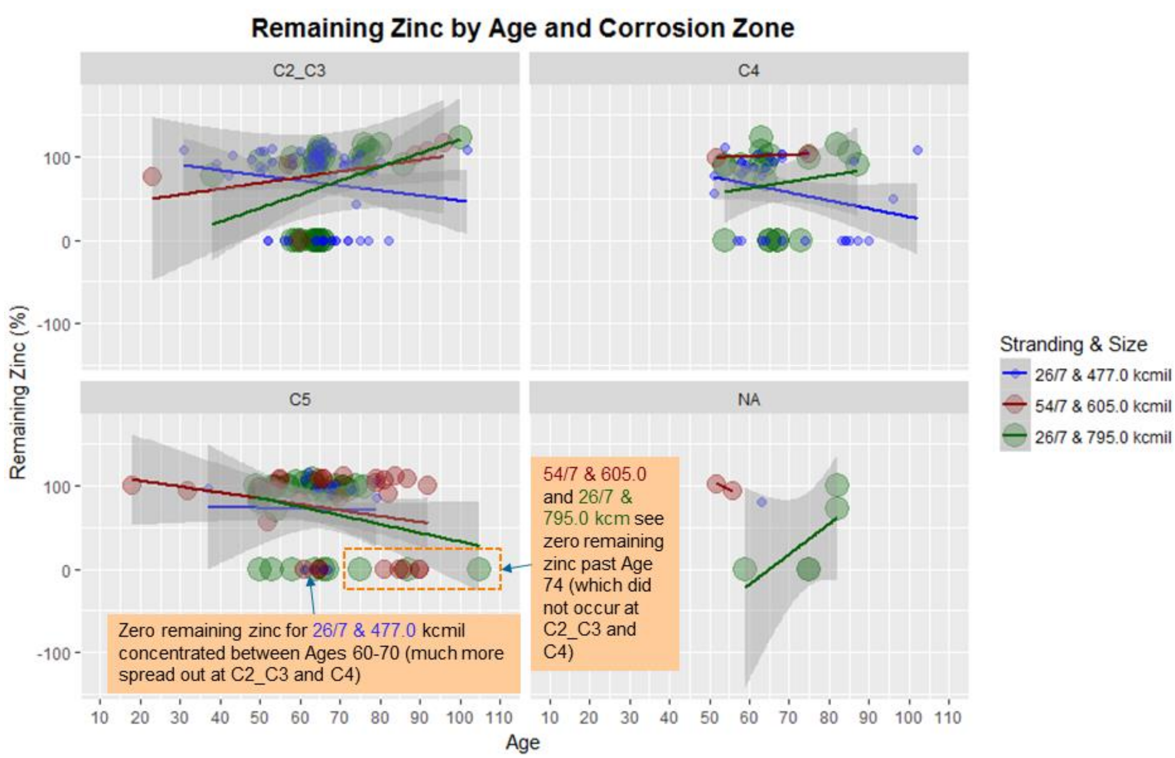

Figure 3-48
Remaining Zinc by Age and Corrosion Zone: Trend Lines

The following figures show no clear correlation between remaining zinc and age for all corrosion zone categories.

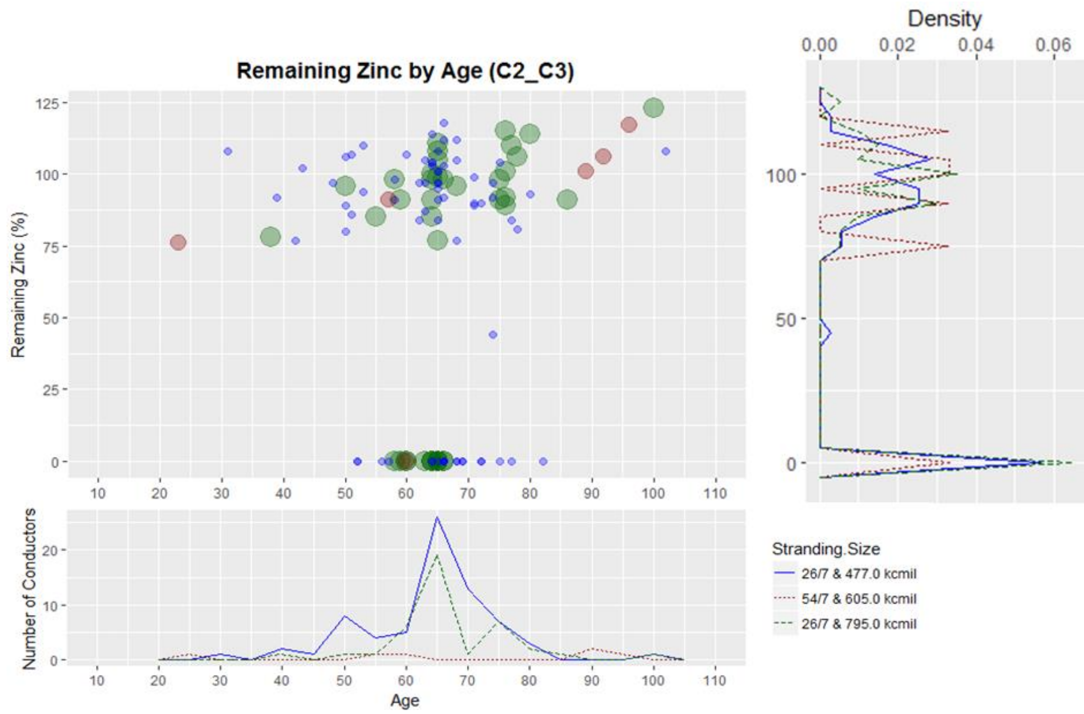

Figure 3-49
Remaining Zinc by Age: Corrosion Zones C2-C3

Figure 3-50
Remaining Zinc by Age: Corrosion Zone C4

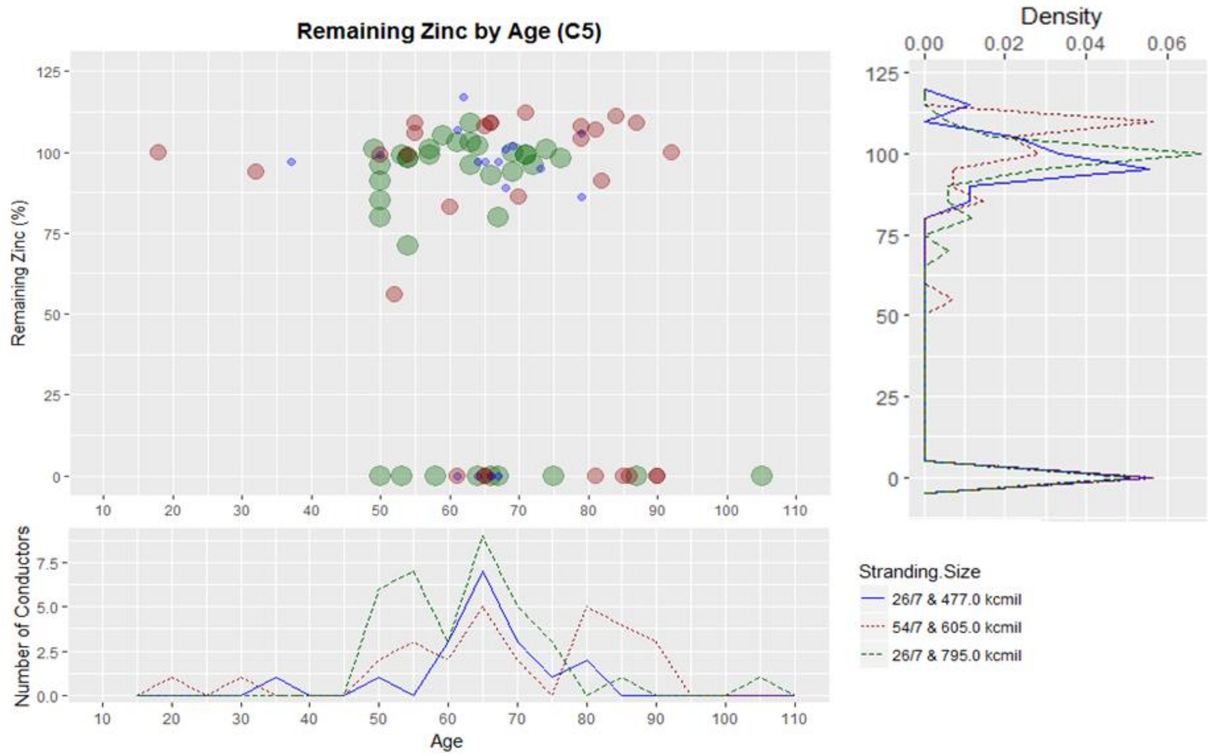

Figure 3-51
Remaining Zinc by Age: Corrosion Zone C5

Torsional Ductility by Age

Researchers next examined torsional ductility by age for the same three conductor subsets:

- 26/7 and 795.0 kcmil
- 26/7 and 477.0 kcmil
- 54/7 and 605.0 kcmil

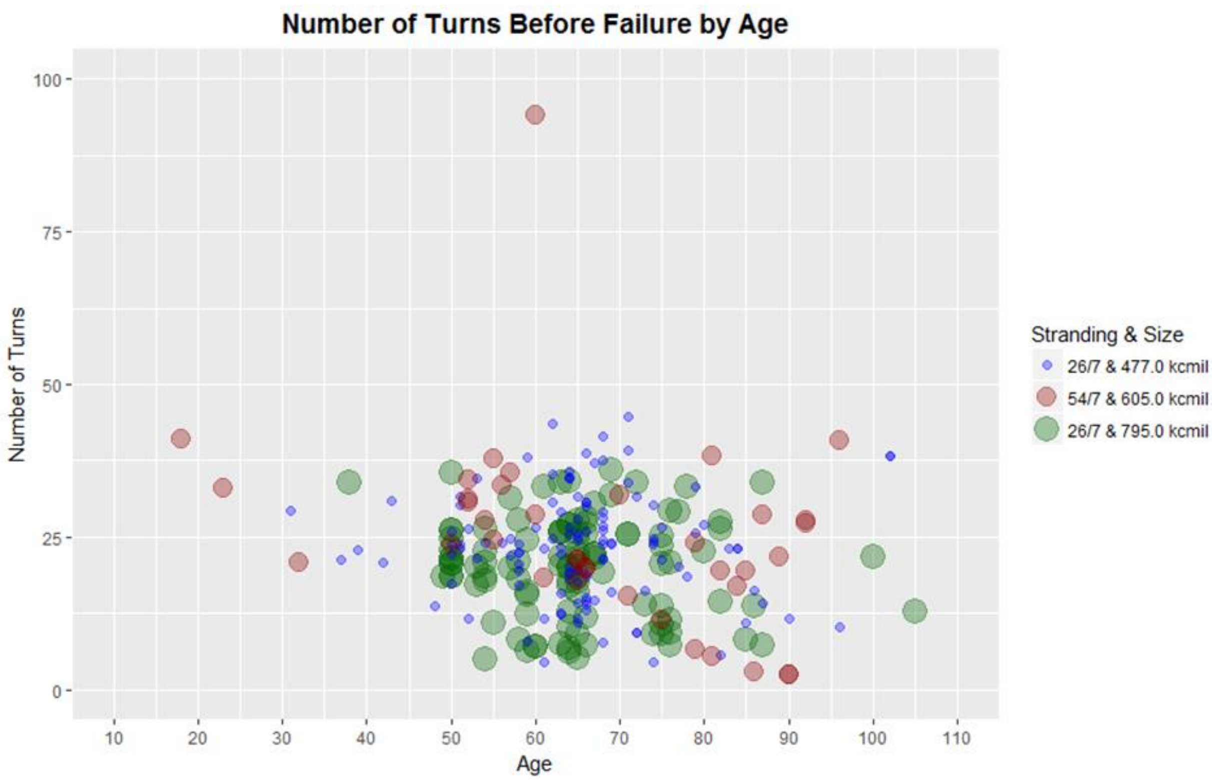

Figure 3-52
Torsional Ductility by Age

In terms of torsional ductility, 54/7 & 605.0 kcmil (i.e. more aluminum strands) seem to be more negatively affected by Age.

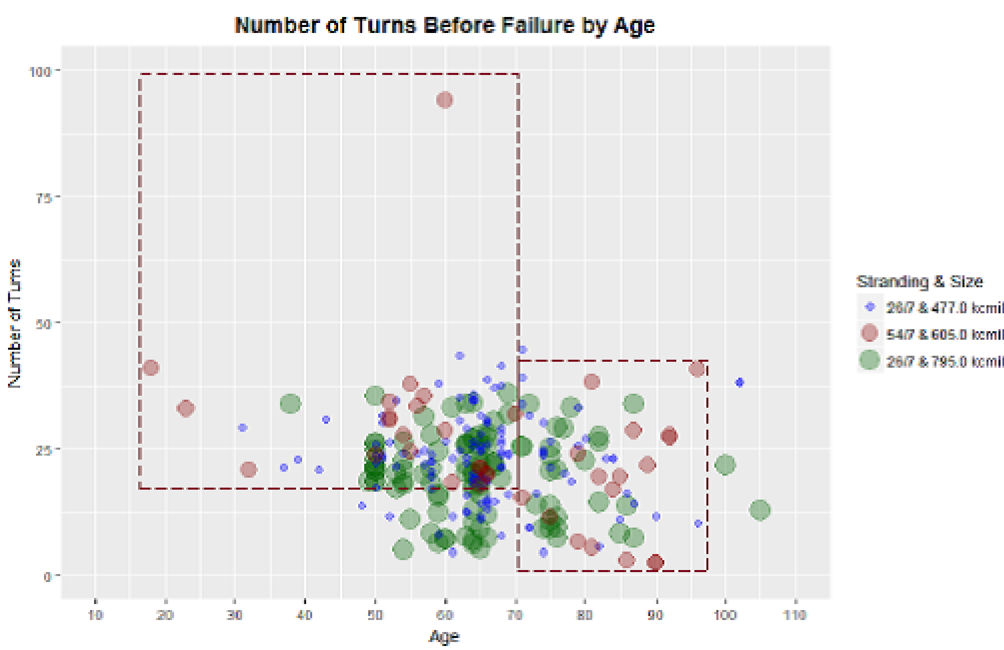

Figure 3-53
Torsional Ductility: Number of Turns Before Failure by Age

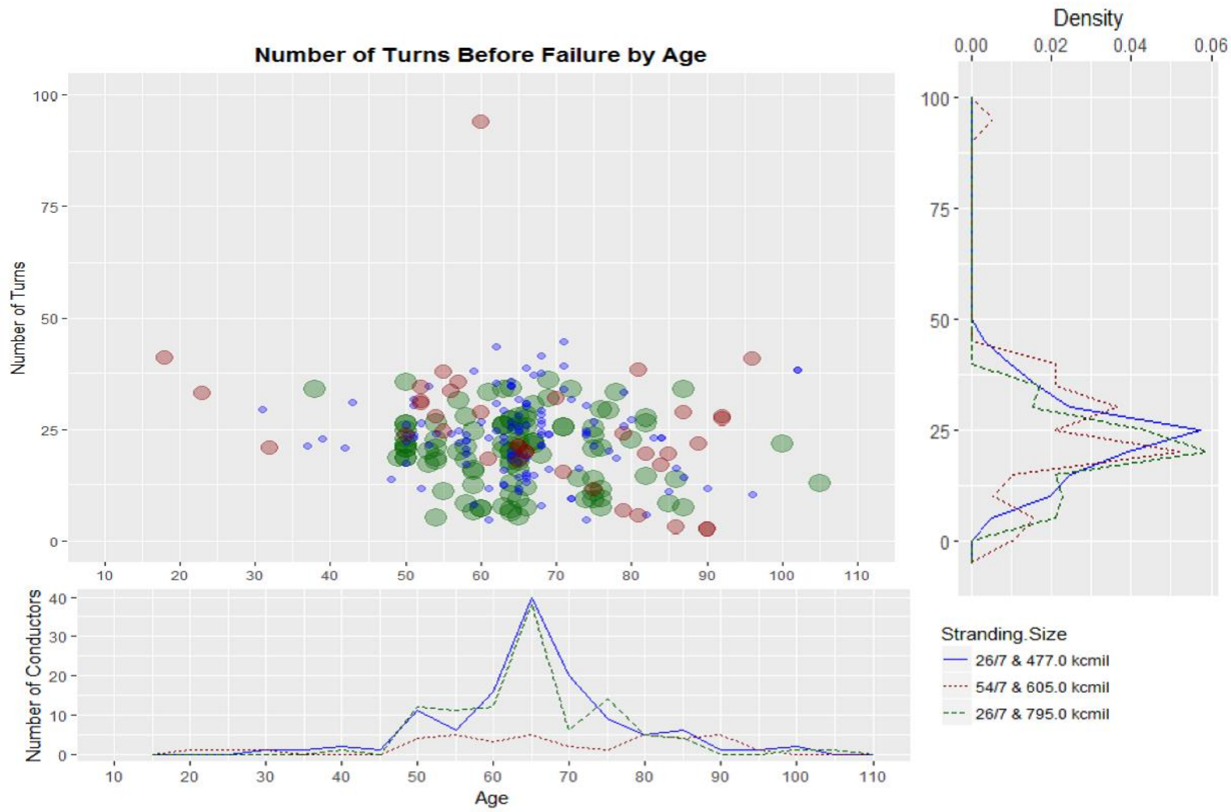

Figure 3-54
Torsional Ductility: Demographics

Tensile Strength by Age

The project team next investigated tensile strength by age for the same three conductor subsets:

- 26/7 and 795.0 kcmil
- 26/7 and 477.0 kcmil
- 54/7 and 605.0 kcmil

As shown in the following figures, there seems to be a general trend of decreased tensile strength with increased age. The conductor subset with the largest size (26/7 &795.0 kcmil) seems to be less affected by age than the two conductor subsets corresponding to 26/7 & 477.0 kcmil and 54/7 & 605.0 kcmil.

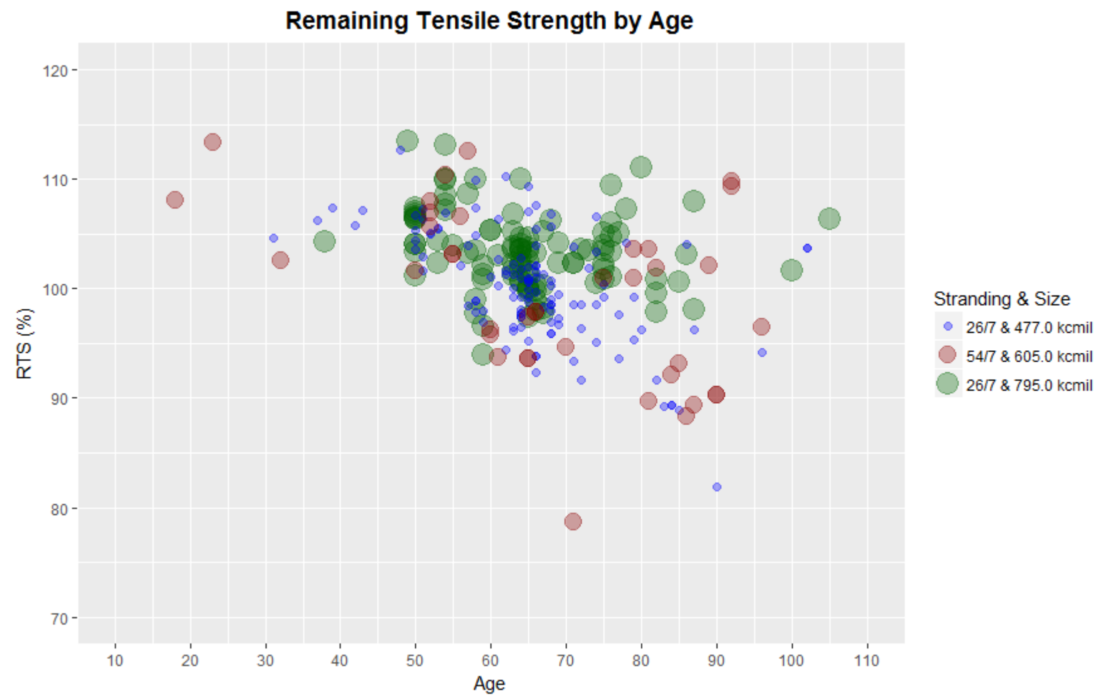

Figure 3-55
Tensile Strength by Age

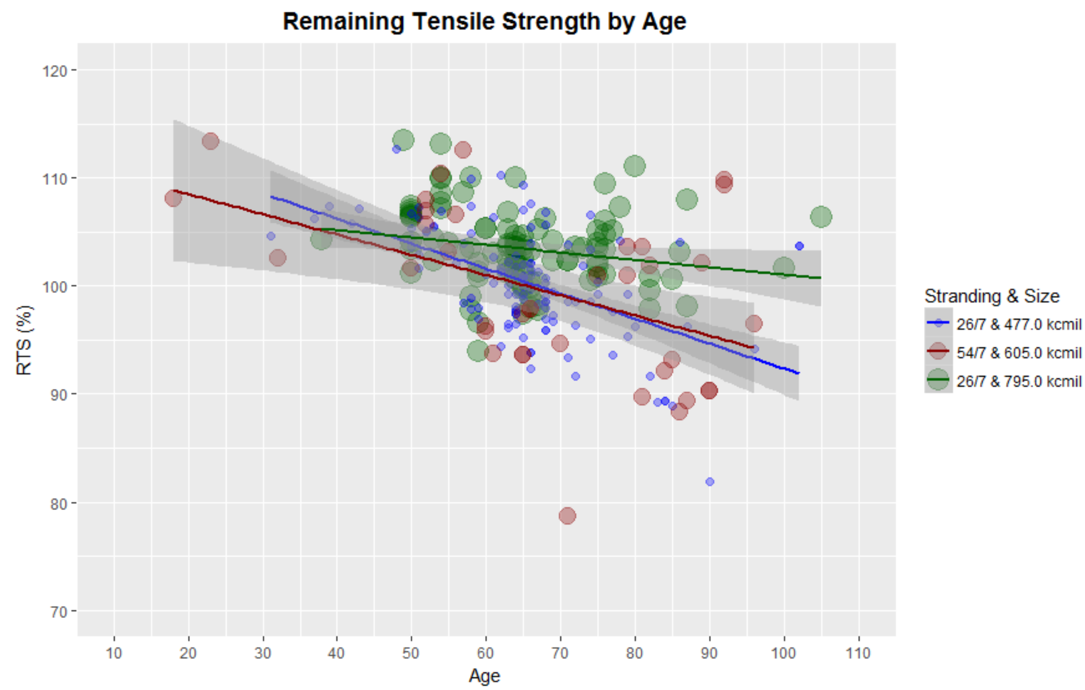

Figure 3-56
Tensile Strength by Age: Trend Lines

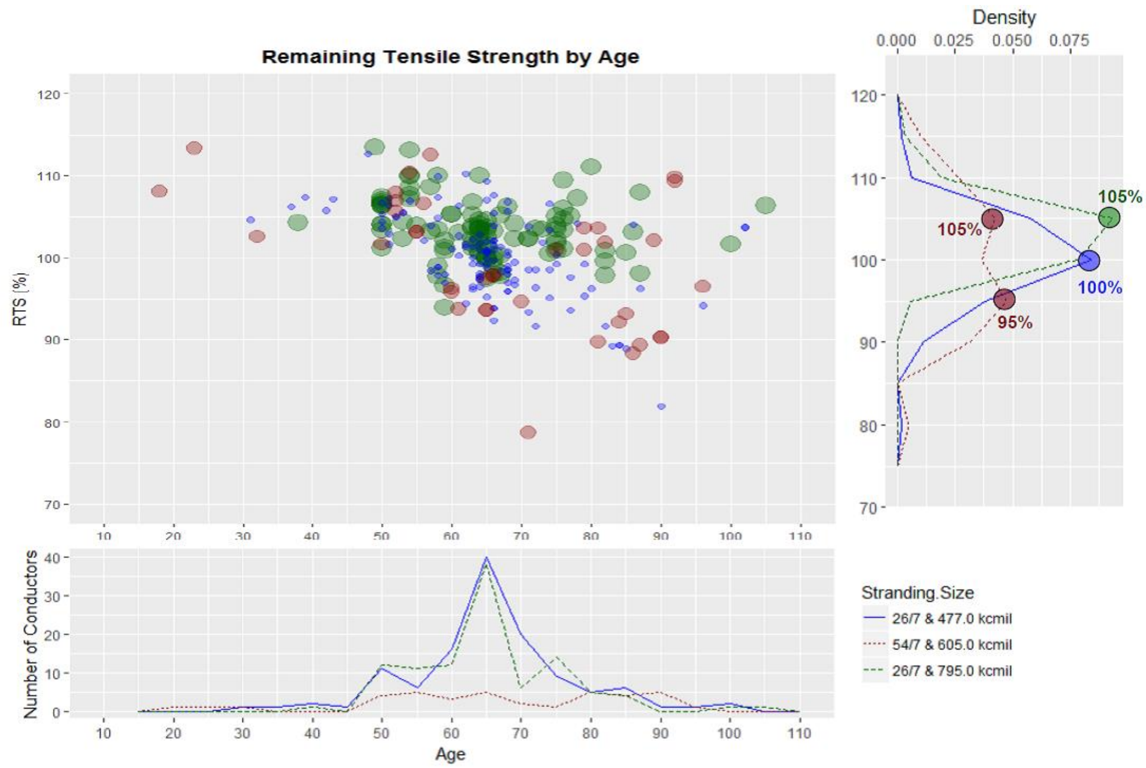

Figure 3-57
Tensile Strength by Age: Demographics

Overall Condition by Age

Researchers next examined the relationship between overall condition and age for the same three conductor subsets. The following figures show no clear age-related patterns.

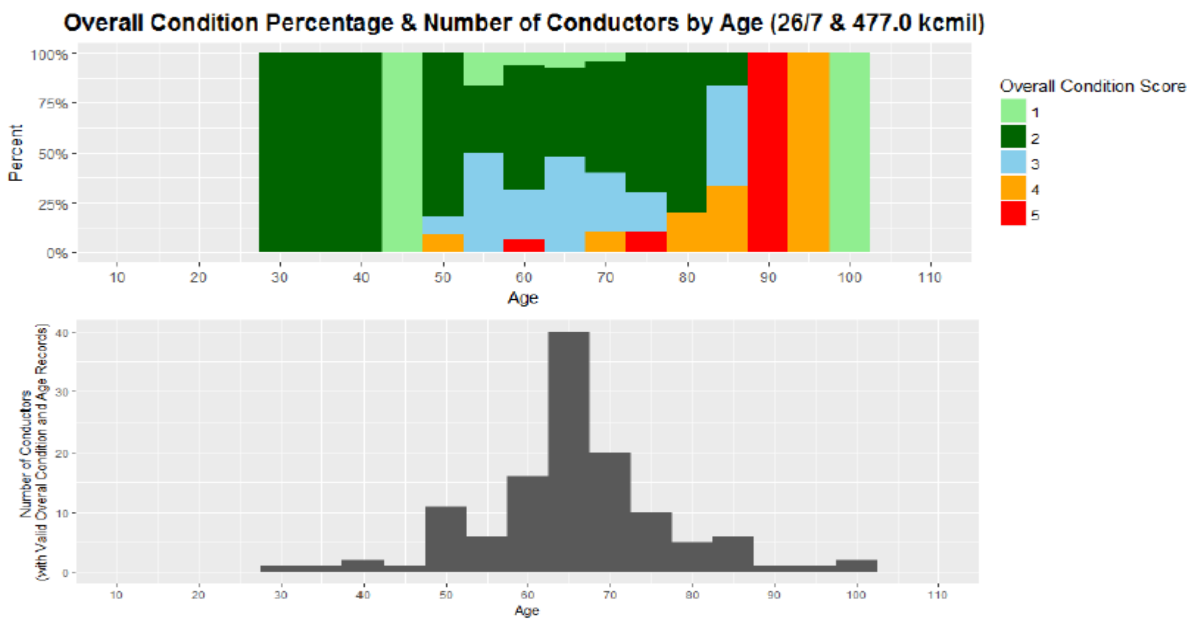

Figure 3-58
Overall Condition by Age (26/7 & 477.0 kcmil)

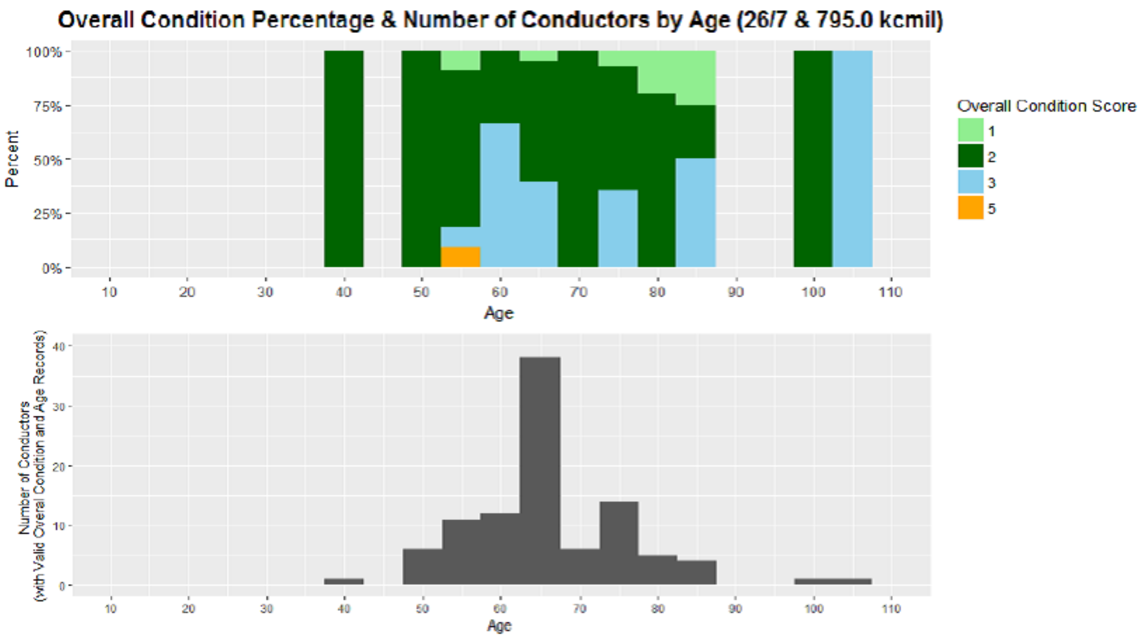

Figure 3-59
Overall Condition by Age (26/7 & 795.0 kcmil)

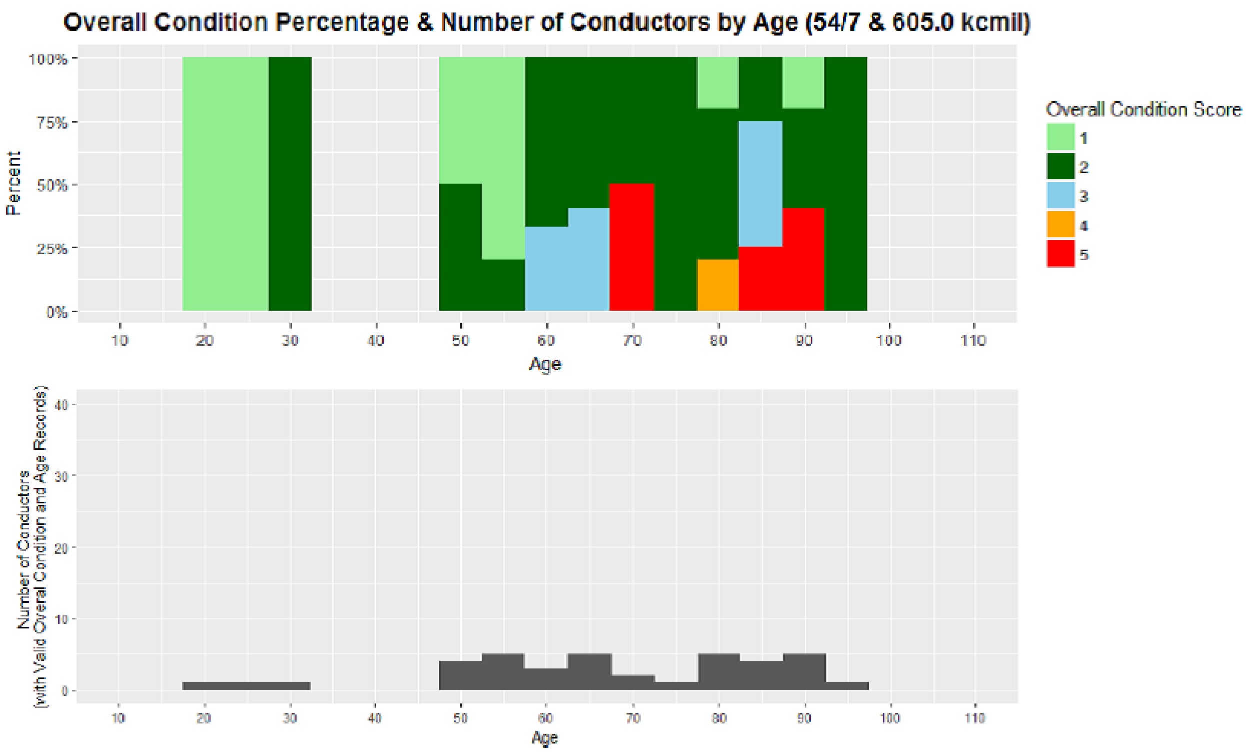

Figure 3-60
Overall Condition by Age (54/7 & 605.0 kcmil)

The investigations focusing on smaller and more homogeneous data sets revealed no clear correlations between overall condition and age, similar to the findings for the larger data set.

Among assessment factors, only torsional ductility and tensile strength have shown some recognizable age-related patterns. Consequently, researchers moved to examined the suitability of considering torsional ductility or tensile strengths as dependent variables (in lieu of overall condition) as a function of age. It is noted that, according to the Hydro One conductor assessment methodology, the end-of-life threshold for torsional ductility is number of turns ≤ 5 and the end-of-life threshold for tensile strength is remaining tensile strength (RTS) ≤ 85%.

Investigation of Failed Sample Data Only

Investigators next examined the conductor assessment data, by looking at:

- Percent of Overall Condition Rating of 5 by Age
- Percent of "Torsional Ductility Failure" (#Turns ≤ 5) by Age
- Percent of "Tensile Strength Failure" (RTS% ≤ 85%) by Age

Data sets examined included three ACSR selected sets as listed below:

- All ACSR
- 26/7 & 795.0 kcmil
- 26/7 & 477.0 kcmil
- 54/7 & 605.0 kcmil

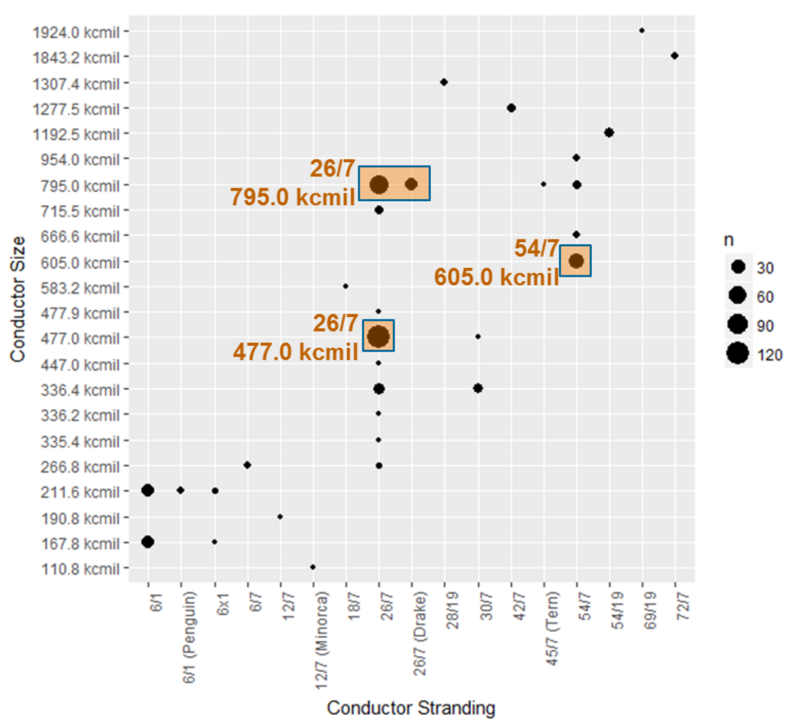

Figure 3-61

Tensile Strength Failure (RTS% ≤ 85%) by Age (26/7 & 795.0 kcmil)

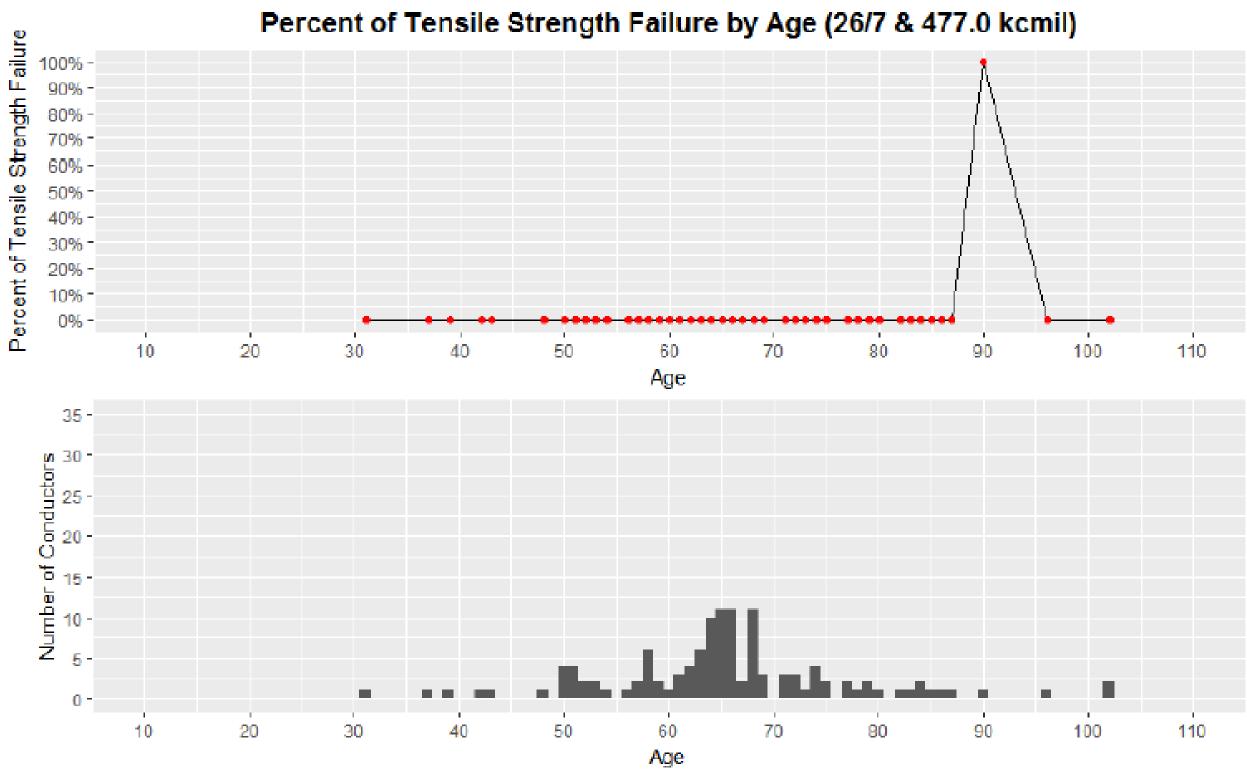

Figure 3-80
Tensile Strength Failure (RTS% ≤ 85%) by Age (26/7 & 477.0 kcmil)

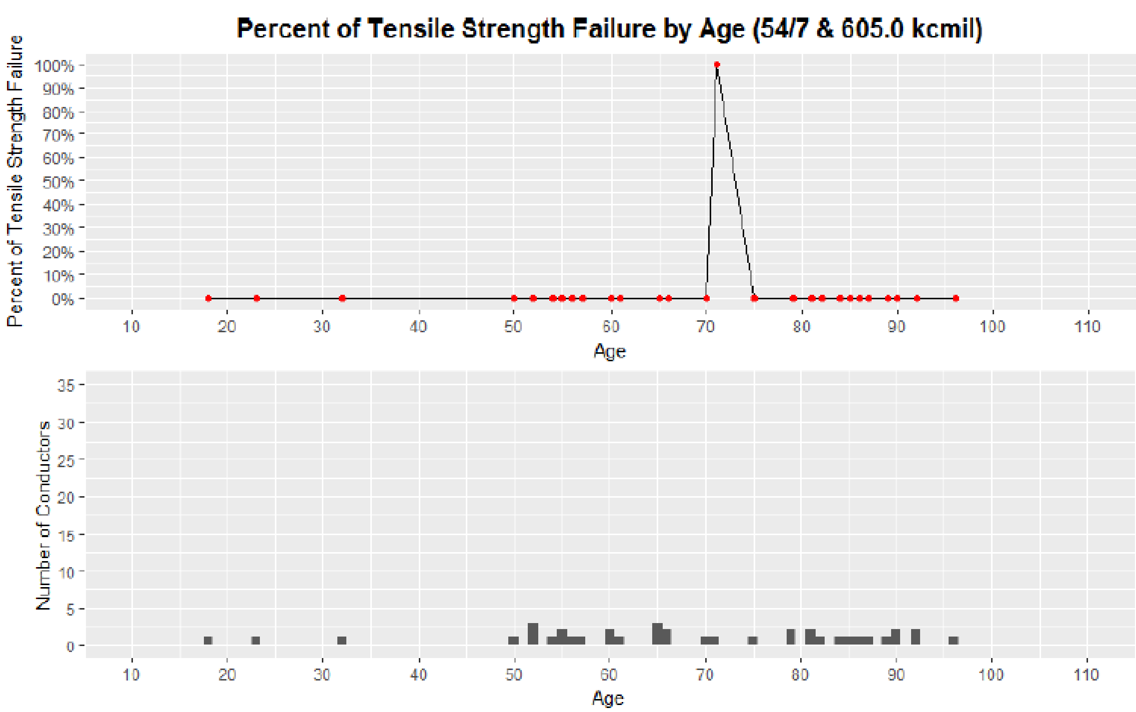

Figure 3-81
Tensile Strength Failure (RTS% ≤ 85%) by Age (54/7 & 605.0 kcmil)

The preceding figures show that when treating torsional ductility and tensile strength as dependent variables, end-of-life occurrences are too sparse to yield any meaningful age-related models for hazard functions. The same issues occurred when using smaller data sets regardless of dependent variables. This pointed researchers back to using the overall condition score as the dependent variable and treating all ACSR data as a single data set for modeling purposes. The practical result is that no age dependent progressive degradation model (i.e. one that would model the progression from condition 1 to 2, 2 to 3, etc.) could be developed.

Exploratory Analyses Conclusions

EPRI analyses confirmed the finding from the Hydro One "Conductor End of Life Study" that corrosion zone factor has no demonstrated effect on assessed degradation. Investigators set aside corrosion zone factor and treated all ACSR data as a single data set.

Investigators also found no meaningful relationships among the overall condition and its constituent conditions (assessment factors):

- Extent of Rust
- Severity of Rust
- Remaining Zinc
- Torsional Ductility
- Tensile Strength

and conductor stranding or conductor size.

However, a relationship between EOL condition and age was indicated. The following figure shows the percent of conductor samples with Overall Condition Score of 5 plotted by age, with "Long Test Reports" data included as additional EOL samples.

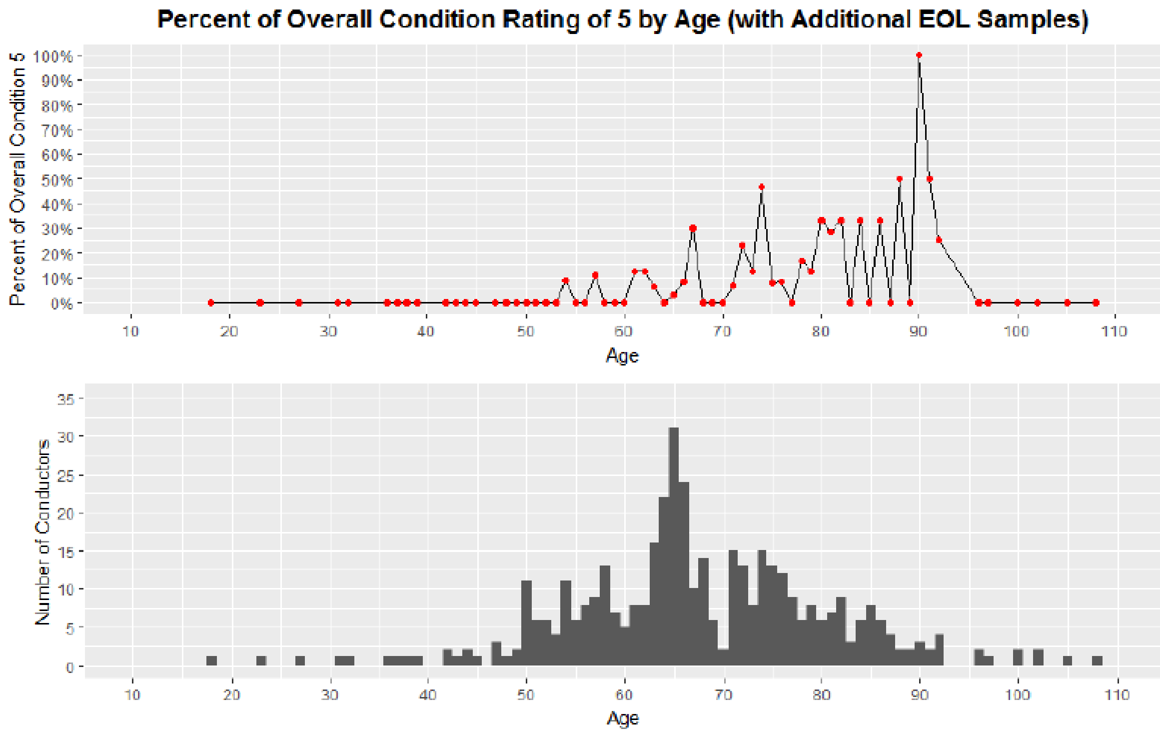

Figure 3-82
Percent of Samples with OCS Rating of 5 by Age (All ACSR)

With no success in finding a useful age dependent progressive degradation model, investigators turned to modeling the final degradation state (condition 5) as a function of age and applied EPRI's Bayesian failure analysis approach to model the assessed end-of-life condition rate as a function of age based on the provided data. A separate analysis that models end-of-life or near end of life (condition 5 or 4) as a function of age was also performed. A third analysis was conducted using in service and replacement demographic data.

4
MODELING OF ASSESSED CONDITION AS A FUNCTION OF AGE

Assessment/Replacement Time versus State Change

An important characteristic of assessment data such as that provided for Hydro One conductor condition is that the only known time is that associated with the condition measurement, not the time at which a particular condition was reached. With reference to Figure 4-1, we only know conductor condition at the time of assessment or replacement (t_1), and do not know the time of state change t_0, which most likely occurred sometime before the time of assessment or replacement (t_1).

To accommodate this characteristic, EPRI developed software to model the event of state change, i.e. reaching condition(s) requiring replacements, with known assessment or replacement times but unknown state change time (t_0).

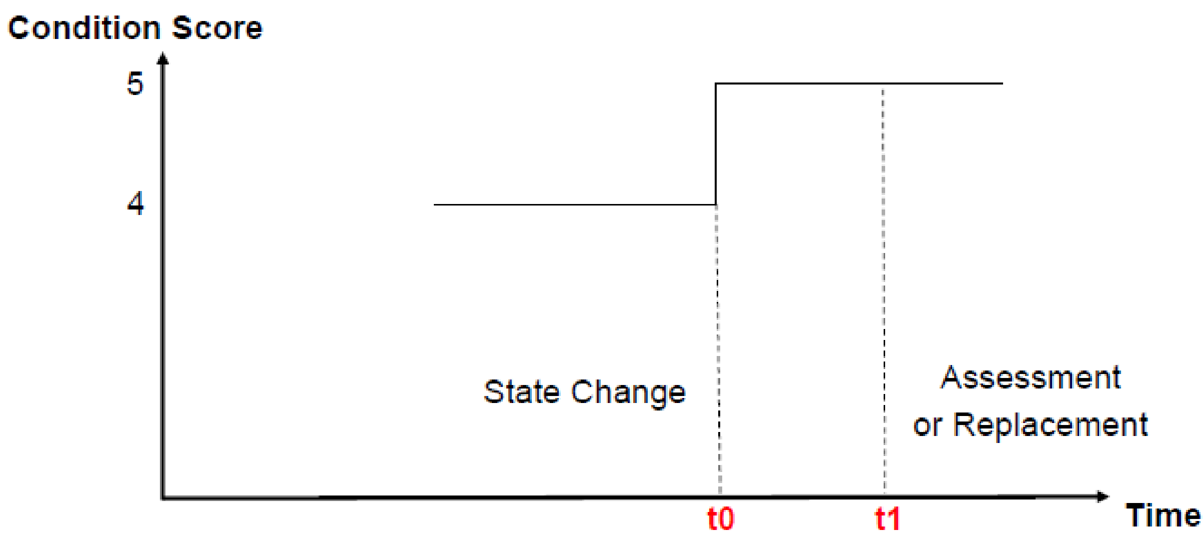

Figure 4-1
Assessment or Replacement Time versus State Change

The replacement and in-service data included line sections with widely different lengths. Consequently, all line sections (both replacement and in-service) were weighted in proportion to the corresponding line section lengths in kilometers, rounded to the nearest integer. For example, a line section with a length of 11.3 km was assigned a weight of 11, i.e. represented by 11 samples in the input data to the model. Note that line sections with section length less than 0.5 km (totaling just 0.6% of the total installed length of the entire ACSR fleet) were assigned a weight of zero and therefore excluded from analysis. With this exclusion, the weighted average age across ACSR line sections increases by less than 0.05 years. One may conclude that not including these segments of less than 0.5 km length has no material effect on the analysis.

Data Sources Summary

The three analyses performed with the provided data are shown diagrammatically in Figure 4-2.

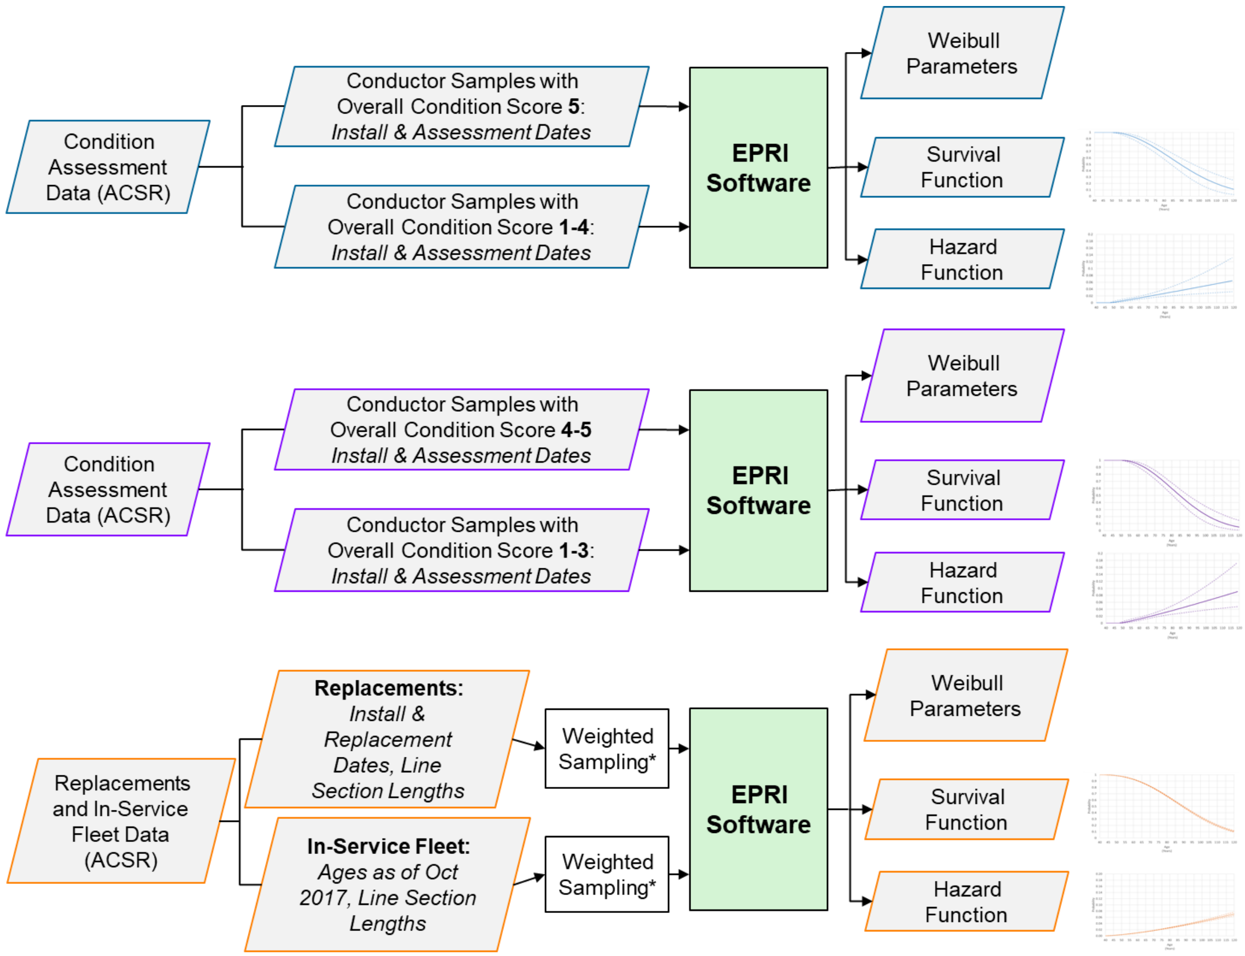

Figure 4-2
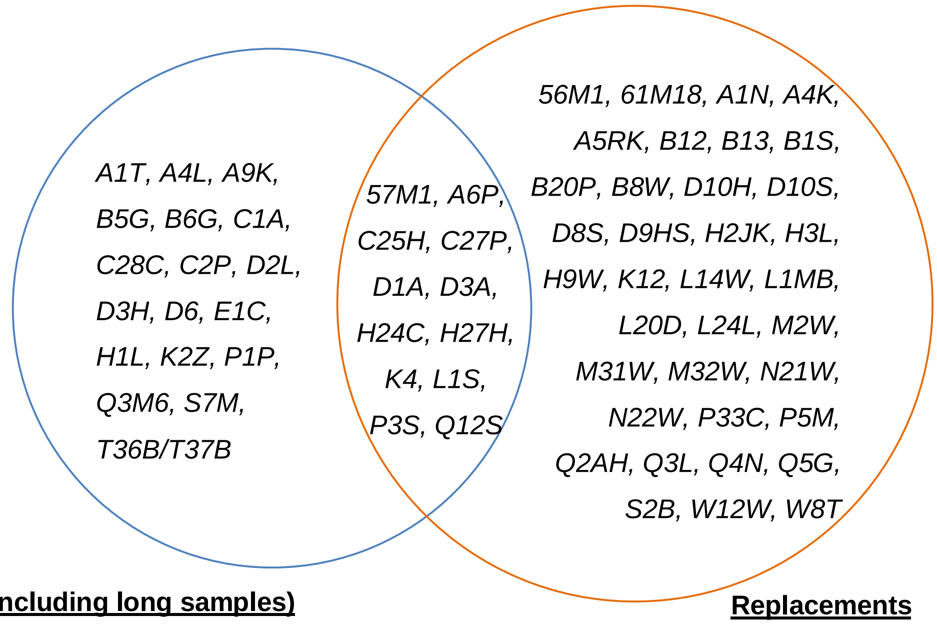
Analyses Performed

Figure 4-3 recaps the unique circuits, total number of entries, and collection periods associated with the OCS 5 data set (including long samples) and replacement records data set.



OCS 5 (including long samples)
30 circuits represented, 12 of which are shared with replacement records
(44 entries total, spanning January 2001 - December 2016)

Replacements
48 circuits represented, 12 of which are shared with OCS 5
(126 entries total, spanning January 1988 - January 2017)

Figure 4-3
Venn Diagram Showing Circuits, Number of Data Entries, and Collection Periods Associated with the OCS 5 Samples and Replacement Records Data Set, along with Their Intersections

The following table shows comparisons of the analysis results of the mean Weibull hazard function parameters and median life derived from replacement and in-service fleet data and condition assessment data. Subsequent figures show analysis results on hazard and survival functions derived from these two data sources.

Table 4-1
Weibull Hazard Model Results for the Analyses Shown in Figure 4-2

Life Event Modeled	Input Data	Mean Weibull Parameters			Median Life (years)
		Shape	Scale	Location	
Replacements	Replacement & in-service fleet data	2.46	57.4	40.0	~ 89.5
Reaching EOL condition (5)	Condition assessment data	1.71	47.0	53.0	~ 91.0
Reaching EOL condition (5) or near EOL condition (4)	Condition assessment data	2.02	33.0	46.0	~ 73.5

Note that scale parameter results for the EPRI approaches are based on Weibull distributions shifted by a corresponding location parameter. The location parameters for each model were determined by the youngest aged sample to have experienced the hazard in each cohort. Based on the provided data, EOL conditions do not occur before age 53, near EOL conditions do not occur before age 46, and replacements generally do not occur before age 40. Care should be taken when interpreting these results, e.g. for the analysis using the replacements and in-service fleet data, the model suggests 63% of the population will reach condition(s) requiring replacement by Age 97.4, (57.4 {scale} + 40.0 {location}). Values for shape and scale shown are means.

Once the Weibull function parameters are determined, other useful functions, as presented in the following figures, can be derived. In all cases, the dotted lines represent 95% confidence bands.

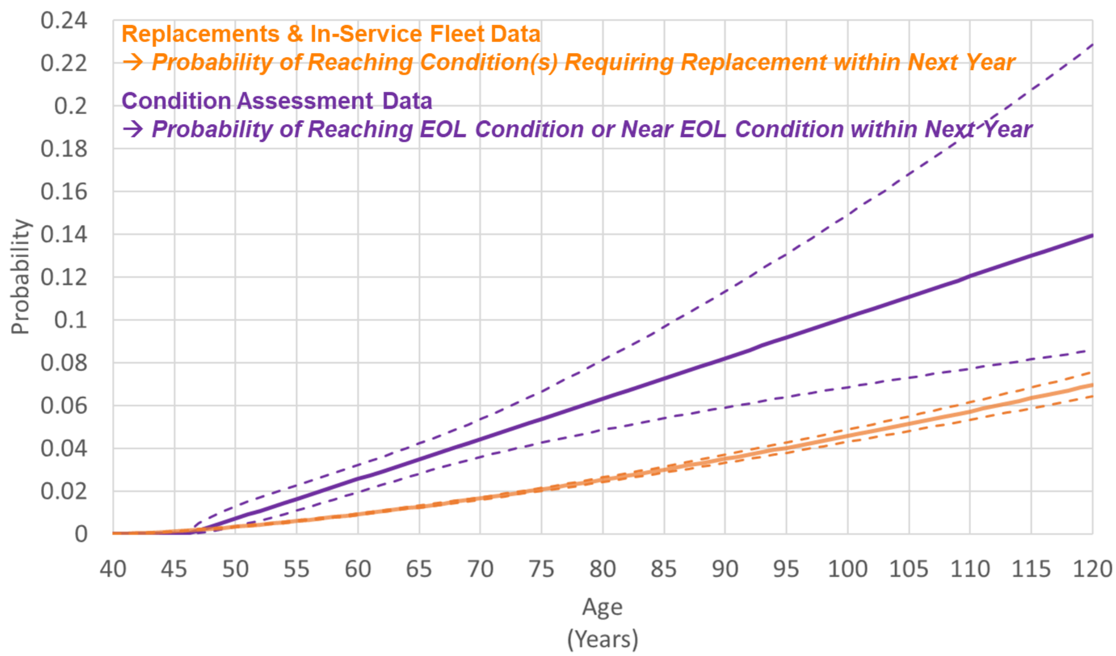

Figure 4-13
Comparison of Hazard Functions Derived from Replacements and In-Service Data and Condition Assessment Data (OCS 5 or 4)

Summary of Analysis Results

The OCS 5 and the replacement analysis results, although obtained from different data sources (condition assessment vs replacement/in-service), are in good agreement. As shown in Figure 4-3, the overlaps between the two data sources in terms of time periods and circuits represented are limited. These limited commonalities between these two data sources along with the good agreement of their results provide evidence that suggests the replacements data can be a good proxy for the condition assessment data.

5
DISCUSSION AND APPLICATIONS OF MODELING RESULTS

Comparison with Results from Hydro One 2014 Asset Failure Analysis (Foster Associates, 2014)

The Foster study provided by Hydro One included the following two sets of results:

- Iowa (non-parametric) curves
- Weibull (parametric) model

EPRI Weibull results and the Foster Iowa (non-parametric) survival curve (with a median life of about 87) are reasonably close (see Figure 5-1 for Foster Iowa survival curve).

However, the Weibull model results included in the Foster report presented a largely unrealistic scenario. As shown in Figure 5-2, the survival function derived from Foster's Weibull model suggests that conditions requiring replacement are not reached until after age of 150, and that all will have reached such conditions by age of 190 (with a median life of around 170).

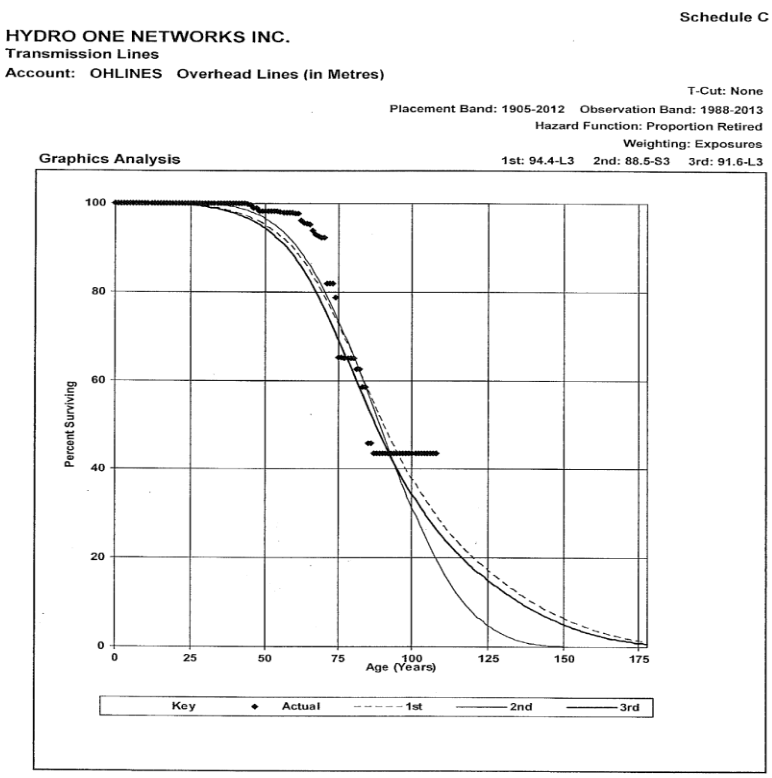

Figure 5-1
Non-parametric (Iowa) Survival Curve *Hydro One 2014 Asset Failure Analysis* (Foster Associates, 2014)

Survival Function for Weibull Model Included in Foster Report

EPRI Projected ACSR Replacements (km) within Next 1-5 Years Based on Replacements Data and Condition Assessment Data

One may convolute a given age dependent hazard rate with demographic data of an in-service fleet to develop projections of the total amount of conductor lengths that would experience the hazard. It is important to note that such projections provide estimates for the population as a whole and not information on any individual segments. These projections are forward looking estimates based on the ages of currently installed segments.

A series of projections were developed from the three EPRI Weibull models (condition assessment OCS 5, condition assessment OCS 5 or 4, and replacements) and the in-service ACSR fleet line segment ages and lengths, as shown in Figures 5-3 through 5-5. The projections provide cumulative estimates of circuit-kilometers expected to reach a condition warranting replacement (derived from replacements/in-service fleet data) or OCS 5 (derived from OCS 5 condition assessment data) by year. Projections for cumulative estimates of circuit-kilometers expected to reach OCS 5 or 4 were also included in these figures (derived from OCS 5 or 4 assessment condition data). The numbers provide the mean values and the vertical lines the 95% confidence bands. Each set of projections were calculated by convoluting installed lengths by age (the in-service fleet) and age dependent replacement rates derived from the corresponding EPRI Weibull model.

EPRI Cumulative Estimates of ACSR Circuit-km Expected to Reach a Condition Requiring Replacement, OCS 5, or OCS 5 or 4 within Next 1-5 Years Based on Replacements Data and Condition Assessment Data

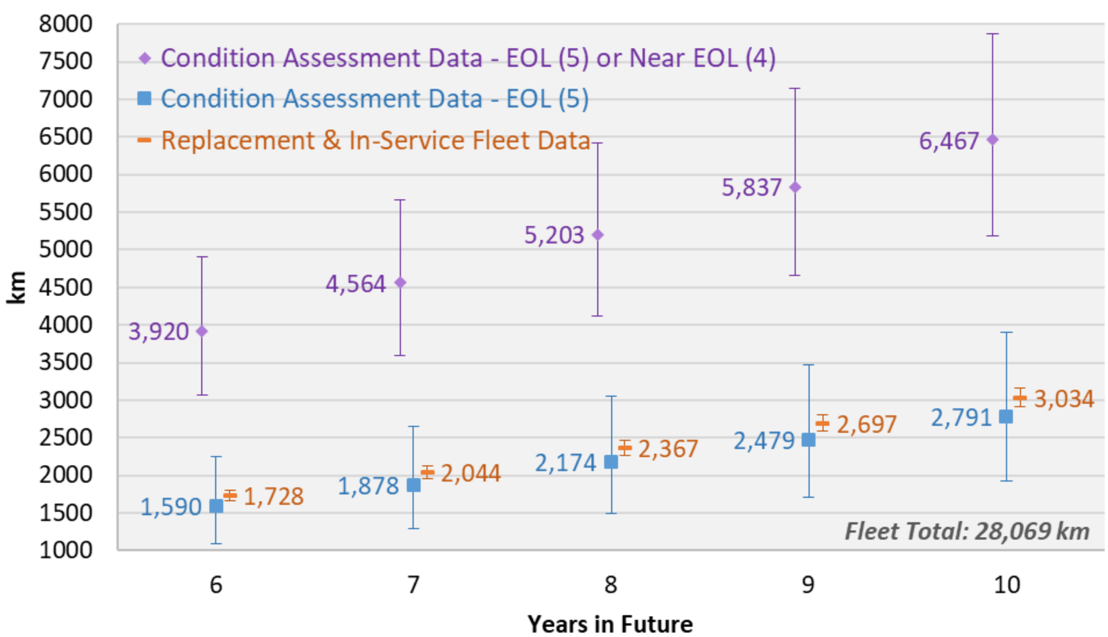

Figure 5-4
EPRI Cumulative Estimates of ACSR Circuit-km Expected to Reach a Condition Requiring Replacement, OCS 5, or OCS 5 or 4 within Next 6-10 Years Based on Replacements Data and Condition Assessment Data

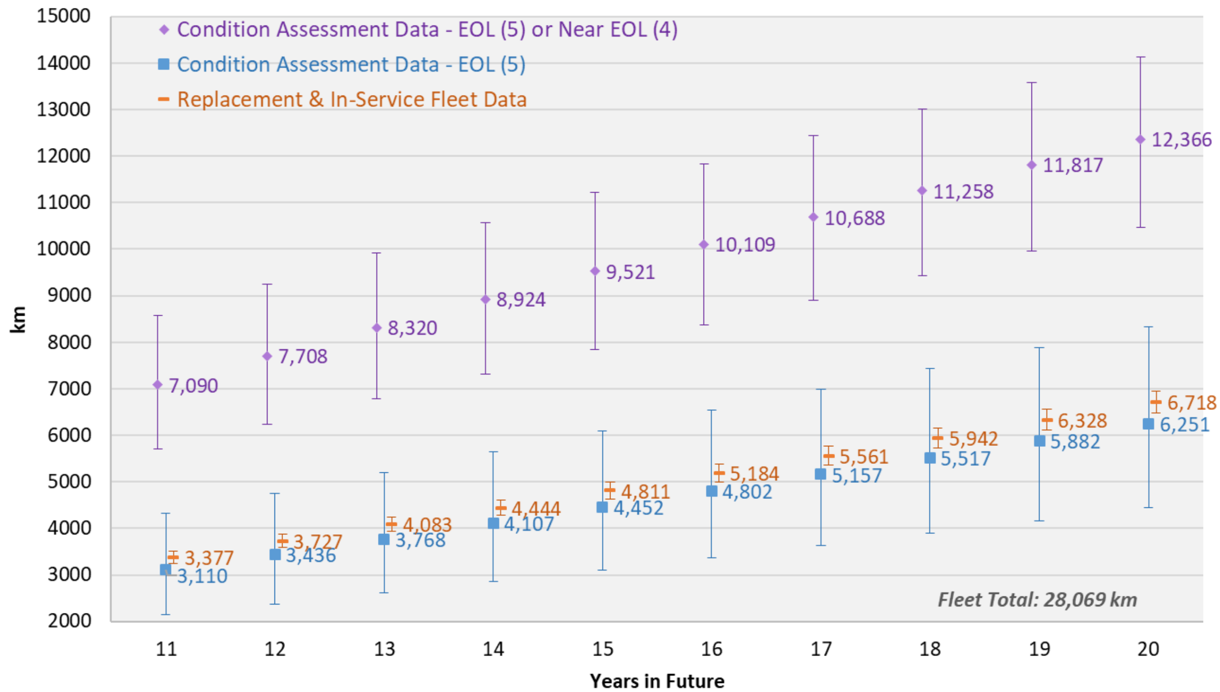

Figure 5-5
EPRI Cumulative Estimates of ACSR Circuit-km Expected to Reach a Condition Requiring Replacement, OCS 5, or OCS 5 or 4 within Next 11-20 Years Based on Replacements Data and Condition Assessment Data

Table 5-1 provides mean values (with 95% confidence bands) for the 5, 10, and 20 year projections associated with the different data sources and life events modeled.

Table 5-1
EPRI Cumulative Estimates of ACSR Circuit-km Expected to Reach a Condition Requiring Replacement, OCS 5, or OCS 5 or 4 within Next 5, 10, and 20 Years

Life Event Modeled	Input Data	Projection Means (and 95% Confidence Bands) in km		
		5 Years	10 Years	20 Years
Replacements	Replacement & in-service fleet data	1,420 (1,362, 1,481)	3,034 (2,915, 3,156)	6,718 (6,486, 6,952)
Reaching EOL condition (5)	Condition assessment data	1,311 (892, 1,863)	2,791 (1,922, 3,899)	6,251 (4,439, 8,340)
Reaching EOL condition (5) or near EOL condition (4)	Condition assessment data	3,273 (2,552, 4,123)	6,467 (5,182, 7,867)	12,366 (10,468, 14,134)

General Discussion

The conductor Condition Assessment (Score) data used are not from random samples.

For the replacements data, it is unclear whether all replacements were due to failures or lines reaching condition(s) that warrant replacements or some other reasons. Analysis results from such data can potentially be pessimistic. However, the similarity between results based on condition assessment data and results based on replacements data lead one to believe that such a concern is not necessarily warranted, especially when the commonalities between the two data sources in terms of time periods and circuits represented are limited (as discussed previously and shown in Figure 4-3).

6
CONCLUSIONS

No useful correlation was found relating conductor condition assessments to the various measured assessment factor parameters. The result was that no age-dependent progressive degradation model (i.e. one that would model the progression from condition 1 to 2, 2 to 3, etc.) could be developed. With no success in finding a useful progressive degradation model, investigators turned to modeling only the final degradation state (condition 5) as a function of age and applied EPRI's Bayesian failure analysis approach to model the assessed end-of-life condition rate pattern based on the provided data.

The good agreement between the two EPRI Weibull models derived from "failed" condition assessment data and historical replacements suggests that these models provide a fairly accurate description of past conductor performance as a function of age. The model validity is further strengthened with the general agreement with the Foster non-parametric analysis results. It is important to note that these models are probabilistic descriptions of populations. With reference to Figure 4-4, the ACSR conductor fleet mean age for reaching the EOL condition (OCS 5) is about 91 years.

Unless there is some dramatic change in the stressors leading to degradation (e.g. loading), it is reasonable to expect future performance to continue to fit these age-related models. Combining these age-dependent hazard rate models with the ages of the in-service conductor lengths can provide an estimate of the conductor lengths that would reach a condition warranting replacement (based on historical criteria) in future years. These are population-based results and provide guidance for fleet decisions.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc.(EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.
